PREFACE & Acknowledgements

The twelfth thoroughly revised and enlarged edition of **Modern's abc of Physics** was brought out in March, 2002 for Class XII of Senior Secondary Certificate Examination of C.B.S.E. and School Education Boards of other Indian States. It is really heartening and satisfying for the author that the new features of the book earned a great appreciation from both the students and the learned colleagues of various schools and colleges. In the present edition, the text has been thoroughly revised and recast to make it more systematic and uptodate.

Salient Features of the Book

- The whole text has been arranged strictly according to N.C.E.R.T. pattern.
- To provide clarity of the subject, the whole text is studded with **The jargon** (to define and introduce a new physical term), **Key point** (to highlight the important concept in an article), **Watch out** (to make distinction between the physical meaning of a term and its meaning in everyday life) and **Self-test Question** (to enable the students to test their grip on the article).
- The article work in each chapter of a unit is coupled with well graded and carefully selected **Solved Numerical Problems**.
- **Very Short Answer Questions** and **Short Answer Questions** set in various Board Examinations have been throughly scanned and incorporated in the book with proper Answers/Hints.
- Under the heading **Techie-Stuff**, a good number of both **Conceptual Numerical Problems** and **Conceptual Short Answer Questions** have been provided for ambitious, brilliant and curious students with an aim to inculcate the much needed urge and desire in such student to probe the subject more deeply.
- **Unsolved Numerical Problems for Self-practice** have been categorised into various types, so as to enable the students to choose the appropriate formula with ease.
- **Competitive Examination File** at the end of each unit forms another special feature of the book.

  Revision at a Glance provides an overview of the contents of a unit for easy and handy reference of various physical laws, principles, terms and formulae dealt in the unit.

  Numerical Problems from Competitive Examinations, such as I.I.T., Roorkee and I.S.M., Dhanbad have been provided with solutions by adopting a novel technique in the form of **Thought Process**. Armed with this technique, the students will be able to attack the otherwise brainteasing and seemingly incomprehensible numerical peoblems with great ease.

  Multiple Choice Questions set in various competitive examinations, such as C.B.S.E., A.I.I.M.S., A.F.M.C., M.N.R., C.P.M.T., I.I.T., etc have been thoroughly covered in the book. So that students can prepare them easily, these questions have been categorised into **Text-Based** and **Thought-Based** Multiple Choice Questions.

Acknowledgements

The author owes his sincere thanks to Sh. Ashok Malhotra, Managing Director and Sh. S.K. Sikka, Manager, Modern Publishers for the keen interest they have taken to give the book its present shape. The author gratefully acknowledges the tremendous efforts on the part of Ishara Laser Graphics for doing a neat laser setting job. Mr. Rakesh Rana has done a great job of doing a neat diagram work. The author wishes to thank them for their help.

Suggestions for further improvement of the book will be gratefully acknowledged and incorporated in the next edition.

FACE TO FACE

It is a general feeling among both the teachers and the taught that the numerical problems that are set in the Competitive Examinations for admission to I.I.T., Roorkee and some other Engineering Colleges are so intricate in nature that they become seemingly incomprehensible. But clue to the problem is always somewhere in the cacoon of it. Therefore, in order to train the students to dig out that much vital clue, **Thought Process** has been given just before the formal solution of such a menacing problem. Thought Process will enable the students to prepare a proper line of attack for the problem. The same approach has been followed in case of a few Conceptual Numerical Problems also. The author firmly believes that armed with this technique, the students will be able to attack the otherwise much mind-boggling problems with great ease and rare confidence and the problem will simply surrender before him/her.

Wishing you a Happy Numerical Problems Solving.

To keep pace with the fast changing intellectual climate, the author invites the readers to visit the book site on the Internet. The on line addition of this book is an attempt to reach out to the students so as to keep them abreast with the latest questions set in the various examinations. With this factility the readers can have a direct interaction with the author through e-mails. It is a direct outcome of the deliberations between Mr. Sameer Jain, my son-in-law and Sh A.K. Malhotra, the dynamic publisher.

SYLLABUS

Central Board of Secondary Education, Delhi

CLASS XII (2003 – 04)

One Paper **Time : 3 Hours** **70 Marks**

I.	Electrostatics	8
II.	Current Electricity	8
III.	Magnetic Effects of Current and Magnetism	8
IV.	Electromagnetic Induction and Alternating Current	8
V.	Electromagnetic waves	3
VI.	Optics	10
VII.	Dual Nature of Matter and Radiation	4
VIII.	Atomic Nucleus	6
IX.	Solids and Semiconductor Devices	8
X.	Principles of Communication	7
	Total	70

Unit I : Electrostatics (Periods 22)

- Frictional electricity, charges and their conservation; Coulomb's law - Forces between two point electric charges, Forces between multiple electric charges; Superposition principle and continuous charge distribution.

Electric field and its physical significance, electric field due to a point charge, electric field lines; Electric dipole, electric field due to a dipole and behaviour of dipole in a uniform electric field.

Electric potential-physical meaning, potential difference, electric potential due to a point charge, a dipole and system of charges; Equipotential surfaces, Electrical potential energy of a system of two point charges and of electric dipoles in an electrostatic field.

Electric flux, statement of Gauss's theorem and its applications to find field due to infinitely long straight wire, uniformly charged infinite plane sheet and uniformly charged thin spherical shell.

Conductors and insulators, presence of free charges and bound charges inside a conductor; Dielectrics and electric polarisation, general concept of a capacitor and capacitance, combination of capacitors in series and in parallel, energy stored in a capacitor, capacitance of a parallel plate capacitor with and without dielectric medium between the plates; Van de Graff generator.

Unit II : Current Electricity (Periods 22)

- Electric current, flow of electric charges in a metallic conductor, drift velocity and mobility, and their relation with electric current; Ohm's law, electrical resistance, V–I characteristics, Exceptions of Ohm's law (Non-linear V–I characteristics), electrical resistivity and conductivity, classification of materials in terms of conductivity; Superconductivity (elementary idea); Carbon resistors, colour code for carbon resistors; combination of resistances - series and parallel. Temperature dependence of resistance. Internal resistance of a cell, Potential difference and e.m.f. of a cell, combination of cells in series and in parallel.

Kirchhoff's law–Illustration by simple applications, Wheatstone bridge and its applications for temperature measurements, Metre bridge–special case of Wheatstone bridge.

Potentiometer–principle and applications to measure potential difference and for comparing e.m.fs. of two cells.

Electric power, thermal effects of current and Joule's law; Chemical effects of current–Faraday's laws of electrolysis; Electro-chemical cells–Primary and secondary cells, solid state cells.

Thermoelectricity–origin, elementary ideas of Seebeck effect, Thermocouple, Thermo-emf, neutral and inversion temperatures. Measurement of temperature using a thermocouple.

Unit III : Magnetic Effect of Current and Magnetism (Periods 22)

- Concept of magnetic field. Oersted's experiment, Biot-Savart law, magnetic field due to an infinitely long current carrying straight wire and a circular loop ; Ampere's circuital law and its applications to straight and toroidal solenoids ; Force on a moving charge in uniform magnetic and electric fields, Cyclotron ; Force on current–carrying conductor in a uniform magnetic field. Forces between two parallel current carrying conductors–definition of ampere ; Torque experienced by a current loop in a uniform magnetic field, moving coil galvanometer–its current sensitivity and conversion to ammeter and voltmeter.

Current loop as a magnetic dipole and its magnetic dipole moment ; Magnetic dipole moment of a revolving electron; Magnetic field intensity due to magnetic dipole (bar magnet) along the axis and perpendicular to the axis ; Torque on a magnetic dipole (bar magnet) in a uniform magnetic field ; Bar magnet as an equivalent solenoid, Magnetic field lines ; Earth's magnetic field and magnetic elements ; Para, dia and ferromagnetic substances with examples, Electromagnets and permanent magnets.

Unit IV : Electromagnetic Induction and Alternating Current (Periods 18)

- Electromagnetic induction, Faraday's laws, Induced e.m.f. and current, Lenz's law, Eddy currents, self and mutual inductance.

Alternating current, peak and r.m.s. value of alternating current/voltage, reactance and impedance ; LC-oscillations, LCR series circuit (Phasor diagram) – Resonant circuits and Q-factor; Power in a.c. circuits, wattless current.

a.c. generator and transformer.

Unit V : Electromagnetic Waves (Periods 7)

- Electromagnetic waves and their characteristics (qualitative ideas only); Transverse nature of electromagnetic waves.

Electromagnetic spectrum (Radio, microwaves, infra-red, optical, ultra-violet, X-rays, gamma rays) including elementary facts about their uses; Propagation of electromagnetic waves in atmosphere.

Unit VI : Optics (Periods 26)

- Refraction of light, total internal reflection and its applications, spherical lenses, thin lens formula, lens maker's formula; Magnification, Power of a lens, combination of thin lenses in contact; Refraction and dispersion of light due to a prism, Scattering of light – Blue colour of the sky and reddish appearance of the sun at sun-rise and sun-set.

Optical instruments–Compound microscope, astronomical telescope (refraction and reflection type) and their magnifying powers.

Wave front and Huygens' principles ; Reflection and refraction of plane wave at a plane surface using wave fronts (qualitative idea) ; Interference – Young's double slit experiment and expression for fringe width, coherent sources and sustained interference of light; Diffraction – diffraction due to a single slit, width of central maximum, difference between interference and diffraction ; Resolving power of microscope and telescope; Polarisation, Plane polarised light, Brewster's law ; Use of plane polarised light and polaroids.

Unit VII : Dual Nature of Matter and Radiation (Periods 6)

- Photo-electric effect, Einstein's Photo-electric equation—particle nature of light, photo-cell, Matter waves – wave nature of particles, de-Broglie relation, Davisson and Germer experiment.

UNIT VIII: Atomic Nucleus (Periods 12)

- Alpha-particle scattering experiment, size of the nucleus, composition of the nucleus – protons and neutrons. Nuclear instability – radioactivity – alpha, beta and gamma particles/rays and their properties, radioactive decay law, simple explanation of α-decay, β-decay and γ-decay. Mass-energy relation, mass defect, Binding energy per nucleon, its variation with mass number, Nature of nuclear forces, nuclear reaction – Nuclear fission and Nuclear fusion.

UNIT IX : Solids and Semiconductor Devices (Periods 18)

- Energy bands in solids (qualitative ideas only), difference between metals, insulators and semi-conductors using band theory; Intrinsic and extrinsic semi-conductors, *p-n* junction, Semiconductor diode – characteristics in forward and reverse bias, diode as a rectifier, solar cell, photo-diode, LED, zener diode as a voltage regulator; Junction transistor, transistor action, characteristics of a transistor; Transistor as an amplifier (common-emitter configuration) and oscillator; Logic gates (OR, AND, NOT, NAND and NOR); Elementary ideas about I.C.

UNIT X : Principles of Communication (Periods 20)

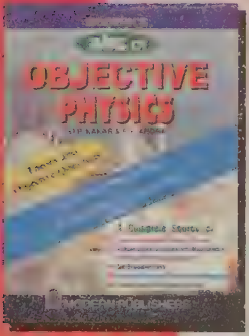
- Elementary idea of analog and digital communication ; Need for modulation; Modulation – amplitude, frequency and pulse modulation; Elementary idea about demodulation, Data transmission and retrieval – Fax and Modem.

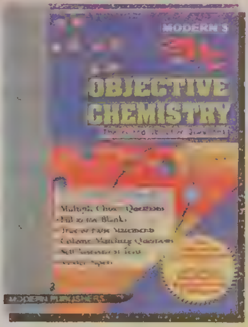
Space Communication : Propagation of e.m. waves in atmosphere. Sky and space wave propagation. Satellite communication. Applications in remote sensing.

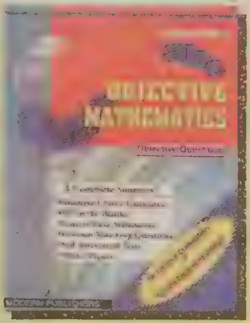
Line Communication : 2-wire lines, cables, telephone links; optical communication (optical fibre, Lasers), elementary principle of light modulation.

UNDOUBTEDLY NO.1

TO ENSURE YOUR ENTRANCE
in Engineering, IIT and Medical







Modern's abc of

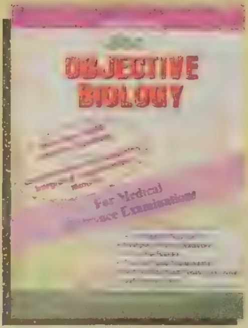
- Objective Physics
- Objective Chemistry
- Objective Mathematics
- Objective Biology

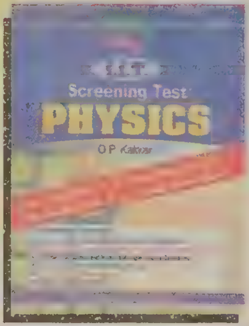
IIT Screening Test

- Physics
- Chemistry
- Sample Papers

A Complete Source of

- Precise discussion of chapters, emphasising all basic principles, definitions, diagrams, terms and analytical relations.
- Exclusive Numerical Problems (Solved).
- Multiple Choice Questions with miscellaneous MCQ's (with Hints and Solutions).
- Fill in the Blanks and True or False Statements.
- Self Evaluation Tests.
- Practical Model Test Papers.
- Coverage of previous years' objective and subjective questions of various examinations.





- All questions have been picked up from the various entrance exams.
- Also cover the most tricky and difficult questions.
- The most exhaustive books ever published.
- Modern's abc Series Always First with the Best

Unmistakably and undoubtedly the best books on the subjects. You can 100% depend on these books to ensure your admission in Medical and Engineering Colleges. This is not a self praise. A thorough study of the books will definitely convince you about their true worth.

CHAPTER 1

Coulomb's Law

1.01. FRICTIONAL ELECTRICITY

In 600 B.C., the Greek philosopher Thales observed that amber, when rubbed vith wool, acquires the property of attracting objects like small bits of paper, dry eaves, dust particles, etc. There are many other substances like amber, which can lso acquire the property of attracting such light objects on being rubbed with uitable substances. For example, a glass rod on being rubbed with silk, an ebonite od on being rubbed with fur, a plastic comb on being run through dry hair, etc. The amber, glass rod, ebonite rod or plastic comb are said to be ***electrified*** or ***charged vith electricity***. Wool (in case of amber), silk (in case of glass rod) and fur (in case f ebonite rod) are also found to be electrically charged.

The electricity developed on objects, when they are rubbed with each other, is called rictional electricity.

The electric charges so developed cannot move from one part of the object to he other part. For this reason, frictional electricity is also known as ***static electricity***.

The jargon . . . . .

Amber is a yellow resinous substance. It is a hardened sap of a tree – similar to a pine tree. In Greek, the meaning of amber is ***electrum*** and probably the words like, electricity, electric charge, electric field, electric potential and finally electron owe their origin to electrum.

1.02. TWO KINDS OF ELECTRIC CHARGES

To show that electric charges are of two types, take a glass rod and suspend it vith a thread after rubbing it with silk. If another glass rod rubbed with silk is rought near it, the two rods are found to repel each other. In the same fashion, two bonite rods each rubbed with fur are also found to repel each other. But when an bonite rod rubbed with fur is brought near a glass rod rubbed with silk, the two ods are found to attract each other. The above observations lead to the following wo conclusions :

1. The electric charge developed on glass rod (rubbed with silk) is different from he charge developed on ebonite rod (rubbed with fur).

2. The electric charges of same kind (charges developed on two glass rods or on two ebonite rods) repel each other, while those of different kinds (charges leveloped on a glass rod and an ebonite rod) attract each other.

Key point ✓

Like charges repel each other and unlike charges attract each other.

Historically, the electric charge developed on ebonite rod (or amber) was called ***esinous,*** while the charge developed on glass rod was ***viterous***. The American cientist Benjamin Franklin introduced the concept of positive and negative charges n order to distinguish the two kinds of charges. He named viterous as positive harge and resinous as negative charge.

Self-test Question ?

Consider three objects A, B and C. A and B repel each other, while A and C attract. What is the nature of force between B and C ?

As said earlier, when glass rod is rubbed with silk, silk is also found to be lectricially charged. It is found that the nature of charge on silk is opposite to that on glass rod. Thus, when glass rod is rubbed with silk, the glass rod becomes ositively charged and silk negatively charged. In the same manner, when an ebonite od is rubbed with fur, ebonite rod becomes negatively charged and fur positively harged.

The jargon . . . . .

The charge developed on amber was called ***resinous***, as amber is a resin.

In the table given below, if an object in first column is rubbed against the object iven in second column, the object in first column will acquire positive charge, while hat in second column will acquire negative charge :

The name of the object, which acquires	
positive charge	**negative charge**
Glass rod	Silk cloth
Fur or catskin	Ebonite rod
Woollen cloth	Amber
Woollen cloth	Rubber shoes
Woollen cloth	Plastic object

Obviously, if the two charged objects are from the same column, they will repel each other and if the two charged objects are from two different columns, they will attract each other.

1.03. ELECTRIC CHARGE

All the substances are made of small particles called atoms, which are made of three elementary particles namely electrons, protons and neutrons. Because of their masses, these particles exert ***gravitational forces*** on each other. However, in addition to gravitational force, protons and electrons exert an extra force on each other, which is quite large as compared to gravitational force. This extra force is called ***electric force***. Therefore, apart from their masses, protons and electrons must possess some additional intrinsic property.

The additional property of protons and electrons, which gives rise to electric force between them is called electric charge.

Electric charge is a scalar quantity. A proton possesses positive charge $+e$, while an electron possesses an equal negative charge $-e$, where

$$e = 1{\cdot}6 \times 10^{-19} \text{ coulomb}$$

Normally, an object contains equal number of protons and electrons and as such, it is electrically neutral. When the numbers of protons and electrons are not equal, the object possesses a net positive or negative charge.

Key point ✓

Electric charge is a scalar quantity. In SI, its unit is **coulomb (C)**.

1.04. ORIGIN OF ELECTRIC CHARGE IN FRICTIONAL ELECTRICITY

When two different objects (such as a glass rod and silk) are rubbed together, they get electrified. It happens due to transfer of electrons from one object to the other. The object which gains electrons becomes negatively charged, while the object which loses electrons becomes positively charged. The appearance of charges on the two bodies can be explained on the basis of atomic model.

According to atomic model, an atom consists of a central positive core, called ***nucleus***. The nucleus is made of protons and neutrons, which are held inside it with strong ***nuclear forces***. The electrons revolve around the nucleus in circular orbits. The number of electrons in an atom is equal to the number of protons in the nucleus. Since magnitude of charge on a proton and an electron is same, an atom is always electrically neutral. The electrostatic force of attraction between electrons and the nucleus is much weaker as compared to nuclear force between protons and neutrons constituting the nucleus. Because of this, whereas it is practically impossible to remove protons from the nucleus, electrons can be easily removed from an atom by supplying energy to them. The energy* required to remove an electron from the atom depends upon how tightly it is bound to the atom.

Let us now explain the appearance of charge on a glass rod and silk, when they are rubbed together. When a glass rod is rubbed with silk, energy is provided to overcome friction between them. The energy so provided tends to remove electrons from both the glass rod and silk. In a glass rod, electrons are less tightly bound as compared to those in silk. As a result, the electrons get removed from glass rod and are transferred to silk. As the glass rod loses electrons, it becomes positively charged. On the other hand, silk acquires an equal negative charge on gaining electrons. It, therefore, follows that in the charging process due to rubbing, the appearance of charges is due to actual transfer of electrons.

It may be pointed out that when two objects are charged by rubbing them together, the masses of both the objects change. It is because, electrons are material particles having a small finite mass and in the rubbing process, electrons are transferred from one object to the other. The positive charge appears on the object, which loses electrons. Hence, the mass of positively charged object is less than its original mass. On the other hand, the mass of negatively charged object is more than its original mass as the negative charge appears on it due to gain of electrons.

Key point

In frictional electricity, the charges on two objects rubbed together appear due to actual transfer of electrons (material particles) from one object to the other.

1.05. ADDITIVE NATURE OF CHARGE

We know that mass of an object is equal to the sum of the masses of its constituent particles. Owing to this, mass is said to be ***additive*** in nature. Like mass, electric charge also possesses additive property.

The total electric charge on an object is equal to the algebraic sum of all the electric charges distributed on the different parts of the object.

If q_1, q_2, q_3, ... are electric charges present on different parts of an object, then total electric charge on the object,

$$q = q_1 + q_2 + q_3 + \ldots\ldots$$

It may be pointed out that while taking the algebraic sum, the sign (positive or negative) of the electric charges must be taken into account.

Self-test Question

An object contains n_1 protons and n electrons. What is the net charge on th object ?

The additive property of mass and electric charge differ on following two accounts :

1. The masses of the particles constituting an object are always positive, whereas the charges distributed on the different parts of the object may be positive or negative.

2. The total mass of an object is always non-zero, whereas the total charge on the object may be positive, zero or negative.

1.06. QUANTIZATION OF CHARGE

The magnitude of charge on a proton or an electron ($e = 1{\cdot}6 \times 10^{-19}$ C) is called elementary charge. Since protons and electrons are the only charged particles constituting the matter, the charge on an object must be integral multiple of $\pm e$. In other words, the charge possessed by an object cannot be a fraction of $\pm e$. Mathematically, the charge on any object must always be equal to

$$q = \pm n e,$$

where n is an integer. Further, the charge on an object can be increased or decreased in steps of e. It is known as ***quantization of charge*** or ***discrete nature of charge***.

The fact that all observable charges are always some integral multiple of elementary charge e (= $\pm 1{\cdot}6 \times 10^{-19}$ *C) is known as quantization of charge.*

The grainness or discrete nature of electric charge is usually not observable in actual partice. It is because, step size e of electric charge is very small. Due to this, number of elementary charges involved becomes extremely large, even when the electric charge on an object is changed by a very small amount. For example, when a glass rod is rubbed with silk, a charge of the order of one microculomb ($= 10^{-6}$ C) appears on the glass rod or silk. Since one elementary charge is equal to $1{\cdot}6 \times 10^{-19}$ C, the number of elementary charges on glass rod (or silk) is given by

$$n = \frac{10^{-6}\ \text{C}}{1{\cdot}6 \times 10^{-19}\ \text{C}} = 6{\cdot}25 \times 10^{12}$$

Key point ✓

The quantization effect of charge can be observed only at microscopic level.

Since it is a very large number, the quantization of charge is not observed. Contrary to it, one observes continuous variation in charge. The quantization of charge cannot be explained on the basis of classical theory.

Note. According to recent advancements in physics, it is now believed that protons and neutrons are themselves built out of more elementary units called ***quarks***. They are of two types. The up quark (u) carries charge $+2e/3$ and the down quark (d) has charge $-e/3$. A proton and neutron consist of three quarks each and likewise quark composition of a proton is ***u u d***, while that of neutron is ***u d d***. It may be clearly understood that even on quark model, the quantization of charge is not affected. It is only the step size of charge that decreases from e to $e/3$.

1.07. CONSERVATION OF CHARGE

Just as in mechanics, the total linear momentum of an isolated system always remains constant, the electric charge also obeys a similar law. It is called ***law of conservation of charge.***

It states that *for an isolated system, the net charge always remains constant.* In any physical pocess, the charge it may get transferred from one part of the system to another, but net charge will always remain the same. In other words, *charge can neither be created nor destroyed.*

The following examples explain the law of conservation of charge :

1. We know that when a glass rod is rubbed with silk, glass rod becomes positively charged and silk becomes negatively charged. The amount of positive charge on glass rod is found to be exactly the same as negative charge on silk. Thus, the system of glass rod and silk, which had zero net charge before rubbing, still possesses zero net charge after rubbing.

2. In all nuclear transformations, the proton number is found to remain unchanged. For example, in nuclear fission of uranium (${}_{92}\text{U}^{235}$) by a neutron (${}_{0}n^{1}$), barium (${}_{56}\text{Ba}^{141}$), krypton (${}_{36}\text{Kr}^{92}$) and three neutrons are produced along with liberation of energy. The nuclear reaction may be represented as below :

$$ {}_{0}n^{1} + {}_{92}\text{U}^{235} \longrightarrow {}_{56}\text{Ba}^{141} + {}_{36}\text{Kr}^{92} + 3\,{}_{0}n^{1} + \text{energy}$$

Proton number before fission $= 0 + 92 = 92$

Proton number after fission $= 56 + 36 + 3(0) = 92$

Thus, net charge (proton number) is same before and after the nuclear fission of U^{235}.

3. Annihilation of matter (a positron and an electron combine to produce a γ-ray photon) and pair production (a γ-ray photon materialises into an electron and positron pair) are two important nuclear phenomena. Charge is conserved in both the two processes.

1.08. PROPERTIES OF ELECTRIC CHARGE

The following are a few important properties of electric charge :

1. Like charges repel each other and unlike charges attract each other.

2. The magnitude of elementary negative or positive charge is same and is equal to $1{\cdot}6 \times 10^{-19}$ C.

3. The electric charge is ***additive*** in nature. It implies that total charge on an object is algebraic sum of the charges located at different points in the object.

4. The charge is ***quantized*** *i.e.* charge carried by a charged object is equal to $\pm\, n\, e$, where n is an integer.

5. The electric charge of a system is always ***conserved***.

6. Unlike mass, the electric charge on an object is not affected by the motion of the object.

Key point

The charge on an object is not affected by its motion.

1.09. COULOMB'S LAW IN ELECTROSTATICS

Coulomb's law in electrostatics is electrical analogue of Newton's law of gravitation. In 1785, Coulomb measured the force of attraction or repulsion between two electrical charges by using a torsion balance. His observations are known as ***Coulomb's law in electrostatics.***

It states that *two point charges attract or repel each other with a force which is directly proportional to the product of the magnitudes of the charges and inversely proportional to the square of the distance between them.*

The jargon

A force, which acts along the line joining the centres of two interacting objects, is called a central force.

The force is repulsive, if the charges are alike and attractive in case of unlike charges. Further, electrostatic force between two charges is ***central*** in nature. It may be pointed out that Coloumb's law in electrostatic holds for ***stationary*** charges. Further, the two charges should be ***points*** in size.

Key point

Coulomb's law in electrostatics holds for two point charges at rest.

Consider that two charges q_1 and q_2 are present at points A and B at a distance r apart as shown in Fig. 1.01. Then, force between the two charges *i.e.*

$$F \propto q_1 q_2 \qquad \text{...(1.01)}$$

$$\propto \frac{1}{r^2} \qquad \text{...(1.02)}$$

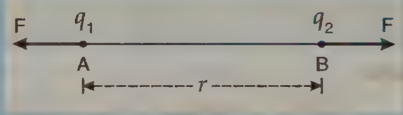

Fig. 1.01

Combining equations (1.01) and (1.02), we have

$$F \propto \frac{q_1 q_2}{r^2}$$

or

$$F = k\,\frac{q_1 q_2}{r^2}, \qquad \text{...(1.03)}$$

where k is constant of proportionality. Its value depends upon the nature of the medium in which the two charges are located and also the system of units adopted to measure F, q_1, q_2 and r.

In SI, when the two charges are located in vacuum or air,

$$k = \frac{1}{4\pi\varepsilon_0}$$

where ε_0 is called ***absolute permittivity of free space****. Therefore, from equation (1.03), the force between two charges located in air or vacuum is given by

$$F_{vac} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{r^2} \qquad \text{...(1.04)}$$

Self-test Question

Using equation (1.04), show that units of ε_0 are $C^2\,N^{-1}\,m^{-2}$.

The absolute permittivity of free space is measured to be

$$\varepsilon_0 = 8{\cdot}854 \times 10^{-12}\ C^2\,N^{-1}\,m^{-2}$$

$$\therefore \quad \frac{1}{4\pi\varepsilon_0} = \frac{1}{4\pi \times 8{\cdot}854 \times 10^{-12}\ C^2\,N^{-1}\,m^{-2}} = 9 \times 10^9\ N\,m^2\,C^{-2}$$

Hence, the equation (1.04) may be written as

$$F_{vac} = 9 \times 10^9 \times \frac{q_1 q_2}{r^2} \quad \text{(in newton)} \qquad \text{...(1.05)}$$

Key point

Another unit[†] of ε_0 is farad metre^{-1} (F m^{-1}).

---

* The absolute permittivity of air is only 1·005 times as that of free space (vacuum). For this reason, ε_0 is usually taken as absolute permittivity of both free space and air.

[†] Refer to section 5.04 of the chapter 5 on 'Capacitor.'

1.10. UNIT OF CHARGE

In SI, force between two charges q_1 and q_2 held in vacuum at a distance r apart is given by

$$F_{vac} = 9 \times 10^9 \times \frac{q_1 q_2}{r^2}$$

Suppose that $q_1 = q_2 = q$ (say) ; $r = 1$ m and $F_{vac} = 9 \times 10^9$ N

Then, $9 \times 10^9 = 9 \times 10^9 \times \dfrac{q \times q}{1^2}$

or $q^2 = 1$

or $q = \pm 1$ coulomb (C)

Therefore, *one coulomb is that charge which repels an equal and similar charge with a force of 9×10^9 N, when placed in vacuum (or air) at a distance of one metre from it.*

Note. 1. In electrostatic cgs system, the unit of charge is known as ***electrostatic unit of charge (e.s.u. of charge)***. It is also called *statcoulomb (stat C)*

$$\mathbf{1\ C = 3 \times 10^9\ stat\ C}$$

2. In electromagnetic cgs system, the unit of charge is known as ***electromagnetic unit of charge (e.m.u. of charge)***.

$$\mathbf{1\ C = \frac{1}{10}\ e.m.u.\ of\ charge}$$

Self-test Question

Prove that
1 coulomb = 3×10^9 statcoulomb

1.11. RELATIVE PERMITTIVITY (DIELECTRIC CONSTANT)

When two charges are situated in some other medium in place of air, the force between the charges may be greatly affected. For example, when the two charges are placed at the same distance in water, the force between the two charges becomes about $\frac{1}{80}$ th of the force between them, when the same two charges are located in air. It is because, absolute permittivity of water is about 80 times as large as the absolute permittivity of free space.

The force between two charges q_1 and q_2 located at a distance r in a medium may be expressed as

$$F_{med} = \frac{1}{4\pi\varepsilon} \cdot \frac{q_1 q_2}{r^2}, \qquad \text{...(1.06)}$$

where ε is called ***absolute permittivity*** of the medium.

The equation (1.04) gives force between the charges q_1 and q_2, when they are placed in vacuum at a distance r apart. Dividing equation (1.04) by (1.06), we have

$$\frac{F_{vac}}{F_{med}} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \Big/ \frac{1}{4\pi\varepsilon} \cdot \frac{q_1 q_2}{r^2} = \frac{\varepsilon}{\varepsilon_0} \qquad \text{...(1.07)}$$

Self-test Question

Do relative permittivity and dielectric constant of a medium imply different physical quantities ?

The ratio $\frac{\varepsilon}{\varepsilon_0}$ is denoted by ε_r, called ***relative permittivity*** of the medium w.r.t. vacuum. It is also denoted by K, called ***dielectric constant*** of the medium. Therefore, equation (1.07) gives

$$\varepsilon_r \text{ (or K)} = \frac{\varepsilon}{\varepsilon_0} = \frac{F_{vac}}{F_{med}} \qquad \text{...(1.08)}$$

Thus, *relative permittivity or dielectric constant of a medium may be defined as the ratio of the force between two charges placed at a certain distance apart in air to the force between the same two charges placed the same distance apart in that medium.*

Setting $\varepsilon = \varepsilon_0 \varepsilon_r$ or $\varepsilon = \varepsilon_0 K$ in equation (1.06), we have

$$F_{med} = \frac{1}{4\pi\varepsilon_0\varepsilon_r} \cdot \frac{q_1 q_2}{r^2}$$

or

$$F_{med} = \frac{1}{4\pi\varepsilon_0 K} \cdot \frac{q_1 q_2}{r^2} \qquad \text{...(1.09)}$$

Key point ✓

Two charges situated at a certain distance apart exert maximum force on each other, when they are placed in vacuum (or air). In a dielectric medium, the force between two charges always decreases.

1.12. COULOMB'S LAW IN VECTOR FORM

Consider that two like charges q_1 and q_2 are present at points A and B in vacuum at a distance r apart. The two charges will exert equal repulsive forces on each other. Let $\vec{F}_{12}$ be the force on charge q_1 due to charge q_2 and $\vec{F}_{21}$ be force on charge q_2 due to charge q_1[Fig. 1.02].

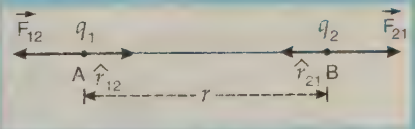

Fig. 1.02

According to Coulomb's law, the magnitude of force on charge q_1 due to q_2 (or on charge q_2 due to q_1) is given by

$$|\vec{F}_{12}| = |\vec{F}_{21}| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \qquad ...(1.10)$$

Let $\hat{r}_{12}$ be a unit vector pointing from charge q_1 to q_2 and $\hat{r}_{21}$, a unit vector pointing from charge q_2 to q_1. As the force vector $\vec{F}_{12}$ is along the direction of unit vector $\hat{r}_{21}$, we have

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \hat{r}_{21} \qquad ...(1.11)$$

Also, as the force vector $\vec{F}_{21}$ is along the direction of unit vector $\hat{r}_{12}$, it follows that

$$\vec{F}_{21} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \hat{r}_{12} \qquad ...(1.12)$$

The equations (1.11) and (1.12) express Coulomb's law in vector form.

Importance of Coulomb's law in vector form. Coulomb's law in vector form is more informative than in its scalar form for the following reasons :

1. In vector form, Coulomb's law straightway shows that the forces $\vec{F}_{12}$ and $\vec{F}_{21}$ are equal and opposite.

Since $\hat{r}_{12}$ and $\hat{r}_{21}$ are unit vectors pointing in opposite direction, we have

$$\hat{r}_{21} = -\hat{r}_{12}$$

Therefore, equation (1.11) becomes,

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} (-\hat{r}_{12}) = -\frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \hat{r}_{12} \qquad ...(1.13)$$

From equations (1.12) and (1.13), it follows that

$$\vec{F}_{12} = -\vec{F}_{21} \qquad ...(1.14)$$

Key point

From Coulomb's law in vector form, it follows that

(*i*) the two charges exert equal and opposite forces on each other.

(*ii*) the electrostatic force is central in nature.

2. From Coulomb's law in vector form, it follows that the electrostatic force between the two charges is a *central force i.e.* it acts along the line joining the two charges.

From equations (1.12) and (1.13), it follows that force experienced by one charge due to the other acts in the direction of unit vector $\hat{r}_{12}$ or in the direction opposite to that of $\hat{r}_{12}$. Since $\hat{r}_{12}$ is a unit vector along the line joining the two charges, the electrostatic force between two charges is a central force.

Note. In case the two charges are unlike, they will exert equal attractive forces on each other as shown in Fig. 1.03. Proceeding as above, it can be obtained that

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \hat{r}_{12}$$

and

$$\vec{F}_{21} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \hat{r}_{21}$$

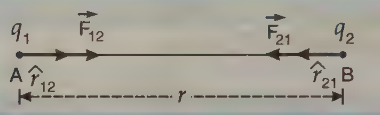

Fig. 1.03

1.13 FORCE BETWEEN TWO CHARGES IN TERMS OF THEIR POSITION VECTORS

To express force between two point charges in terms of their position vectors, consider a co-ordinate frame of reference OXYZ. Suppose that the two point charges q_1 and q_2 are present in space at the points A and B, whose position vectors are $\vec{OA} = \vec{r}_1$ and $\vec{OB} = \vec{r}_2$ as shown in Fig. 1.04. Join the two charges q_1 and q_2 by a straight line. If the distance between the two charges is denoted by r and $\hat{r}_{21}$ is unit vector from charge q_2 to q_1, then force on charge q_1 due to q_2 is given by

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \hat{r}_{21}$$

The above, equation can be rewritten as

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^3} (r\,\hat{r}_{21}) \qquad ...(1.15)$$

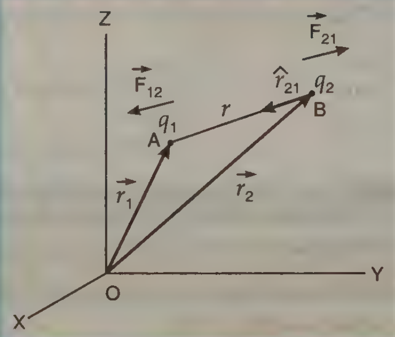

Fig. 1.04

From triangle law of addition of vectors, we have

$$\vec{OB} + \vec{BA} = \vec{OA} \qquad \text{or} \qquad \vec{BA} = \vec{OA} - \vec{OB}$$

or $$r\,\hat{r}_{21} = \vec{r}_1 - \vec{r}_2 \qquad (\because \vec{BA} = r\,\hat{r}_{21})$$

and $$r = |\vec{r}_1 - \vec{r}_2|$$

In equation (1.15), setting $r\,\hat{r}_{21} = \vec{r}_1 - \vec{r}_2$ and $r = |\vec{r}_1 - \vec{r}_2|$, we have

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{|\vec{r}_1 - \vec{r}_2|^3} (\vec{r}_1 - \vec{r}_2) \qquad \text{...(1.16)}$$

Similarly, it can be obtained that the force on charge q_2 due to q_1 is given by

$$\vec{F}_{21} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{|\vec{r}_2 - \vec{r}_1|^3} (\vec{r}_2 - \vec{r}_1) \qquad \text{...(1.17)}$$

1.14. PRINCIPLE OF SUPERPOSITION

Coulomb's law gives the force between two point electric charges. The principle of superposition gives a method to find force on a charge, when a group of charges are interacting.

The principle of superposition states that *when a number of charges are interacting, the total force on a given charge is the vector sum of the individual forces exerted on the given charge by all the other charges.*

The force between any two charges is not affected by the presence of other charges.

Key point ✓

The force between any two charges is not affected by the presence of other charges.

Consider that n point charges $q_1, q_2, q_3, \ldots q_n$ are distributed in space in a discrete manner. The charges are interacting with each other. Let us find the total force on charge say q_1 due to all other remaining charges. If the charges $q_2, q_3, \ldots q_n$ exert forces $\vec{F}_{12}, \vec{F}_{13}, \ldots \vec{F}_{1n}$ on the charge q_1 [Fig. 1.05], then according to principle of superposition, the total force on charge q_1 is given by

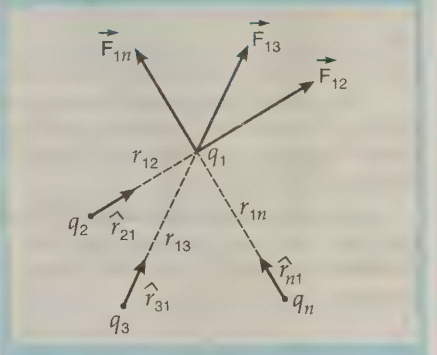

Fig. 1.05

$$\vec{F}_1 = \vec{F}_{12} + \vec{F}_{13} + \ldots\ldots + \vec{F}_{1n} \qquad \text{...(1.18)}$$

If the distance between the charges q_1 and q_2 is denoted as r_{12} ; and $\hat{r}_{21}$ is unit vector from charge q_2 to q_1, then

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r_{12}^2}\,\hat{r}_{21}$$

Similarly, the force on charge q_1 due to other charges is given by

$$\vec{F}_{13} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_3}{r_{13}^2}\,\hat{r}_{31}$$

....

....

and $$\vec{F}_{1n} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_n}{r_{1n}^2}\,\hat{r}_{n1}$$

Hence, in equation (1.18), substituting for $\vec{F}_{12}, \vec{F}_{13}, \ldots\ldots\ldots\ldots \vec{F}_{1n}$; the total force on charge q_1 due to all other charges is given by

$$\vec{F}_1 = \frac{1}{4\pi\varepsilon_0}\left(\frac{q_1 q_2}{r_{12}^2}\,\hat{r}_{21} + \frac{q_1 q_3}{r_{13}^2}\,\hat{r}_{31} + \ldots\ldots\ldots\ldots + \frac{q_1 q_n}{r_{1n}^2}\,\hat{r}_{n1}\right) \qquad \text{...(1.19)}$$

The same procedure can be adopted for finding the force on any other charge due to the remaining charges of the group of n charges. For example, force on charge q_2 due to all other charges is given by

$$\vec{F}_2 = \vec{F}_{21} + \vec{F}_{23} + \ldots\ldots + \vec{F}_{2n}$$

$$\vec{F}_2 = \frac{1}{4\pi\varepsilon_0}\left(\frac{q_2 q_1}{r_{21}^2}\,\hat{r}_{12} + \frac{q_2 q_3}{r_{23}^2}\,\hat{r}_{32} + \ldots\ldots\ldots\ldots + \frac{q_2 q_n}{r_{2n}^2}\,\hat{r}_{n2}\right)$$

Superposition principle in terms of position vectors of the charges. Suppose that the point charges $q_1, q_2, q_3, \ldots\ldots q_n$ are located at points in space, whose position vectors are $\vec{r}_1, \vec{r}_2, \vec{r}_3, \ldots\ldots \vec{r}_n$ respectively. Let $\hat{r}_{21}, \hat{r}_{31}, \ldots\ldots \hat{r}_{n1}$ be unit vectors from charge q_2 to q_1, from q_3 to q_1, ... from q_n to q_1 as shown in Fig. 1.06. Then, by proceeding as in section 1.13, the force on charge q_1 due to q_2 is given by

$$\vec{F}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{|\vec{r}_1 - \vec{r}_2|^3} (\vec{r}_1 - \vec{r}_2)$$

Similarly, force on charge q_1 due to q_3

$$\vec{F}_{13} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_3}{|\vec{r}_1 - \vec{r}_3|^3} (\vec{r}_1 - \vec{r}_3)$$

....

....

and
$$\vec{F}_{1n} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{|\vec{r}_1 - \vec{r}_n|^3} (\vec{r}_1 - \vec{r}_n)$$

Therefore, total force on charge q_1 due to all other charges is given by

$$\vec{F}_1 = \frac{1}{4\pi\varepsilon_0} \left(\frac{q_1 q_2}{|\vec{r}_1 - \vec{r}_2|^3} (\vec{r}_1 - \vec{r}_2) + \frac{q_1 q_3}{|\vec{r}_1 - \vec{r}_3|^3} (\vec{r}_1 - \vec{r}_3) + ... + \frac{q_1 q_n}{|\vec{r}_1 - \vec{r}_n|^3} (\vec{r}_1 - \vec{r}_n) \right) \quad ...(1.20)$$

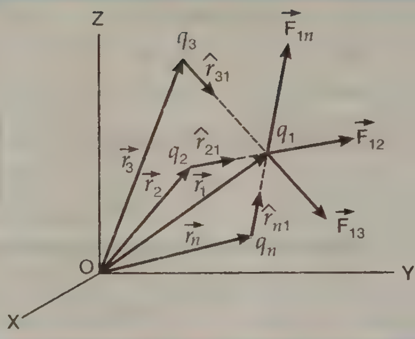

Fig. 1.06

1.15. CONTINUOUS DISTRIBUTION OF CHARGE

As said earlier, the electric charge is quantized and the charge on a charged body is always an integral multiple of the charge on a single electron or a proton. In most of the practical situations, charge on a charged body is so large as compared to the magnitude of charge on an electron or a proton that the quantization of charge may be ignored. In other words, we can assume that on a charged body of reasonable size, charge has continuous distribution.

The continuous distribution of charge may be one dimensional, two dimensional or three dimensional. Accordingly, the distribution of charge is called ***linear charge distribution, surface charge distribution*** and ***volume charge distribution*** respectively.

1. Linear charge density. When charge is distributed along a line (straight or curved), the charge distribution is called linear. Fig. 1.07 shows the uniform distribution of charge q over the length L of a straight rod. Then, linear charge density is defined as

$$\lambda = \frac{q}{L}$$

Its unit is **coulomb metre^{-1} (C m^{-1}).**

For example, if charge q is uniformly distributed over a circular ring of radius R, then its linear charge density is $\frac{q}{2\pi R}$.

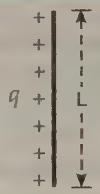

Fig. 1.07

2. Surface charge density. When charge is distributed over a surface (plane or curved), the charge distribution is called surface charge distribution. Fig. 1.08 shows the uniform distribution of charge q over a plane surface of area A. Then, surface charge distribution is defined as

$$\sigma = \frac{q}{A}$$

Its unit is **coulomb metre^{-2} (C m^{-2}).**

For example, if charge q is uniformly distributed over the surface of a spherical conductor of radius R, then its surface charge density is $\frac{q}{4\pi R^2}$.

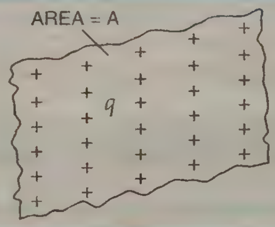

Fig. 1.08

3. Volume charge density. When charge is distributed over the volume of an object, it is called volume charge distribution. Fig. 1.09 shows the uniform distribution of charge q over the volume V of a spherical object. Then, volume charge density is defined as

$$\rho = \frac{q}{V}$$

Its unit is **coulomb metre^{-3} (C m^{-3}).**

For example, if charge q is uniformly distributed over the entire volume of a sphere, then its volume charge density is $\frac{q}{\frac{4}{3}\pi R^3}$.

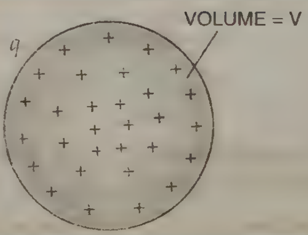

Fig. 1.09

1.16. FORCE DUE TO A CONTINUOUS DISTRIBUTION OF CHARGES

Now, we calculate the force experienced by a charge q_0 due to a continuous charge distribution in the following cases :

1. When charge is distributed continuously along a line. Consider a line charge L (straight or curved) having a uniform continuous distribution of charge along its length. Suppose that we have to find force due to the line charge on a point charge q_0 placed at a point, whose position vector is $\vec{r}$ [Fig. 1.10].

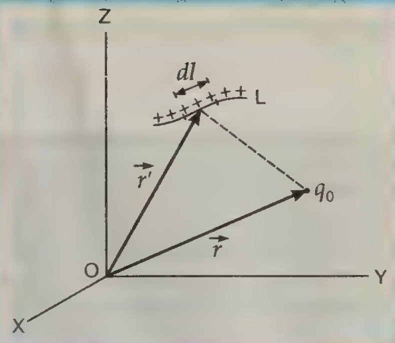

Fig. 1.10

Let *dl* be an infinitesimally small length of the line charge L. If λ is linear charge density of the line L charge, then charge on the length element *dl* is given by

$$dq = \lambda \, dl$$

Let $\vec{r}'$ be position vector of this elementary portion of the line charge having charge *dq*.

Then, force on charge q_0 due to charge *dq* (= λ *dl*) on length element *dl* is given by

$$d\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_0 \cdot dq}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}')$$

Substituting for *dq*, we have

$$d\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_0 \, \lambda \, dl}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}')$$

The force on charge q_0 due to the whole line charge distribution can be found by integrating the above over its total length *i.e.*

$$\vec{F} = \int_L \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_0 \, \lambda \, dl}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}')$$

or

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot q_0 \int_L \frac{\lambda \, dl}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \qquad \text{...(1.21)}$$

2. When charge is distributed continuously over a surface. Consider a surface S having a uniform continuous distribution of charge along its surface. Suppose that we have to find force due to surface charge S on a point charge q_0 placed at a point, whose position vector is $\vec{r}$ [Fig. 1.11].

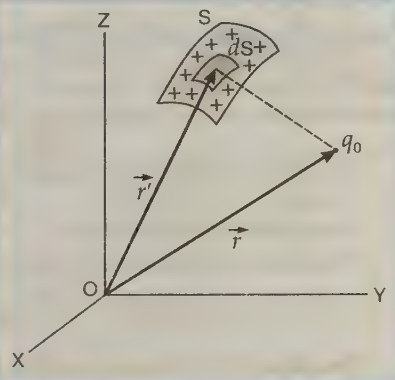

Fig. 1.11

Let *d*S be an infinitesimally small area of the surface charge S. If σ is surface charge density of surface S, then charge on the surface element *d*S is given by

$$dq = \sigma \, dS$$

Let $\vec{r}'$ be position vector of this elementary portion of the surface charge having charge *dq*.

Then, force on charge q_0 due to charge *dq* (= σ *d*S) on the surface element *d*S is given by

$$d\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_0 \, \sigma \, dS}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}')$$

The force on charge q_0 due to whole surface charge distribution can be found by integrating the above over its total surface area *i.e.*

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot q_0 \int_S \frac{\sigma \, dl}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \qquad \text{...(1.22)}$$

3. When charge is distributed continuously over a volume. Consider a volume V having a uniform continuous distribution of charge. Suppose that we have to find force due to volume charge V on a point charge placed at a point, whose position vector is $\vec{r}$ [Fig. 1.12].

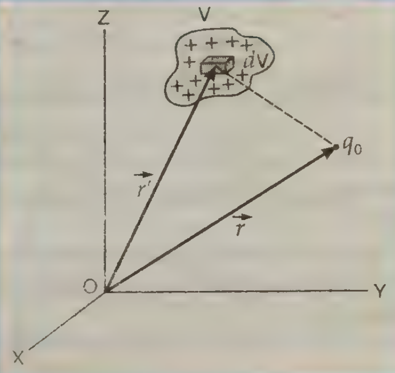

Fig. 1.12

Let *d*V be an infinitesimally small volume of the volume charge V. If ρ is volume charge density of volume V, then charge on the volume element *d*V is given by

$$dq = \rho \, dV$$

Let $\vec{r}'$ be position vector of this elementary portion of the volume charge having charge *dq*.

The force on the charge q_0 due to the charge dq $(= \rho\, dV)$ on the volume element dV is given by

$$\overrightarrow{dF} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_0\, \rho\, dV}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}')$$

The force on charge q_0 due to whole volume charge distribution can be found by integrating the above over its total volume *i.e.*

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot q_0 \int_V \frac{\rho\, dV}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \qquad \text{...(1.23)}$$

Note. 1. In case charges are distributed in a discrete manner, the force on a charge due to the discrete distribution of charges is found by adding the forces exerted by the individual charges. Accordingly, the summation sign is used to add such forces. However, when charges are distributed in a continuous manner, the effect can only be summed up by the method of integration.

2. If charge is distributed continuously over a line L, over a surface S, over a volume V and also in a discrete manner in the space, then total force on charge q_0 at location $\vec{r}$ will be

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot q_0 \left(\int_L \frac{\lambda\, dl}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') + \int_S \frac{\sigma\, dS}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') + \int_V \frac{\rho\, dV}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') + \sum_{\substack{\text{all} \\ \text{points charges}}} \frac{q'}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \right) \qquad \text{...(1.24)}$$

In equation (1.24), $\vec{r}'$ has been used to denote the position vector of elementary ortion of line charge L, surface charge S, volume charge V and any one charge q' f the discrete distribution of charges in space.

SOLVED NUMERICAL PROBLEMS

Type A. On Quantization of Charge

Problem 1.01. A polythene piece rubbed with wool is found to have a negative charge of 3×10^{-7} C. Estimate the number of electrons transferred from wool to polythene. *(C.B.S.E. 1990 ; Text Problem)*

Sol. Here, total charge transferred, $q = -3 \times 10^{-7}$ C

Charge on an electron, $e = -1 \cdot 6 \times 10^{-19}$ C

From quantization of charge, $q = n\, e$

Therefore, number of electrons transferred,

$$n = \frac{q}{e} = \frac{-3 \times 10^{-7}}{-1 \cdot 6 \times 10^{-19}} = \mathbf{1 \cdot 875 \times 10^{12}}$$

Problem 1.02. Calculate the total positive or negative charge on a $3 \cdot 11$ g copper penny. Given Avogadro number $= 6 \cdot 02 \times 10^{23}$, atomic number of copper = 29 and atomic mass of copper = $63 \cdot 5$.

Sol. Here, mass of copper penny, $m = 3 \cdot 11$ g

$Z = 29$; $A = 63 \cdot 5$ and $N = 6 \cdot 02 \times 10^{23}$

Number of atoms in the copper penny, $n = \frac{N}{A} \times m$

or $$n = \frac{6 \cdot 02 \times 10^{23} \times 3 \cdot 11}{63 \cdot 5} = 2 \cdot 95 \times 10^{22}$$

Number of protons or electrons in the copper penny

$= n \times Z$

$= 2 \cdot 95 \times 10^{22} \times 29$

Therefore, total positive or negative charge in the copper penny,

$q = 2 \cdot 95 \times 10^{22} \times 29 \times 1 \cdot 6 \times 10^{-19}$

$= \mathbf{1 \cdot 37 \times 10^5}$ **C**

Type B. On Coulomb's law in electrostatics

Problem 1.03. What is the force between two sma charged spheres having charges of 2×10^{-7} C and 3×10^{-7} placed 30 cm in air ? *(Text Probler*

Sol. Here, $q_1 = 2 \times 10^{-7}$ C ; $q_2 = 3 \times 10^{-7}$ C;

$r = 30$ cm $= 0 \cdot 3$ m

In air, $F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}$

$= 9 \times 10^9 \times \frac{(2 \times 10^{-7}) \times (3 \times 10^{-7})}{(0 \cdot 3)^2}$

$= \mathbf{6 \times 10^{-3}}$ **N (repulsive)**

Problem 1.04. The electrostatic force of repulsic between two equal positively charged ions is $3 \cdot 7 \times 10^{-9}$ I when they are separated by a distance of 5 Å. How mar electrons are missing from each other ? *(C.B.S.E. 200*

Sol. Here, $F = 3 \cdot 7 \times 10^{-9}$ N ; $r = 5$ Å $= 5 \times 10^{-10}$ m

Suppose that n electrons have been removed to for each positive ion. Then, charge on each positive ion,

$q_1 = q_2 = n \times 1 \cdot 6 \times 10^{-19}$ C

Now, $F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}$

$\therefore\ 3 \cdot 7 \times 10^{-9} = \frac{9 \times 10^9 \times (n \times 1 \cdot 6 \times 10^{-19})^2}{(5 \times 10^{-10})^2}$

or $n = \mathbf{2}$

**Problem 1.05. The electrostatic force on a small sphe of charge $0 \cdot 4\ \mu$C due to another small sphere of charg $-0 \cdot 8\ \mu$C in air is 0·2 N. (*a*) What is the distance betwe

the two spheres ? (b) What is the force on the second sphere due to the first ? (*Text Problem*)

Sol. Here, $q_1 = 0 \cdot 4\ \mu C = 0 \cdot 4 \times 10^{-6}\ C$;

$q_2 = -0 \cdot 8\ \mu C = -0 \cdot 8 \times 10^{-6}\ C$

(*a*) Force on charge q_1 due to q_2, $F_{12} = 0 \cdot 2\ N$

In air, $F_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} = 9 \times 10^9 \times \frac{q_1 q_2}{r^2}$

or $0.2 = 9 \times 10^9 \times \frac{(0 \cdot 4 \times 10^{-6}) \times (0 \cdot 8 \times 10^{-6})}{r^2}$

or $r = \mathbf{0 \cdot 12\ m}$

(*b*) Force on charge q_2 due to q_1,

$F_{21} = F_{12} = \mathbf{0 \cdot 2\ N}$ **(attractive)**

Problem 1.06. A free pith-ball of 8 g carries a positive charge of 5 × 10⁻⁸ C. What must ball be nature and magnitude of charge that should be given to a second pith-ball fixed 5 cm vertically below the former pith ball so that the upper pith ball is stationary ? (*H.S.S.C.E. 2001*)

Sol. Here, charge on pith-ball A, $q_1 = 5 \times 10^{-8}\ C$

mass of pith-ball A, $m_1 = 8\ g = 8 \times 10^{-3}\ kg$

The weight $m_1 g$ of the pith-ball A acts vertically downwards.

Let q_2 be charge on the pith-ball B held 5 cm below the pith-ball A, so that the pith-ball A remains stationary. It can be possible only, if the charges on two pith-balls are of same signs *i.e.* if charge on pith-ball A is positive, charge on B should also be **positive.** Then, the force on pith-ball A due to B *i.e.* F_{AB} will act vertically upwards [Fig. 1.13].

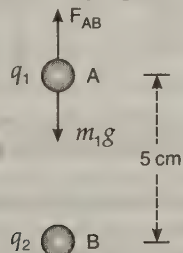

Fig. 1.13.

For charge q_1 to remain stationary,

$$F_{AB} = m_1 g$$

or $\frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{AB^2} = m_1 g$

Here, $AB = 5\ cm = 0 \cdot 05\ m$

$\therefore\ 9 \times 10^9 \times \frac{5 \times 10^{-8} \times q_2}{(0 \cdot 05)^2} = 8 \times 10^{-3} \times 9 \cdot 8$

or $q_2 = \mathbf{4 \cdot 36 \times 10^{-7}\ C}$ **(positive)**

Problem 1.07. (a) Two insulated charged copper, spheres A and B have their centres separated by a distance of 50 cm. What is the mutual force of electrostatic repulsion, if charge on each is 6 · 5 × 10⁻⁷ C ? The radii of A and B are negligible as compared to the distance of separation.

(b) What is the force of repulsion, if (i) each sphere is charged to double the above amount and the distance between them is halved, (ii) the two spheres are placed in water ? (Dielectric constant of water = 80). (*Text Problem*)

Sol. (*a*) Here, charge on sphere A, $q_1 = 6 \cdot 5 \times 10^{-7}\ C$

Charge on sphere B, $q_2 = 6 \cdot 5 \times 10^{-7}\ C$

Distance between the spheres A and B,

$r = 50\ cm = 0 \cdot 5\ m$

Now, $F_{air} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} = 9 \times 10^9 \times \frac{(6 \cdot 5 \times 10^{-7})^2}{(0 \cdot 5)^2}$

$= \mathbf{1 \cdot 521 \times 10^{-2}\ N}$

***(b) (i) When each sphere is charged to double the amount*:**

Here, $q_1 = q_2 = 2 \times 6 \cdot 5 \times 10^{-7}\ C$; $r = \frac{0 \cdot 5}{2} = 0 \cdot 25\ m$

Now, $F_{air} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}$

$= 9 \times 10^9 \times \frac{(2 \times 6 \cdot 5 \times 10^{-7})^2}{(0 \cdot 25)^2} = \mathbf{0 \cdot 2434\ N}$

***(ii) When charges are placed in water* :**

$F_{water} = \frac{1}{4\pi\varepsilon_0 K} \cdot \frac{q_1 q_2}{r^2} = \frac{F_{air}}{K}$

Here, $K = 80$

$\therefore\ F_{water} = \frac{1 \cdot 521 \times 10^{-2}}{80} = \mathbf{1 \cdot 9 \times 10^{-4}\ N}$

Problem 1.08. Suppose in the problem 1.07 (a), the spheres A and B have identical sizes. A third sphere of the same size but uncharged is brought in contact with the first, then brought in contact with the second and finally removed from both. What is the new force of repulsion between A and B ? (*Text Problem*)

Sol. Original charge on sphere A or B,

$q_1 = q_2 = 6 \cdot 5 \times 10^{-7}\ C$

Distance between the two spheres, $r = 0{\cdot}05\ m$

Since all the spheres are of same size, they will possess equal charges on being brought in contact.

When uncharged sphere C ($q_3 = 0$) is brought in contact with A, charge left on sphere A,

$q_1' = \frac{q_1 + q_3}{2} = \frac{6 \cdot 5 \times 10^{-7} + 0}{2} = 3 \cdot 25 \times 10^{-7}\ C$

and charge on sphere C, $q_3' = 3 \cdot 25 \times 10^{-7}\ C$

Therefore, when sphere C is brought in contact with B, charge left on sphere B,

$q_2' = \frac{q_2 + q_3'}{2} = \frac{6 \cdot 5 \times 10^{-7} + 3 \cdot 25 \times 10^{-7}}{2}$

$= 4 \cdot 875 \times 10^{-7}\ C$

Therefore, new force of repulsion between spheres A and B,

$F_{air} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1' q_2'}{3}$

$= 9 \times 10^9 \times \frac{3 \cdot 25 \times 10^{-7} \times 4 \cdot 875 \times 10^{-7}}{(0 \cdot 5)^2}$

$= \mathbf{5 \cdot 704 \times 10^{-3}\ N}$

Problem 1.09. Two point charges of charge values Q and *q* are placed at a distance of *x* and *x*/2 respectively from a third charge of charge value 4 *q*, all charges being in the same straight line. Calculate the magnitude and nature of charge Q, such that the net force experienced by the charge *q* is zero. (*C.B.S.E. 1998*)

Sol. Suppose that the charge 4 *q* is located at point A. The charges Q and *q* are placed at points B and C, such that AB = *x* and AC = *x*/2. Also, all the charges lie on the same straight line [Fig. 1.14]. We assume that charges of 4 *q* and *q* are of same nature, say positive.

Then, force on charge *q* due to 4 *q*,

$$F_A = \frac{1}{4\pi\varepsilon_0}\cdot\frac{4q.q}{(x/2)^2} \qquad \text{(along CB)}$$

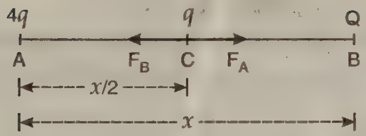

Fig. 1.14.

The net force experienced by charge q will be zero only if charge Q exerts force on charge q equal and opposite to that exerted by charge 4 q. Thus, charge Q should exert force F_B on charge q equal to F_A (in magnitude) and along CA. For this, charge Q has to be **positive** (*i.e* of the nature, same as that of 4 q or q).

Now, force on charge q due to charge Q,

$$F_B = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Q.q}{(BC)^2}$$

or $$F_B = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Q.q}{(x/2)^2} \qquad \text{(along CA)}$$

For net force on charge q to be zero, $F_B = F_A$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{Q.q}{(x/2)^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{4q.q}{(x/2)^2}$$

or $$Q = 4q$$

Problem 1.10. Two pith-balls each weighing 10^{-3} kg are suspended from the same point by means of silk threads 0·5 long. On charging the pith-balls equally, they are found to repel each other to a distance of 0·2 m. Calculate the charge on each ball. (*H.S.S.C.E. 2002*)

Sol. Consider two pith-balls A and B each having charge q and mass 10^{-3} kg.

When the pith-balls are suspended from point S by two threads each 0 · 5 m long, they repel each other to distance AB = 0·2 m as shown in Fig. 1.15.

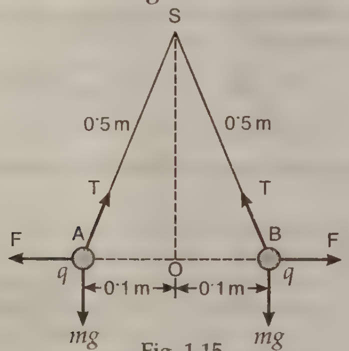

Fig. 1.15

Each of the two pith-balls is in equilibrium under action of the following three forces :

(*i*) The electrostatic repulsive force F.

(*ii*) The weight mg acting vertically downwards.

(*iii*) The tension T in the string directed towards point S.

The three forces mg, F and T can be represented by the three sides, SO, OA and AS of the Δ AOS taken in order. Therefore, according to triangle law of forces,

$$\frac{F}{OA} = \frac{mg}{SO} = \frac{T}{AS} \qquad \text{...}(i)$$

Here, $F = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{(AB)^2} = 9\times10^9\times\frac{q^2}{(0\cdot2)^2}$ N,

$mg = 10^{-3}\times9\cdot8 = 9\cdot8\times10^{-3}$ N

From equation (*i*), we have

$$F = mg\times\frac{OA}{SO}$$

or $$9\times10^9\times\frac{q^2}{(0\cdot2)^2} = 9\cdot8\times10^{-3}\times\frac{0\cdot1}{\sqrt{(0\cdot5)^2-(0\cdot1)}}$$

or $$q = 2\cdot357\times10^{-6}\text{ C}$$

Problem 1.11. Two small spheres each having ma m kg and charge q coulomb are suspended from a point insulating threads each l metre long but of negligible ma If θ is the angle, each string makes with the vertical wh equilibrium has been attained, show that

$$q^2 = (4\,m\,g\,l^2\sin^2\theta\tan\theta)\,4\pi\varepsilon_0 \qquad \text{(P.S.S.C.E. 199}$$

Sol. Consider two small spheres A and B each of ma m kg and charge q coulomb. When the two spheres a suspended from point S by two threads each of length l, th repel each other and when equilibrium is attained, each stri makes an angle θ with the vertical [Fig. 1.16].

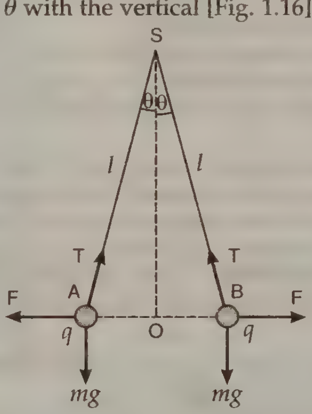

Fig. 1.16

Each of the two spheres is acted upon by the followi three forces :

(*i*) The electrostatic force of repulsion F directed aw from each other.

(*ii*) The weight mg of the sphere acting vertica downwards.

(*iii*) The tension T in the string directed towards poin

Since the two spheres are in equilibrium, the three for acting on a sphere can be represented by the three sides of Δ AOS taken in order. For sphere A, we have

$$\frac{F}{OA} = \frac{mg}{SO} = \frac{T}{AS}$$

Here, OA = $l\sin\theta$; SO = $l\cos\theta$

and AB = 2 AO = $2\,l\sin\theta$

and $$F = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q\times q}{AB^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{4l^2\sin^2\theta}$$

From equation (*i*), we have

$$F = mg\times\frac{OA}{SO}$$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{4l^2\sin\theta} = mg\times\frac{l\sin\theta}{l\cos\theta}$$

or $$q^2 = (4\,m\,g\,l^2\sin^2\theta\tan\theta)\,4\pi\varepsilon_0$$

Type C. On Superposition Principle

Problem 1.12. Three charges 10 μC, 5 μC and – 5 μC a plaed in air at the three corners A, B and C of an equilate triangle of side 0 · 1 m. Find the resultant force experienc by charge placed at corner A.

Sol. Here, $q_A = 10\ \mu C = 10^{-5}\ C$; $q_B = 5 \times 10^{-6}\ C$;
$q_C = -5 \times 10^{-6}\ C$ and $AB = BC = AC = 0 \cdot 1$ m

$$\text{Now, } F_{AB} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A q_B}{AB^2} = \frac{9 \times 10^9 \times 10^{-5} \times 5 \times 10^{-6}}{(0 \cdot 1)^2}$$

$$\text{or} \quad F_{AB} = 45\ N \quad \text{(repulsive)}$$

$$\text{Also, } F_{AC} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A q_C}{AC^2} = \frac{9 \times 10^9 \times 10^{-5} \times 5 \times 10^{-6}}{(0 \cdot 1)^2}$$

$$\text{or} \quad F_{AC} = 45\ N \quad \text{(attractive)}$$

The forces F_{AB} and F_{AC} are inclined at an angle of 120° as shown in Fig. 1.17.

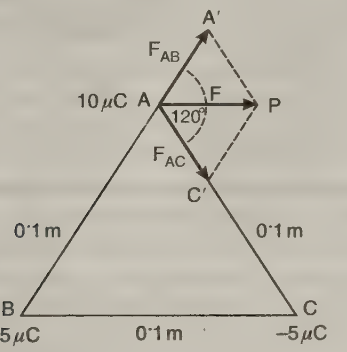

Fig. 1.17

If F is the resultant force on charge q_A, then

$$F = \sqrt{F_{AB}^2 + F_{AC}^2 + 2\, F_{AB} \cdot F_{AC} \cos 120°}$$
$$= \sqrt{45^2 + 45^2 + 2 \times 45 \times 45 \times (-0 \cdot 5)}$$
$$= 45\sqrt{1 + 1 - 1} = \mathbf{45\ N}$$

The resultant force acts on charge 10 μC charge along AP *i.e.* **parallel to side BC of the Δ ABC.**

Problem 1.13. ABC is an equilateral triangle of side 10 m and D is the middle point of BC. Charges of +100, – 100 and + 75 coulomb are placed at B, C and D respectively. What is the force experienced by 1 coulomb positive charge placed at A ?

Sol. Consider an equilateral Δ ABC of each side 10 m. The point D is middle point of side BC. The charges $q_B = +100$ C, $q_C = -100$ C and $q_D = +75$ C are placed at the points B, C and D and a charge $q_A = 1$ C is placed at point A [Fig. 1.18].

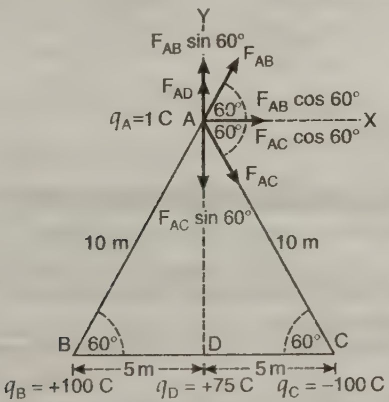

Fig. 1.18

Due to the charges q_B, q_C and q_D, the charge q_A experiences forces F_{AB}, F_{AC} and F_{AD} in the directions as shown in the figure.

$$\text{Now, } F_{AB} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A q_B}{AB^2} = 9 \times 10^9 \times \frac{1 \times 100}{10^2}$$
$$= 9 \times 10^9\ N \quad \text{(along BA)}$$

$$F_{AC} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A q_C}{AC^2} = 9 \times 10^9 \times \frac{1 \times 100}{10^2}$$
$$= 9 \times 10^9\ N \quad \text{(along AC)}$$

$$F_{AC} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A q_D}{AC^2} = 9 \times 10^9 \times \frac{1 \times 75}{(10^2 - 5^2)}$$
$$= 9 \times 10^9\ N \quad \text{(along DA)}$$

To find the resultant force on charge q_A, through point A, draw a line AX parallel to side BC as X-axis. Let us regard the line DA, the right bisector of line BC as Y-axis.

Resolve both the forces F_{AB} and F_{AC} into components along X-axis and Y-axis as shown in Fig. 1.18. Then, total force on charge q_A along X-axis,

$$F_x = F_{AB} \cos 60° + F_{AC} \cos 60°$$
$$= 9 \times 10^9 \times 0 \cdot 5 + 9 \times 10^9 \times 0 \cdot 5 = 9 \times 10^9\ N$$

The components $F_{AB} \sin 60°$ and $F_{AC} \sin 60°$ being equal and opposite, just cancel each other. Therefore,

force on charge q_A along Y-axis, ,

$$F_y = F_{AD} = 9 \times 10^9\ N$$

The two forces F_x and F_y acting on the charge q_A have been represented separately in Fig. 1.19.

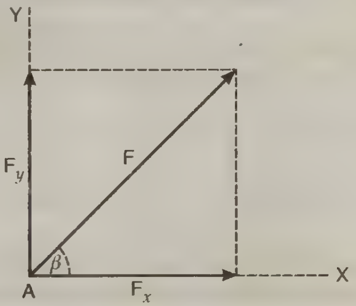

Fig. 1.19

If F is the resultant force on charge q_A, then

$$F = \sqrt{F_x^{\,2} + F_y^{\,2}} = \sqrt{(9 \times 10^9)^2 + (9 \times 10^9)^2}$$
$$= \mathbf{9\sqrt{2} \times 10^9\ N}$$

If the resultant force makes an angle β with X-axis, then

$$\tan\beta = \frac{F_y}{F_x} = \frac{9 \times 10^9}{9 \times 10^9} = 1 \quad \text{or} \quad \boldsymbol{\beta = 45°}$$

i.e. the resultant force on charge q_A is inclined at 45° with X-axis *i.e.* with the side BC of the triangle.

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 1.14. Two charges each of + Q units are placed along a line. A third charge – *q* is placed between them. At what position and for what value of *q*, will the system be in equilibrium ?

Sol. Let the two charges + Q each be placed at points A and B at a distance *r* between them and charge – *q* be placed at point O, such that AO = x and OB = $r-x$ [Fig. 1.20].

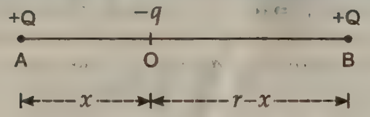

Fig. 1.20

The system will be in equilibrium, if charge $-q$ as well as either of the two charges $+Q$ each placed at points A and B experience *zero* net force.

(i) For charge − q to be in equilibrium : For this, force on charge $-q$ at point O due to charge $+Q$ at point A should be equal and opposite to that due to charge $+Q$ at point B *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{x^2}=\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{(r-x)^2}$$

$$\text{or}\quad x^2=(r-x)^2\quad\text{or}\quad x=\pm(r-x)\quad\text{or}\quad x=\frac{r}{2}$$

(ii) For charge + Q at A (or at B) to be in equilibrium : For this, force on charge $+Q$ at point A due to charge $-q$ at O should be equal and opposite to that due to charge $+Q$ at B *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{(r/2)^2}=\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{r^2}\quad\text{or}\quad q=\frac{Q}{4}$$

Therefore, the system of three charges will be in equilibrium, if charge $-q$ is equal to $-\frac{Q}{4}$ and is placed at the **mid-point** of the distance between the two charges of $+Q$ each.

Problem 1.15. Two identical point charges of charge Q are kept at a distance *r* from each other. A third point charge is placed on the line joining the above two charges, such that all the three charges are in equilibrium. Calculate the magnitude and location of the third charge.

(C.B.S.E. 1998)

Ans. Let the two charges of $+Q$ each be placed at points A and B at a distance r apart as shown in Fig. 1.21.

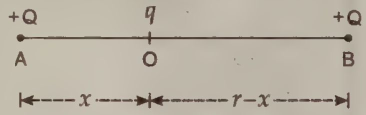

Fig. 1.21

Suppose that the third charge q (in magnitude) is placed at point O on the line joining the other two charges, such that AO = x and OB = $r-x$. For the system of the three charges to be in equilibrium, net force on each of the three charges must be zero.

At first instance, if we assume that charge q placed a point O is positive in nature, then it will experience forces du to other two charges in opposite directions and hence ne forces on the charge q may be zero. But as such (when q i taken positive), the force on the charge Q at point A or at poin B will not be zero. It is because, the forces on a charge Q du to the other two charges will act in same direction. Howeve if the charge q placed at point O is taken negative, then on charge Q, forces due to the other two charges will act i opposite directions. Hence, the third charge q placed at poin O must be **negative** in nature.

(i) For charge − q to be in equilibrium : For this, force o charge $-q$ at point O due to charge $+Q$ at point A should b equal and opposite to that due to charge $+Q$ at point B *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{x^2}=\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{(r-x)^2}$$

$$\text{or}\quad x^2=(r-x)\quad\text{or}\quad x=\pm(r-x)\quad\text{or}\quad x=\frac{r}{2}$$

(ii) For charge + Q at A (or at B) to be in equilibrium : Fo this, force on charge $+Q$ at point A due to charge $-q$ at O shoul be equal and opposite to that due to charge $+Q$ at B *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{(r/2)^2}=\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{r^2}\quad\text{or}\quad q=\frac{Q}{4}$$

Therefore, the system of three charges will be i equilibrium, if charge $-q$ is equal to $-\frac{Q}{4}$ and is placed at th **mid-point** of the distance between the two charges of + each.

Problem 1.16. A charge having magnitude Q is divide into two parts *q* and (Q − *q*). If the two parts exert maximum force of repulsion on each other, then find th ratio Q/*q*.

Sol. Suppose that the parts q and $(Q-q)$ are placed at distance r apart. Then,

$$F=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q(Q-q)}{r^2}$$

Now, for force F to be maximum, $\frac{\partial F}{\partial q}=0$

$$i.e.\qquad \frac{\partial}{\partial q}\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{q(Q-q)}{r^2}\right)=0$$

$$\text{or}\qquad \frac{\partial}{\partial q}[q(Q-q)]=0$$

$$\text{or}\quad 1(Q-q)+q(0-1)=0\quad\text{or}\quad Q-2q=0\quad\text{or}\quad \frac{Q}{q}=2$$

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 1.01. What kind of charges are produced on each, when (*i*) a glass rod is rubbed with silk and (*ii*) an ebonite rod is rubbed with wool ? *(C.B.S.E. 1990)*

Ans. (*i*) On glass rod : positive charge and
on silk : negative charge
(*ii*) On ebonite rod : negative charge and
on wool : positive charge.

Q. 1.02. An ebonite rod held in hand can be charged by rubbing with flannel but a copper rod cannot be charged like this. Why ? *(H.P.S.S.C.E. 1997)*

Ans. Both the human body and the copper rod conduct electricity. When it is attempted to charge a metal rod by rubbing, the charge flows from the rod to the earth through the hand. However, when ebonite rod is charged by rubbin the charges so produced stay on the ebonite rod, as it is ba conductor of electricity.

Q. 1.03. What does $q_1+q_2=0$ signify in electrostatics ? *(C.B.S.E. 2001 S*

Ans. The charges q_1 and q_2 are equal and opposite.

Q. 1.04. When a polythene piece is rubbed with woo it acquires negative charge. Is there a transfer of mass fro wool to polythene ?

Ans. The polythene piece acquires negative charge du to transfer of electrons from wool to it. Since electrons a material particles, there is a transfer of mass from wool t polythene.

Q. 1.05. A glass rod, when rubbed with silk cloth, acquires a charge $1 \cdot 6 \times 10^{-13}$ coulomb. What is the charge on the silk cloth ? *(H.P.S.S.C.E. 1999 ; H.S.S.C.E. 1999)*

Ans. Silk cloth will also acquire a charge $1 \cdot 6 \times 10^{-13}$ coulomb. However, it will be negative in nature.

Q. 1.06. How much is the charge on an electron in SI units ? *(H.S.S.C.E. 1996)*

Ans. In SI, charge on electron is $1 \cdot 6 \times 10^{-19}$ C (negative).

Q. 1.07. What is the least possible value of charge ? *(H.S.S.C.E. 2002)*

Ans. A positively charged particle can possess positive charge equal to the charge on a proton ($+ 1 \cdot 6 \times 10^{-19}$ C) and a negatively charged particle equal to the charge on an electron ($- 1 \cdot 6 \times 10^{-19}$ C). A particle can not have a fractional part of this elementary amount of charge *i.e.* $1 \cdot 6 \times 10^{-19}$ C.

Q. 1.08. Can a body have a charge of $0 \cdot 8 \times 10^{-19}$ C ? Justify your answer by comment ? *(H.P.S.S.C.E. 1999 S)*

Ans. No. For details, refer to VSQ 1.07.

Q. 1.09. What is meant by quantization of charge ? *(P.S.S.C.E. 2000 ; H.S.S.C.E. 1999 S)*

Ans. Refer to section 1.06.

Q. 1.10. Name the experiment, which established quantum nature of electric charge. *(C.B.S.E. 1998)*

Ans. Millikan's oil drop experiment for measuring charge on an electron.

Q. 1.11. State two properties of electric charge. *(P.S.S.C.E. 1998 S)*

Ans. 1. Electric charge is quantized. **2.** Electric charge is always conserved in a physical process.

Q. 1.12. Given two point charges q_1 and q_2, such that $q_1 q_2 < 0$. What is the nature of force between them ? *(H.P.S.S.C.E. 2002)*

Ans. When $q_1 q_2 < 0$, it implies that if one charge is positive, the other must be negative. Hence, when $q_1 q_2 < 0$, the force between the two charges will be attractive in nature.

Q. 1.13. State Coulomb's law in electrostatics. *(C.B.S.E. 1994 ; I.S.C.E. 1993)*

Ans. Refer to section 1.09.

Q. 1.14. Give mathematical expression for Coulomb's law for electric charges. *(H.S.S.C.E. 2002)*

Ans. $F = \dfrac{1}{4\pi\varepsilon_0} \cdot \dfrac{q_1 q_2}{r^2}$

Q. 1.15. Give the unit of electrical permittivity of free space. *(H.S.S.C.E. 2002)*

Ans. $C^2 N^{-1} m^{-2}$.

Q. 1.16. Write down the value of absolute permittivity of free space (vacuum). *(P.S.S.C.E. 1996)*

Ans. $\varepsilon_0 = 8 \cdot 854 \times 10^{-12} C^2 N^{-1} m^{-2}$.

Q. 1.17. What is the value of constant of proportionality $\dfrac{1}{4\pi\varepsilon_0}$ involved in expression for Coulomb's force between two charges ?

Ans.
$$\frac{1}{4\pi\varepsilon_0} = \frac{1}{4\pi \times 8 \cdot 854 \times 10^{-12} C^2 N^{-1} m^{-2}}$$
$$= 9 \times 10^9 \text{ N m}^2 \text{C}^{-2}$$

Q. 1.18. In the relation $F = k \dfrac{q_1 q_2}{r^2}$, what is the value of k in free space ? *(H.S.S.C.E. 2002)*

Ans. In SI, the value of constant k is 9×10^9 N m² C⁻².

Q. 1.19. Electrostatic force between two charges is called central force. Why ?

Ans. The force between two electric charges always acts along the line joining the two charges. For this reason, it is called central force.

Q. 1.20. Define coulomb as a unit of charge. *(P.S.S.C.E. 2002 ; H.P.S.S.C.E. 1999)*

Or

Define the unit of electric charge. *(P.S.S.C.E. 2000, 1999)*

Ans. Refer to section 1.10.

Q. 1.21. In Coulomb's law, on what factors the value of electrostatic force constant k depends ? *(H.P.S.S.C.E. 2002)*

Ans. On the system of units adopted and the nature of medium, in which two charges are placed.

Q. 1.22. Define dielectric constant of a medium. *(P.S.S.C.E. 2000, 1999 ; H.S.S.C.E. 1995)*

Ans. Refer to section 1.11.

Q. 1.23. Dielectric constant of water is 80. What is its permittivity. *(H.S.S.C.E. 1997 S)*

Ans. Since dielectric constant and relative permittivity of a medium represent the same quantity, it implies that the relative permittivity (ε_r) of water is 80. The absolute permittivity (ε) of water will be $\varepsilon_0 \varepsilon_r$ *i.e.* $8 \cdot 854 \times 10^{-12} \times 80$ $C^2 N^{-1} m^{-2}$.

Q. 1.24. Force between two point electric charges kept at a distance d apart in air is F. If these charges are kept at the same distance in water, how does the force between them change ? *(C.B.S.E. 1997)*

Ans. It will become $\dfrac{F}{K}$, where K is dielectric constant of water.

Q. 1.25. Calculate the Coulomb's force between two α-particles separated by a distance of $3{\cdot}2 \times 10^{-15}$ m. *(C.B.S.E. 1992)*

Ans. Here, $r = 3 \cdot 2 \times 10^{-15}$ m ;

charge on α-particles, $q_1 = q_2 = 2 \times 1 \cdot 6 \times 10^{-19}$ C

$$\text{Now,} \quad F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}$$
$$= 9 \times 10^9 \times \frac{(2 \times 1{\cdot}6 \times 10^{-19})^2}{(3{\cdot}2 \times 10^{-15})^2} = \mathbf{90\ N}$$

Q. 1.26. Calculate the Coulomb's force between a proton and electron separated by $0 \cdot 8 \times 10^{-15}$ m. *(P.S.S.C.E. 1998 S ; C.B.S.E. 1992)*

Ans. Proceed as in VSQ 1.25.

Q. 1.27. If the distance between two equal point charges is doubled and their individual charges are also doubled, what would happen to the force between them ? *(I.S.C.E. 1995)*

Ans. Originally, force between the two charges,

$$F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{r^2}$$

When the individual charges and the distance between the charges are doubled, the force is given by

$$F' = \frac{1}{4\pi\varepsilon_0} \cdot \frac{2q \times 2q}{(2r)^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \cdot q}{r^2} = F$$

i.e. force will remain the same.

Q. 1.28. State the principle of superposition of forces in electrostatics. *(H.S.S.C.E. 2001)*

Ans. Refer to section 1.14.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 1.01. A comb run through one's dry hair attracts small bits of paper. Why ? What happens, if the hair is wet or if it is a rainy day ? *(Text Question)*

Ans. When a comb is run through dry hair, it gets charged. As such, it starts attracting small bits of paper. If the hair is wet or it is a rainy day, then in absence of friction, the comb will not get charged when run through hair. In absence of charge on the comb, the bits of paper will not be attracted.

Q. 1.02. Ordinary rubber is an insulator. But the special rubber tyres of aircrafts are made slightly conducting. Why is this necessary ? *(Text Question)*

Ans. During landing, the tyres of a space-craft get charged due to friction between tyres and ground. In case, the tyres are slightly conducting, the charge developed on the tyres will not stay on them and it will find its way (leak) to the earth.

Q. 1.03. Vehicles carrying inflammable materials usually have metallic ropes touching the ground during motion. Why ?

(P.S.S.C.E. 1999 ; H.P.S.S.C.E. 1998 ; Text Question)

Ans. Due to air friction, body of the vehicle also gets charged in addition to charge developed on tyres. In case, charge accumulation becomes large, it may prove hazardous to the vehicle carrying inflammable materials. So that it does not happen, metallic ropes from the vehicle are mde to touch the ground. Due to this, the charge on the vehicle leak to earth.

Q. 1.04. When you touch a metal object like a door handle on a dry winter day, you are likely to see a spark and feel a definite shock. We usually explain this by saying that we have built up a static charge. Why does this not happen on a humid day in the summer ?

Ans. When we build up a sizeable static charge and touch a metal object (door handle), the transfer of charge is in the form of a spark.

The static charge can build up on a substance, when it is well insulated from its surroundings. On a humid day in summer, the static charge can not build up. In fact, the charge leaks away as fast as it builds up. As on a humid day in the summer, we do not have static charge built on us ; no spark occurs, when we touch a metal object.

Q. 1.05. How many electrons are present in one coulomb of charge ? *(P.S.S.C.E. 1999 ; H.P.S.S.C.E. 1992)*

Ans. Let there be n electrons in one coulomb. From quantization of charge,

$$q = n\,e$$

$$\therefore \qquad n = \frac{q}{e} = \frac{1}{1 \cdot 6 \times 10^{-19}} = \mathbf{6 \cdot 25 \times 10^{18}}$$

Q. 1.06. Suppose we have a large number of identical particles, very small in size. Any of them at 10 cm separation repel with a force of 3×10^{-10} N.

(*a*) If one of them is at 10 cm from a group of *n* others, how strongly do you expect it to be repelled ?

(*b*) Suppose you measure the repulsion and find it 6×10^{-6} N ; how many particles were there in the group ?

Ans. **(*a*)** The group of n small charged particles must behave as a single point charge, so that it can have a separation of 10 cm from the one particle in question. Obviously, force on this particle due to the group of n particles is n times the force due to a single particle. Hence, force due to grou of n particles,

$$F = n \times 3 \times 10^{-10}\ \text{N}$$

(*b*) Here, $\quad F = 6 \times 10^{-6}$ N

$$\therefore \qquad n = \frac{F}{3 \times 10^{-10}} = \frac{6 \times 10^{-6}}{3 \times 10^{-10}} = \mathbf{2 \times 10^4}$$

Q. 1.07. Why can one ignore quantization of electri charge, when dealing with macroscopic *i.e.* large scal charges ? *(Text Question*

Ans. In practice, the charge on a charged body is ver large. On the other hand, the charge on an electron is ver small. When electrons are added to a body (negativel charged body) or removed from a body (positively charge body), the change taking place in the total charge on the bod is so small that the charge seems to be varying in a continuou manner. Therefore, quantization of electric charge can b ignored, when dealing with a large scale charged body.

Q. 1.08. Force of attraction between two point electri charges placed at a distance *d* in a medium is F. Wha distance apart should these be kept in the same mediun so that force between them becomes F / 3 ?

(C.B.S.E. 2001 S, 1998

Ans. Let q_1 and q_2 be the two point charges. Then, forc between the charges, when kept at a distance d apart,

$$F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{d^2}$$

Suppose that force between the two charges become F/3, when the charges are kept at a distance x apart. Then,

$$\frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{x^2} = \frac{F}{3} \quad \text{or} \quad \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{x^2} = \frac{1}{3}\left(\frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{d^2}\right.$$

$$\text{or} \qquad x = \sqrt{3}\, d$$

Q. 1.09. Bring out a comparison between the nature o electrostatic and gravitational forces.

Ans. The gravitational force between two bodies i because of their masses, while the electrostatic force is du to charge on them.

Points of similarities. 1. Both the forces are central i nature.

2. Both the forces obey inverse square law.

3. Both the forces are conservative in nature *i.e.* wor done in moving a body (mass in case of gravitational forc and charge in case of electrostatic force) between any tw points does not depend upon the path followed.

4. Both the forces are long range forces.

Points of dissimilarities. 1. Whereas the electrostati force may be attractive or repulsive, the gravitational forc is always attractive in nature.

2. The electrostatic force between two charged bodies i greatly affected by the medium, in which the two bodies ar located. There is no effect of medium on the gravitationa force.

3. Electrostatic force is very strong as compared t gravitational force. It can be easily shown that electrostati force between an electron and a proton is about 10^{38} times a large as the gravitational force between them.

Q. 1.10. What is the importance of Coulomb's law i vector form ? *(H.P.S.S.C.E. 1998 S*

Ans. From Coulomb's law in vector form, it directly follows that the forces exerted by two charges on each other are equal and opposite. Further, the force, which one charge exerts on the other, acts along the line joining the two charges *i.e.* electrostatic force is a central force.

Q. 1.11. Four point charges $q_A = 2\ \mu C$, $q_B = -5\ \mu C$, $q_C = 2\ \mu C$ and $q_D = -5\ \mu C$ are located at the corners of a square ABCD of side 10 cm. What is the force on charge of 1 μC placed at the centre of the square ? *(Text Question)*

Ans. Consider the square ABCD of each side 10 cm and centre O. The charge of 1 μC is placed at the point O. Obviously, OA = OB = OC = OD [Fig. 1.22].

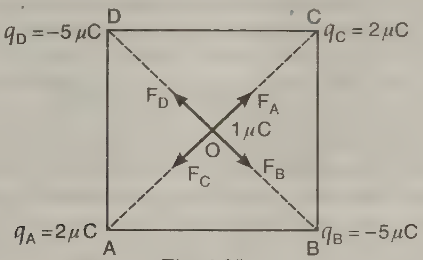

Fig. 1.22

Since $q_A = q_C$, the charge of 1 μC experiences equal and opposite forces due to charges q_A and q_C. Similarly, the charge of 1 μC experiences equal and opposite forces F_B and F_D due to charges q_B and q_D. Hence, the net force on charge of 1 μC due to the given arrangement of charges is zero.

Q. 1.12. State the principle of superposition. What is its use ?

Ans. The principle of superposition states that *when a number of charges are interacting, the total force on a given charge is vector sum of the forces exerted on it by all other charges.*

It is used to find force on a charge, when a group of charges are interacting.

Q. 1.13. Two identical point charges Q are kept at a distance *r* from each other. A third point charge *q* is placed on the line joining the above two charges, such that all the three charges are in equilibrium. What is the magnitude, sign and position of the third charge ? *(C.B.S.E. 1994)*

Ans. The charge q should be equal to $-\dfrac{Q}{4}$.

For detailed solution, refer to solved problem 1.14 or 1.15.

Q. 1.14. A charge *q* is placed at the centre of line joining two equal charges Q. Show that the system of three charges will be in equilibrium, if $q = -\dfrac{Q}{4}$. *(H.P.S.S.C.E. 2002)*

Ans. Refer to solved numerical problem 1.14 or 1.15.

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 1.01. Two identical metallic spheres of exactly equal masses are taken. One is given a positive charge Q coulomb and the other an equal negative charge by friction. Are their masses after charging equal ? *(I.I.T. 1983)*

Ans. When two bodies are rubbed together, electrons get removed from one body and these electrons so removed get transferred to the other body. The body from which electrons get removed becomes positively charged and the body to which electrons get transferred becomes negatively charged. Since an electron is a material particle, the mass of the positively charged body decreases and that of the negatively charged body increases.

Hence, when one of the two identical metallic spheres is charged positive and the other negative, their masses after charging will **not be equal.**

Q. 1.02. When a glass rod is rubbed with a silk cloth, charges appear on both. A similar phenomenon is observed with many other pairs of bodies. Explain, how this observation is consistent with the law of conservation of charge. *(Text Question)*

Ans. Before rubbing, both the glass rod and the silk cloth are electrically neutral. In other words, net charge on the glass rod and the silk cloth is zero. When the glass rod is rubbed with silk cloth, a few electrons from glass rod get transferred to the silk cloth. As a result, the glass rod becomes positively charged and the silk cloth negatively charged. Since the magnitude of the positive charge on the glass is same as that of negative charge on the silk cloth, the net charge on the system is still zero. Thus, the appearance of charges on glass rod and silk cloth is in accordance with the law of conservation of charge.

Q. 1.03. In filling the gasoline tank of an aeroplane, the metal nozzle of the hose from the gasoline truck is always carefully connected to the metal of the aeroplane by a wire, before the nozzle is inserted in the tank. Explain, why.

Ans. Since the aeroplane and the gasoline truck usually have wheels with rubber tyres, they are insulated from the ground. Further, the service ramps are usually made of concrete and are not necessarily good conductors to the earth. Therefore, inspite of grounding metallic ropes, the aeroplane and the truck could remain charged. A spark could jump and ignite the explosive gasoline, when the metal nozzle was brought near the aeroplane. The connection of metal of the aeroplane and the nozzle of the hose with a wire avoids any unbalance of charge and hence the risk of gasoline catching fire due to the spark.

Also, the stream of gasoline flowing out of the nozzle may become charged by friction. The charged gasoline would go into the aeroplane tank and charge it oppositely to the nozzle. Unless a good conducting path is provided so that the charges on the aeroplane and nozzle could recombine, a spark could result with disastrous consequences.

Q. 1.04. (*a*) If you accumulate a static charge and then touch a wooden frame of a door, you often find no spark or shock, although there would be, you touched the metal handle. Why ?

(*b*) Sometimes, if you touch the wooden frame and then touch the metal handle, there is no spark or shock in either case, although there would have been, if you had touched the handle first. Suggest an explanation.

Ans. (*a*) Metals are good conductors. When we are carrying a static charge and touch the metal handle of the door, the charge transfers to it immediately in the form of a spark and distributes itself quickly throughout the conductor.

When the wooden frame (insulator) of the door is touched, the charge is unable to flow through. As such, only a little charge may get transferred and there is no spark.

(*b*) When the wooden frame of the door is touched, it does not accept charge fast enough to cause a spark. However, if the contact lasts long, the charge may slowly flow away from us. When we subsequently touch the metal handle, there is no spark. It is because, there is no charge left on us, which may transfer to the handle and may cause a spark.

Q. 1.05. 'Automobile ignition failure occurs in damp weather.' Explain, why.

Ans. The insulating porcelain of the spark plugs accumulates a film of dirt. The surface dirt is hygroscopic and picks up moisture from air. Therefore, in humid weather, the insulating porcelain of the plugs becomes quasi-conductor. This allows an appreciable proportion of the spark to leak across the surface of the plug instead of discharging across the gap.

Q. 1.06. It is now believed that protons and neutrons are themselves built out of more elementary units called quarks. A proton and neutron consist of three quarks each. Two types of quarks, so called 'up quark' denoted by *u* of charge + 2 *e*/3 and the 'down quark' denoted by *d* of charge – *e*/3, together with electrons build up ordinary matter. Suggest a possible quark composition of a proton and neutron. *(Text Question)*

Ans. The charge on up quark (u) = $+2\,e/3$

and the charge on down quark (d) = $-e/3$

The charge on the proton is + *e* and it is made of three quarks. Therefore, the possible quark composition of proton is ***u u d***.

On the other hand, neutron is a neutral particle but it is also made of three quarks. For this, the possible composition of neutron is ***u d d***.

Q. 1.07. A glass rod rubbed with silk is brought close to two uncharged metallic spheres in contact with each other inducing charges on them as shown in Fig. 1.23. Describe what happens, when (*i*) the spheres are slightly separated, (*ii*) the glass rod is subsequently removed and finally (*iii*) the spheres are separated far apart. *(Text Question)*

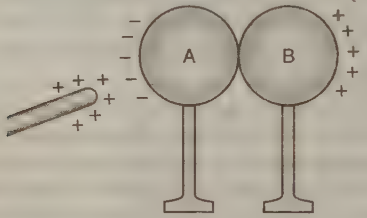

Fig. 1.23

Ans. (*i*) On separating the two spheres, the right face of sphere A will acquire positive induced charge and the left face of B will acquire negative induced charge.

(*ii*) If the glass rod is removed, the charges on the two spheres will disappear.

(*iii*) In this case also, charges on spheres will disappear.

Q. 1.08. Can a charged body attract another uncharged body ? Explain.

Or

Why does a charged glass rod attract a piece of paper ?

Ans. Yes, a charged body can attract another uncharged body. It is because, when the charged body is placed in front of the uncharged body, the induced charges of opposite kind are produced on the uncharged body. Due to this, the charged body attracts the uncharged body.

Q. 1.09. A positively charged glass rod attracts suspended pith-ball. Does it imply that the pith-b is negatively charged ?

Ans. The pith-ball can be uncharged also. The positive charged glass rod can attract the pith-ball due to induc charges of opposite kind produced on the pith-ball.

Q. 1.10. Can two balls having same kind of charge them attract each other ? Explain.

Ans. Yes, two balls having same kind of charge can attr each other, if one ball possesses charge quite large as compar to that on the other ball.

The reason is that when two charged balls are placed ne each other, they induce opposite kinds of charges on the fac of each other. Since on the ball having a small amount charge, quite a large amount of induced charge is produce two balls get attracted towards each other due to for between the large inducing charge of one ball and lar induced charge (opposite in nature) on the other ball.

Q. 1.11. The graph in Fig. 1.24 shows the electric for of repulsion on a tiny charged conducting sphere A a function of its separation from a large conducting sphe B. The sphere B has 10 times the charge on the sphere Explain the behaviour of the force between separations 2 and 1 cm.

Ans. When the spheres are at large separation, the for between the spheres varies as $\frac{1}{r^2}$ *i.e.* varies in the sar manner as between two point charges.

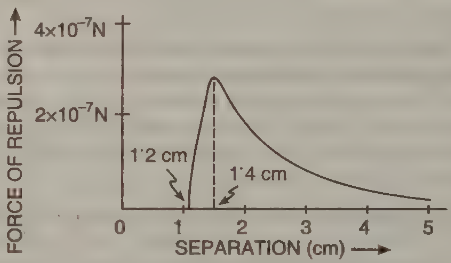

Fig. 1.24

As the spheres move closer, the charge on large sphe B is redistributed as shown in Fig. 1.25. As the spheres mo still more closely, the part of the large sphere B, which nearest to the small sphere A becomes negatively (opposite charged [Fig. 1.26] and it results in force of attraction betwe them.

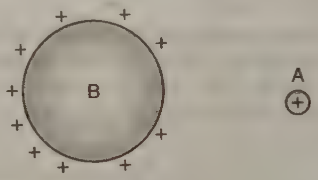

Fig. 1.25

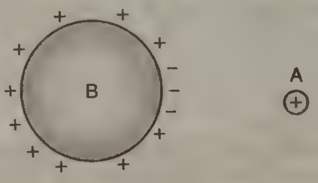

Fig. 1.26

Behaviour of the force between separations 2 cm and 1 cm : Refer to Fig. 1.24. At 2 cm, the force of repulsion between the spheres increases ; till at $1 \cdot 4$ cm, the force of repulsion becomes maximum. As the spheres move closer ($1 \cdot 2 \text{ cm} < r < 1 \cdot 4$ cm), the force of repulsion begins to fall due to the attractive force between the sphere A and the negative charge induced on sphere B. At $1 \cdot 2$ cm, the attractive force due to inductive effect equals the repulsion between the two positively charged spheres. As the spheres approach still more closely ($r < 1 \cdot 2$ cm), the net force between the spheres becomes strongly attractive.

Q. 1.12. Two large conducting spheres carrying charges q_1 and q_2 are brought close to each other. Is the magnitude of electrostatic force between them exactly given by $\frac{q_1 q_2}{4\pi\varepsilon_0 r^2}$, where r is the distance ?

Ans. The expression for electrostatic force between two charges q_1 and q_2 *i.e.*

$$F = \frac{q_1 q_2}{4\pi\varepsilon_0 r^2}$$

holds, when charges q_1 and q_2 are point charges only. The expression will not be true in case of large conducting spheres. It is because, when large conducting spheres are brought together, charge distribution will not remain uniform.

Q. 1.13. Check that the ratio $k\,e^2/G\,m_e\,m_p$ is dimensionless. Look up a table of physical constants and determine the value of this ratio. What does the ratio signify ?

Ans. $$\left[\frac{k\,e^2}{G m_e m_p}\right] = \frac{[\text{N m}^2\,\text{C}^{-2}]\times[\text{C}]^2}{[\text{N m}^2\,\text{kg}^{-2}]\times[\text{kg}]\times[\text{kg}]} = \text{no unit}$$

Since the ration $k\,e^2/G\,m_e\,m_p$ has no unit, it is **dimensionless.**

Now, $k = 9 \times 10^9\,\text{N m}^2\text{C}^{-2}$; $G = 6 \cdot 67 \times 10^{-11}\,\text{N m}^2\,\text{kg}^{-2}$;

$e = 1 \cdot 6 \times 10^{-19}$ C ; $m_e = 9 \cdot 1 \times 10^{-31}$ kg

and $m_p = 1 \cdot 66 \times 10^{-27}$ kg

$$\therefore \frac{k\,e^2}{G\,m_e\,m_p} = \frac{9\times10^9\times(1{\cdot}6\times10^{-19})^2}{6{\cdot}67\times10^{-11}\times9{\cdot}1\times10^{-31}\times1{\cdot}66\times10^{-27}}$$

$$= 2 \cdot 287 \times 10^{39}$$

The factor $\frac{k\,e^2}{G\,m_e\,m_p}$ represents the ratio of electrostatic force to the gravitational force between an electron and proton.

Q. 1.14. Is Coulomb's law in electrostatics applicable in all situations ?

Or

State the limitations of coulomb's law in electro-statics.

(P.S.S.C.E. 1999)

Ans. No, Coulomb's law in electrostatics does not hold in all the situations. It is applicable only in the following situations :

1. The electric charges must be ***stationary.***
2. The electric charges must be ***points in size.*** Coulomb's law does not apply to two charged bodies of finite sizes, say two charged spheres. It is because, the distribution of charge does not remain uniform, when the two bodies are brought together.

Q. 1.15. A bird perches on a bare high-power line and nothing happens to the bird. A man standing on the ground touches the same line and gets a fatal shock. Why ?

(Text Problem)

Ans. When a bird is perched on a bare high power line, the circuit does not get completed between the bird and the earth. Therefore, nothing happens to the bird.

When a man standing on ground touches the same line, the circuit between man and the earth gets completed. As a result, he gets a fatal shock.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. Explain, what is meant by quantization of charge. *(H.P.S.S.C.E. 1996 ; H.S.S.C.E. 1994 ; C.B.S.E. 1992 ; P.S.S.C.E. 1991)*
2. Explain conservation of charge giving two examples. *(H.S.S.C.E. 2000, 1998 ; P.S.S.C.E. 1994, 1991)*
3. Explain the following : (*i*) Conservation of electric charge (*ii*) Quantization of electric charge. *(P.S.S.C.E. 2001)*
4. Give six properties of electric charge. *(P.S.S.C.E. 1999 S)*
5. State Coulomb's law and derive definition of a unit charge (coulomb). *(P.S.S.C.E. 1999 ; H.S.S.C.E. 1996)*
6. State Coulomb's law of electrostatic force between two charges and state their limitations. Also deduce unit charge from these laws. *(P.S.S.C.E. 2000)*
7. Write Coulomb's law in vector form. Derive the definition of one coulomb. *(H.S.S.C.E. 1992)*
8. Write the vector form of force acting between two charges q_1 and q_2 having $\vec{r}_1$ and $\vec{r}_2$ as their position vectors respectively. *(H.P.S.S.C.E. 2000)*
9. State Coulomb's law of electrostatic force and express this law in vector form. *(P.S.S.C.E. 2000)*
10. State Coulomb's law in vector form and prove that $\vec{F}_{21} = -\vec{F}_{12}$, where letters have their usual meanings. *(H.S.S.C.E. 1997)*
11. What is meant by continuous charge distribution ? Define linear charge density. Obtain expression for force on a charge q due to a continuous distribution of charges along a line.
12. Define surface charge density. Obtain expression for force on a charge q due to a continuous distribution of charges over a surface.

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. Explain the terms : (*i*) quantization of charge (*ii*) conservation of charge (*iii*) additive nature of charge.
2. (*a*) Define dielectric constant of a medium in terms of force between two electric charges. *(P.S.S.C.E. 1997 S ; C.B.S.E. 1997)*
   (*b*) Explain, what is meant by dielectric constant. Give some example. *(P.S.S.C.E. 1994)*
3. State Coulomb's law in electrostatics. Express the same in SI units. Mention two similarities and two dissimilarities between electrostatic and gravitational interactions. *(C.B.S.E. Sample Q. Paper)*

4. State Coulomb's law in electrostatics. Express it in vector form. What is importance of expressing it in vector form ?
5. State the principle of superposition and use it to obtain the expression for the total electric force exerted at a point charge due to an assembly of n discrete point charges. *(H.S.S.C.E. 2002)*
6. State principle of superposition of charges. Hence, expres the force on a charge q due to a discrete distribution of charges in terms of their position vectors.
7. Distinguish between linear, surface and volume charg density. Obtain expression for force on a charge q due t continuous distribution of charge over a volume.

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Quantization of charge

1. Which is bigger, a coulomb or charge on an electron ? How many electronic charges form one coulomb of charge ? [**Ans.** One coulomb, $6{\cdot}25 \times 10^{18}$]
2. How many electrons must be removed from a conductor, so that it acquires a charge of 3·5 nC ?[**Ans.** $2{\cdot}1875 \times 10^{10}$]
3. What is the amount of charge possessed by 1 kg of electrons ? Given that mass of an electron is $9{\cdot}1 \times 10^{-31}$ kg. [**Ans.** $1{\cdot}76 \times 10^{11}$ C]
4. A polythene piece rubbed with wool is found to have a negative charge of $3{\cdot}6 \times 10^{-7}$ C. Calculate the number of electrons transferred from wool to polythene. If an electron has a mass $9{\cdot}1 \times 10^{-31}$ kg, find the mass transferred to polythene. [**Ans.** $2{\cdot}25 \times 10^{12}$; $2{\cdot}05 \times 10^{-18}$ kg]
5. Assume that each of copper has one free electron. Estimate the number of free electrons in 1 mg of copper. Given that atomic weight of copper = 63·5 and Avogadro number = $6{\cdot}02 \times 10^{23}$. What is the charge possessed by these free electrons ? [**Ans.** $9{\cdot}48 \times 10^{18}$; 1·517 C]
6. Estimate the number of free electrons in 1 g of water and the negative charge possessed by them. Given that Avogadro number = $6{\cdot}02 \times 10^{23}$ and molecular weight of water = 18. [**Ans.** $3{\cdot}344 \times 10^{23}$; $5{\cdot}35 \times 10^{4}$ C]

Type B. On Coulomb's law in electrostatics

7. Two equal charges placed in air separated by a distance 3 m repel each other with force 0· 1gf. Calculate the magnitude of either of the charges. *(P.S.S.C.E. 1999)* [**Ans.** $9{\cdot}9 \times 10^{-7}$ C]
8. Two electrons have been removed from each atom. Find the distance between two such atoms, if they repel each other with a force of $8{\cdot}8 \times 10^{-9}$ N, when placed in free space. *(P.S.S.C.E. 2002)* [**Ans.** $3{\cdot}24 \times 10^{-10}$ m]
9. How far apart should the two electrons be, if the force each exerts on the other is equal to the weight of the electron ? Given that $\varepsilon_0 = 8{\cdot}854 \times 10^{-12}$ SI unit, $e = 1{\cdot}6 \times 10^{-19}$ C and $m_e = 9{\cdot}1 \times 10^{-31}$ kg. *(H.S.S.C.E. 2002)* [**Ans.** 5·08 m]
10. Calculate the magnitude of the electrostatic force exerted by the proton on the electron in the hydrogen atom and compare it with the weight of the electron. Given that mass of electron is $9{\cdot}1 \times 10^{-31}$ kg, charge on electron is $1{\cdot}6 \times 10^{-19}$ C and radius of hydrogen atom is 0·53 Å. [**Ans.** $8{\cdot}2 \times 10^{-8}$ N ; $9{\cdot}2 \times 10^{21}$]
11. Two identical balls each have a mass of 10 g. What charges should these balls be given so that their interaction equalizes the force of universal gravitation acting between them ? The radii of the balls may be ignored in comparison to distance between them. [**Ans.** $8{\cdot}56 \times 10^{-13}$ C]
12. What equal charges would have to be placed on earth and moon to neutralize their gravitational force of attraction ? Given that mass of earth $=10^{25}$ kg and mass of moon $= 10^{23}$ kg. [**Ans.** $8{\cdot}56 \times 10^{13}$ C]
13. Calculate the ratio of electrostatic to gravitational force between two electrons placed at certain distance in air. Given that $m_e = 9{\cdot}1 \times 10^{-31}$ kg, $e = 1{\cdot}6 \times 10^{-19}$ C and $G = 6{\cdot}6 \times 10^{-11}$ N m² kg⁻². [**Ans.** $4{\cdot}2 \times 10^{42}$]
14. A pith-ball A of mass 9×10^{-5} kg carries a charge of + 5 μ What must be the magnitude and sign of the charge on pith-ball B held 2 cm directly above the pith-ball A suc that the pith-ball A remains stationary ? [**Ans.** $7{\cdot}84 \times 10^{-12}$ C (negative
15. Two point charges q_1 and q_2 are 3 m apart and the combined charge is 20 μC. If one repels the other with force of 0·075 N, what are the two charges ? *(H.S.S.C.E. 2001 ; P.S.S.C.E. 1991)* [**Ans.** 15 μC, 5 μ
16. The force between two equal charges placed in a mediu at a distance of 9 cm from each other is 16 dyne. O increasing one of the charges by 56 statC, it is found th the distance between the charges must be changed by 3 c in order to keep the force between them the sam Calculate the magnitude of the charges and the dielectr constant of the medium. Given, 1 C = 3×10^{9} statC. [**Ans.** 72 statC ;
17. The distance between two equal balls having unlik charges is 2 cm. The radii of the balls are much less tha the distance between them. The balls attract each oth with a force of 36×10^{-5} N. After, the balls have bee connected by a wire and the latter has been removed, th balls repel each other with a force of $20{\cdot}25 \times 10^{-5}$ Determine the original charges on the balls. [**Ans.** 8×10^{-9} C, -2×10^{-9}
18. Two charged particles having charge 5 μC each are joine by an insulating string of length 1 m and the system placed on a smooth horizontal table. Find the tension i the string. [**Ans.** 0·225 N
19. Two small spheres each of mass 10 mg are suspended fro a point by threads 0·5 m long. They are equally charge and repel each other to a distance of 0·28 m. If $g = 10$ m s what is the charge on each ? *(Karnataka, 199* [Ans. $1{\cdot}594 \times 10^{-8}$
20. Two small spheres each of mass 10^{-6} kg are suspende from a point by silk threads 50 cm long. These are equall charged and repel each other to a distance of 20 cm apa Calculate the charge on each sphere. Take $g = 10$ m s^{-2} *(P.S.S.C.E. 1998 S)* [**Ans.** $3{\cdot}01 \times 10^{-9}$
21. Two pith-balls each of mass 5×10^{-4} kg are suspended fro the same point by silk threads 0·2 m long. Equal charg are given to the balls, which separate, until the threa enclose an angle of 30°. Calculate the charge on each pit ball. [**Ans.** $3{\cdot}954 \times 10^{-8}$
22. Two similar small metallic spheres are suspended by equ threads from the same point. When either sphere is give a similar charge of 36 stat C, the distance between them 6 cm. If the length of each thread is 5 cm, find the mass each sphere and the tension in each thread. [**Ans.** 0·049 g ; 60 dyn
23. Two equal small spheres each weighing 1 g are hung b equal silk threads attached to the same point. The spher are charged when in contact and come to rest with the centres 2 cm apart and 20 cm vertically below the point support. Find the charge on each sphere, if $g = 980$ cm s How will the force of repulsion be affected, if the plate glass of K = 8 is placed between the spheres ? [Ans. 14 statC ; 6·125 dyn

24. Three equally charged objects are located as shown in Fig. 1.27. The electric force exerted by A and B is $3{\cdot}0 \times 10^{-6}$ N.

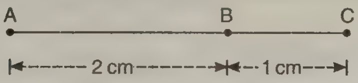

Fig. 1.27

(*a*) What electric force C exert upon B ?
(*b*) What is the net electric force on B ?

[**Ans.** (*a*)$12{\cdot}0 \times 10^{-6}$ N (along BA) ; (*b*) $9{\cdot}0 \times 10^{-6}$ N (along BA)]

25. Three small charged spheres, with equal charges on them are placed as shown in Fig. 1.28. A and C are fixed in position and B can move. C exerts a force of 4×10^{-6} N on B.

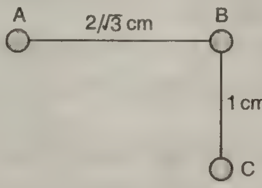

Fig. 1.28

(*a*) What force A exerts on B ?
(*b*) What is the net force on B ?

[**Ans.** (*a*) 3×10^{-6} N ; (*b*) 5×10^{-6} N in a direction 36·9° east of north]

26. Two equal positive charges, each of 5 μC interact with a third positive charge of 10 μC situated as shown in Fig. 1.29. Find the magnitude and direction of the force experienced by the charge of 10 μC.

[**Ans.** 0·161 N (along CO)]

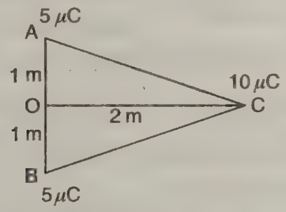

Fig. 1.29

27. Three equal charges, each having a charge of $+2 \times 10^{-6}$ C are placed at the three corners of a right angled triangle of sides 3 cm, 4 cm and 5 cm. Find the force on the charge at the right-angled corner.

[**Ans.** 45·9 N at an angle of 60·64° with the side of length 4 cm]

28. Two charges of $+2\times 10^{-8}$ C and -10^{-8} C are placed at points A and B respectively. Find the resultant force on a charge of 1 μC held at point P, such that AP = 10 cm, BP = 5 cm and $\angle$APB = 90°.

[**Ans.** $4{\cdot}0 \times 10^{-2}$ N making an angle of 63·4° with AP]

Type C. On Superposition principle

29. Charges of $+5\,\mu$C, $+10\,\mu$C and $-10\,\mu$C are placed in air at the corners A, B and C of an equilateral triangle ABC, having each side equal to 5 cm . Determine the resultant force on the charge at A. [**Ans.** 180 N (parallel to BC)]

30. Four charges $+q, +q, -q$ and $-q$ are placed respectively at the four corners A, B, C and D respectively of a square of side a. Calculate the force on a charge Q placed at the centre of the square.

$$\left[\textbf{Ans.}\ \frac{1}{4\pi\varepsilon_0}\cdot\frac{4\sqrt{2}\,Qq}{a^2},\ \text{(parallel to AD or BC)}\right]$$

31. Two opposite corners of a square carry Q charge each and the other two opposite corners of the square carry q charge each. If the resultant force on Q is zero, how are Q and q related ? [**Ans.** $Q = -2\sqrt{2}\,q$]

MISCELLANEOUS PROBLEMS

32. A copper atom consists of copper nucleus surrounded by 29 electrons. The atomic weight of copper is 63·5 g mole^{-1}. Let us now take two pieces of copper each weighing 10 g. Let us transfer one electron from one piece to another for every 100 atoms in that piece. What will be the coulomb force between the two pieces after the transfer of electrons, if they are 1 cm apart ? Avogadro number $= 6 \times 10^{23}$ mole^{-1}, charge on an electron $= -1{\cdot}6 \times 10^{-19}$ C. (*Roorkee, 1980*)

[**Ans.** $2{\cdot}06 \times 10^{18}$ N (attractive)]

33. A small cork ball with a mass 0·58 g is suspended from a thread 10 cm long. Another ball is fixed at a distance 10 cm from the point of suspension and at a distance of 5 cm from the thread as shown in Fig. 1.30. What should the magnitude of the like and equal charges on the balls be to deflect the thread through 30° ? [**Ans.** 181·16 statC]

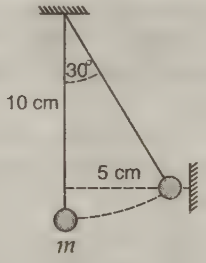

Fig. 1.30

34. A particle of mass m and carrying charge $-q_1$ is moving around a charge $+q_2$ along a circular path of radius r. Prove that period of revolution of the charge $-q_1$ about $+q_2$ is given by

$$T = \sqrt{\frac{16\pi^3\varepsilon_0 m r^3}{q_1 q_2}}$$

35. Two point electric charges of values q and $2q$ are kept at a distance d apart from each other in air. A third charge Q is to be kept along the same line in such a way that the net force acting on q and $2q$ is zero. Calculate the position of charge Q in terms of q and d. (*C.B.S.E. 1998*)

[**Ans.** $x = d/(\sqrt{2}+1)$ or $-d/(\sqrt{2}-1)$, where x is distance of charge Q from q]

36. Two fixed point charges 4 Q and 2 Q are separated by a distance x. Where should a third point charge q be placed for it to be in equilibrium ? (*P.S.S.C.E. 1999*)

[**Ans.** At a distance 0·586 x or 3·414 x from charge 4 Q]

37. Two free point charges $+4\,q$ and $+q$ are at a distance a apart. Where should a third point charge Q be placed between them so that the entire system is in equilibrium ? What will be the magnitude and sign of the charge Q ?

[**Ans.** At a distance $2\,a/3$ from the charge $+4\,q$; $Q = 4\,q/9$ (negative)]

38. It is required to hold four equal point charges $+q$ in equilibrium at the corners of a square. Find the point charge that will do this, if placed at the centre of the square.

$$\left[\textbf{Ans.}\ \frac{1+2\sqrt{2}}{4}\,q\ \text{(negative)}\right]$$

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. $n = \frac{q}{e} = \frac{1\,\text{C}}{1\cdot 6 \times 10^{-19}\,\text{C}} = \mathbf{6{\cdot}25 \times 10^{18}}$

2. $n = \frac{q}{e} = \frac{3\cdot 5 \times 10^{-9}\,\text{C}}{1\cdot 6 \times 10^{-19}\,\text{C}} = \mathbf{2{\cdot}1875 \times 10^{10}}$

3. $n = \frac{\text{M}}{m_e} = \frac{1\,\text{kg}}{9\cdot 1 \times 10^{-31}\,\text{kg}} = 1{\cdot}1 \times 10^{30}$

   Therefore, charge on 1 kg of electrons,

   $q = n\,e = 1{\cdot}1 \times 10^{30} \times 1{\cdot}6 \times 10^{-19} = \mathbf{1{\cdot}76 \times 10^{11}\ C}$

4. $n = \frac{q}{e} = \frac{-3\cdot 6 \times 10^{-7}\,\text{C}}{-1\cdot 6 \times 10^{-19}\,\text{C}} = \mathbf{2{\cdot}25 \times 10^{12}}$

   Therefore, mass transferred from wool to polythene,

   $\text{M} = n \times m_e = 2{\cdot}25 \times 10^{12} \times 9{\cdot}1 \times 10^{-31}$

   $= \mathbf{2{\cdot}05 \times 10^{-18}\ kg}$

5. Number of atoms in 1 g of copper,

   $n = \frac{\text{Avogadro number}}{\text{atomic weight}} = \frac{6\cdot 02 \times 10^{23}}{63\cdot 5} = 9{\cdot}48 \times 10^{21}$

   Therefore, number of atoms *i.e.* number of free electrons in 1 mg of copper,

   $n' = 9{\cdot}48 \times 10^{21} \times 10^{-3} = \mathbf{9{\cdot}48 \times 10^{18}}$

   Charge possessed by these free electrons,

   $q = n'\,e = 9{\cdot}48 \times 10^{18} \times 1{\cdot}6 \times 10^{-19} = \mathbf{1{\cdot}517\ C}$

6. One molecule of water (H_2O) contains 2 + 8 *i.e.* 10 electrons.

   Number of molecules in 1 g of water,

   $n = \frac{\text{Avogadro number}}{\text{atomic weight}} = \frac{6\cdot 02 \times 10^{23}}{18} = 3{\cdot}344 \times 10^{22}$

   Therefore, number of electrons in 1 g of water,

   $n' = n \times 10 = 3{\cdot}344 \times 10^{22} \times 10 = \mathbf{3{\cdot}344 \times 10^{23}}$

   The negative charge possessed by 1 g of water,

   $q = n'\,e = 3{\cdot}344 \times 10^{23} \times 1{\cdot}6 \times 10^{-19} = \mathbf{5{\cdot}35 \times 10^{4}\ C}$

7. For $q_1 = q_2 = q$ (say),

   $\text{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{r^2}$ or $q = \sqrt{4\pi\varepsilon_0\,\text{F}} \times r$

   Setting $\text{F} = 0{\cdot}1\ \text{gf} = 0{\cdot}1 \times 10^{-3}\ \text{kg f} = 0{\cdot}1 \times 10^{-3} \times 9{\cdot}8\ \text{N}$

   and $r = 3$ m, we get

   $q = \mathbf{9{\cdot}9 \times 10^{-7}\ C}$

8. When two electrons are removed from an atom, charge on atom

   $q = +2 \times 1{\cdot}6 \times 10^{-19} = +3{\cdot}2 \times 10^{-19}\ \text{C}$

   For $q_1 = q_2 = q$, we have

   $\text{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{r^2}$ or $r = \left(\frac{1}{4\pi\varepsilon_0 \text{F}}\right)^{1/2} \times q$

   Setting $\text{F} = 8{\cdot}8 \times 10^{-9}$ N, we get

   $r = \mathbf{3{\cdot}24 \times 10^{-10}\ m}$

9. $\frac{1}{4\pi\varepsilon_0} \cdot \frac{e \times e}{r^2} = m_e\,g$ or $r = \left(\frac{1}{4\pi\varepsilon_0\,m_e\,g}\right)^{1/2} \times e$

   Setting $m_e = 9{\cdot}1 \times 10^{-31}$ kg ; $e = 1{\cdot}6 \times 10^{-19}$ C ;

   $\varepsilon_0 = 8{\cdot}854 \times 10^{-12}$ SI units, we get

   $r = \mathbf{5{\cdot}08\ m}$

10. If e is magnitude of charge on an electron or a proton, then

    $\text{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{e \times e}{r^2}$

    Setting $e = 1{\cdot}6 \times 10^{-19}$ C and $r = 0{\cdot}53$ Å $= 0{\cdot}53 \times 10^{-10}$ m, w get

    $\text{F} = \mathbf{8{\cdot}2 \times 10^{-8}\ N}$

    Also, $\frac{\text{F}}{m_e g} = \frac{8\cdot 2 \times 10^{-8}}{9\cdot 1 \times 10^{-31} \times 9\cdot 8} = \mathbf{9 \cdot 2 \times 10^{21}}$

11. If q is charge given to each ball, then

    $\frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{r^2} = \text{G}\frac{m \times m}{r^2}$ or $q = \sqrt{4\pi\varepsilon_0\,\text{G}} \times m$

    Setting $\text{G} = 6{\cdot}6 \times 10^{-11}\ \text{N m}^2\ \text{kg}^{-2}$ and

    $m = 10\ \text{g} = 10 \times 10^{-3}$ kg, we get

    $q = \mathbf{8{\cdot}56 \times 10^{-13}\ C}$

12. If q is charge placed on earth and moon, then

    $\frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{r^2} = \text{G}\frac{\text{M}_{earth} \times \text{M}_{moon}}{r^2}$

    or $q = \sqrt{4\pi\varepsilon_0\,\text{G}\,\text{M}_{earth} \times \text{M}_{moon}}$

    Setting $\text{G} = 6{\cdot}6 \times 10^{-11}\ \text{N m}^2\ \text{kg}^{-2}$; $\text{M}_{earth} = 10^{25}$ kg an $\text{M}_{moon} = 10^{23}$ kg, we get

    $q = \mathbf{8{\cdot}56 \times 10^{13}\ C}$

13. $\frac{\text{F}_{elec}}{\text{F}_{grav}} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{e \times e}{r^2} \Big/ \text{G}\frac{m_e \times m_e}{r^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{e^2}{\text{G}m_e^{\,2}}$

    Setting $\text{G} = 6{\cdot}6 \times 10^{-11}\ \text{N m}^2\ \text{kg}^{-2}$; $m_e = 9{\cdot}1 \times 10^{-31}$ kg an $e = 1{\cdot}6 \times 10^{-19}$ C, we get

    $\frac{\text{F}_{elec}}{\text{F}_{grav}} = \mathbf{4{\cdot}2 \times 10^{42}}$

14. Proceed as in solved problem no. 1.06.

15. $\text{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}$ or $q_1 q_2 = 4\pi\varepsilon_0 \text{F} r^2$

    Setting F = 0·075 N and $r = 3$ m, we get

    $q_1 q_2 = 7{\cdot}5 \times 10^{-11}$ ...(i

    Also, $q_1 + q_2 = 20\ \mu\text{C} = 20 \times 10^{-6}\ \text{C}$ ...(

    From equation (*i*) and (*ii*), it can be obtained that

    $q_1 = \mathbf{15 \times 10^{-6}\ C}$ and $q_2 = \mathbf{5 \times 10^{-6}\ C}$

16. $\text{F} = \frac{1}{\text{K}} \cdot \frac{q_1 q_2}{r^2}$ (in cgs system)

    In first case **:** Setting $q_1 = q_2 = q$; F = 16 dyne and $r = 9$ cn we have

    $16 = \frac{1}{\text{K}}\frac{q^2}{81}$ ...(

    In second case **:** Setting $q_1 = q$, $q_2 = q + 56$; F = 16 dyne an $r = 9 + 3 = 12$ cm, we have

    $16 = \frac{1}{\text{K}}\frac{q \times (q + 56)}{144}$ ...(i

    From equations (*i*) and (*ii*), we get

    $q = \mathbf{72\ statC}$

    Using equation (*i*), we get

    $\text{K} = \mathbf{4}$

17. Let q_1 and $-q_2$ be the charges on two balls.

    Before connecting with a wire :

    $\text{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}$ or $q_1 q_2 = 4\pi\varepsilon_0 \text{F} r^2$

    Setting $\text{F} = 36 \times 10^{-5}$ N and $r = 2\ \text{cm} = 0 \cdot 02$ m, we get

    $q_1 q_2 = 16 \times 10^{-18}$ ...(

After connecting with a wire : Let q' be charge on each ball. Then,

$$q' = \frac{q_1 + (-q_2)}{2} = \frac{q_1 - q_2}{2}$$

$$\therefore \quad F' = \frac{1}{4\pi\varepsilon_0} \cdot \frac{(q_1 - q_2)/2 \times (q_1 - q_2)/2}{r^2}$$

or $\quad q_1 - q_2 = 4 \times 4\pi\varepsilon_0 F' r^2$

Setting $F' = 20·25 \times 10^{-5}$ N and $r = 0·02$ m, we get

$q_1 - q_2 = 6 \times 10^{-9}$ ...(*ii*)

Solving equations (*i*) and (*ii*), we obtain

$q_1 = \mathbf{8 \times 10^{-9}}$ **C** and $q_2 = \mathbf{2 \times 10^{-9}}$ **C (negative)**

18. Tension in the string,

T = force of repulsion between the charges

or $\quad T = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{r^2}$

Setting $q = 5\ \mu C = 5 \times 10^{-6}$ C and $r = 1$ m, we get

T = 0·225 N

19. Proceed as in solved problem no. 1.10.

20. Proceed as in solved problem no. 10.

21. Refer to Fig. 1.16 :

Here, AS = 0 · 2 m and $\theta = 30°/2 = 15°$

According to triangle law of forces,

$$\frac{F}{OA} = \frac{mg}{SO} = \frac{T}{AS} \quad \text{or} \quad F = mg \times \frac{OA}{SO}$$

or $\quad \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{(AB)^2} = mg \times \frac{OA}{SO} = mg \tan\theta$

Setting $m = 5 \times 10^{-4}$ kg, $g = 9·8$ m s^{-2} and

AB = 2 × OA = 2 × AS sin 15°, we get

$q = \mathbf{3·954 \times 10^{-8}}$ **C**

22. Refer to Fig. 1.15. Here, AB = 6 cm and AS = 5 cm

Now, $\quad F = \frac{q \times q}{(AB)^2}$ (in cgs system)

Setting $q = 36$ stat C, we get

F = 36 dyne

As obtained in problem no. 21,

$$\frac{F}{OA} = \frac{mg}{SO} = \frac{T}{AS}$$

$$\therefore \quad mg = F \times \frac{SO}{OA} \quad \text{and} \quad T = F \times \frac{AS}{OA}$$

Now, OA = AB/2 = 3 cm and SO = $\sqrt{AS^2 - OA^2}$ = 4 cm

Taking $g = 980$ cm s^{-2}, we get

$m = \mathbf{0·049}$ **g** and **T = 60 dyne**

23. Refer to Fig 1.15. Here, AB = 2 cm and SO = 20 cm

Proceeding as in problem no. 21, it can be obtained that

$$\frac{q \times q}{(AB)^2} = mg \times \frac{OA}{SO} \quad \text{(in cgs system)}$$

Setting $m = 1$ g, $g = 980$ cm s^{-2} and OA = AB/2 = 1 m, we get

$q = \mathbf{14}$ **statC**

On introducing dielectric : $F = \frac{1}{K} \cdot \frac{q \times q}{(AB)^2}$

Setting K = 8, we get

F = 6·125 dyne

24. Here, AB = 2 cm = 0·02 m and BC = 1 cm = 0·01 m

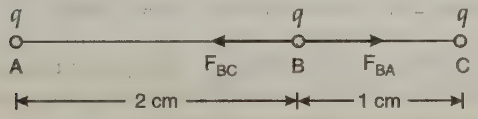

Fig. 1.31

Let charge on each object be q.

Now, $\quad F_{BA} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{(AB)^2}$

Setting $F_{BA} = 3·0 \times 10^{-6}$ N, we get

$q = 3·65 \times 10^{-8}$ N

(*a*) $F_{BC} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{(BC)^2}$ **= 12·0 × 10⁻⁶ N (along BA)**

(*b*) Net force on charge at B,

$F = F_{BC} - F_{BA} = 12·0 \times 10^{-6} - 3·0 \times 10^{-6}$

$= \mathbf{9·0 \times 10^{-6}}$ **N (along BA)**

25. Here, AB = $\frac{2}{\sqrt{3}}$ cm = $\frac{0 · 02}{\sqrt{3}}$ m ; BC = 1 cm = 0·01 m

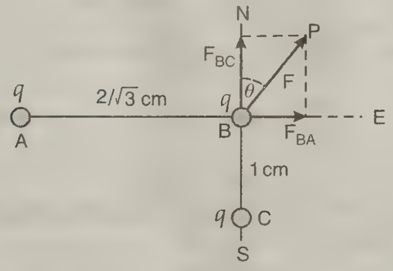

Fig. 1.32

Let q be charge on each object.

Now, $\quad F_{BC} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{(BC)^2}$

Setting $F_{BC} = 4 \times 10^{-6}$ N, we get

$q = 2·1 \times 10^{-10}$ C

(*a*) $F_{BA} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q \times q}{(AB)^2}$ **= 3 × 10⁻⁶ N (along BE)**

(*b*) Net force on charge at B,

$F = \sqrt{(F_{BA})^2 + (F_{BC})^2}$ **= 5 × 10⁻⁶ N (along BP)**

If the direction of F makes an angle θ with NS-line, then

$\tan\theta = \frac{F_{BA}}{F_{BC}} = 0·7500$ or $\theta = \mathbf{36·9°}$ **(east of north)**

26. Here, $q_A = q_B = 5\ \mu C = 5 \times 10^{-6}$ C ; $q_C = 10\ \mu C = 10 \times 10^{-6}$ C

AC = OC = $\sqrt{1^2 + 2^2} = \sqrt{5}$ m

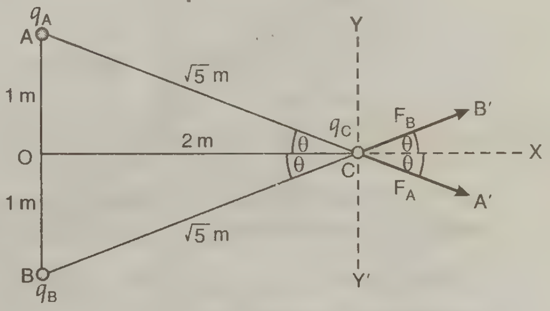

Fig. 1.33

Let F_A and F_B be the forces exerted by charges q_A and q_B on q_C. Then,

$F_A = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A \times q_B}{(AC)^2}$ m = 0·09 N (along CA')

Similarly, $F_B = 0·09$ N (along CB')

Resolve the forces F_A and F_B into rectangular components along X-axis and Y-axis. The components along Y-axis are equal and opposite and hence cancel each other, while the components along X-axis are equal and in the same direction. Therefore, net force on charge at C,

$$F = 2\,F_A \cos\theta = 2 \times 0{\cdot}09 \times \frac{2}{\sqrt{5}} = \mathbf{0{\cdot}161\ N\ (along\ CX)}$$

27. Here, $q_A = q_B = q_C = +2 \times 10^{-6}$ C ;
AB = 3 cm = 0·03 m, BC = 4 cm = 0·04 m and
AC = 5 cm = 0·05 m

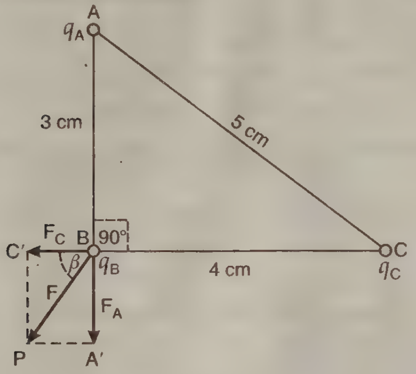

Fig. 1.34

Let F_A and F_B be the forces exerted by charges q_A and q_C on charge q_B at point B. Then,

$$F_A = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A \times q_B}{(AB)^2} = 40\ \text{N (along BA')}$$

and $$F_C = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_C \times q_B}{(BC)^2} = 22{\cdot}5\ \text{N (along BC')}$$

The resultant force on charge at B,

$$F = \sqrt{F_A^{\,2} + F_C^{\,2}} = \mathbf{45{\cdot}9\ N\ (along\ BP)}$$

If the direction of F makes an angle β with side BC, then

$$\tan\beta = \frac{F_A}{F_C} = 1{\cdot}7778 \quad \text{or} \quad \boldsymbol{\beta = 60{\cdot}64°}\ \textbf{(with side BC)}$$

28. Proceed as in problem no. 27.

29. Proceed as in solved problem no. 1.12.

30. Here, AB = BC = CD = DA = a

Obviously, AO = BO = CO = DO = $a \cos 45° = a/\sqrt{2}$

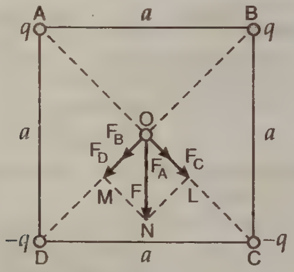

Fig. 1.35

Let F_A, F_B, F_C and F_D be the forces exerted by charges at points A, B, C and D on charge Q at point O. It follows that

$$F_A = F_B = F_C = F_D = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q \times Q}{(a/\sqrt{2})^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2qQ}{a^2}$$

The resultant of the forces F_A and F_C,

$$F_1 = F_A + F_C = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2qQ}{a^2} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{2qQ}{a^2}$$

or $$F_1 = \frac{1}{4\pi\varepsilon_0}\cdot\frac{4qQ}{a^2}\ \text{(along OL)}$$

Similarly, resultant of the forces F_B and F_D,

$$F_2 = F_B + F_D = \frac{1}{4\pi\varepsilon_0}\cdot\frac{4qQ}{a^2}\ \text{(along OM)}$$

Therefore, resultant force on charge Q,

$$F = \sqrt{F_1^{\,2} + F_2^{\,2}} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{4\sqrt{2}\,q\,Q}{a^2}\ \textbf{(along ON)}$$

Since forces F_1 and F_2 are equal in magnitude, the resultan force F will act along the bisector of ∠COD *i.e.* **parallel t side AD or BC.**

31. Let each side of the square be of length a.

Then, $AC = \sqrt{a^2 + a^2} = \sqrt{2}\,a$

It follows that resultant force on charge at point C can b zero, if charges at points B and D are negative in natur Then, the forces F_A, F_B and F_D will act on charge at poin C as shown in the Fig. 1.36.

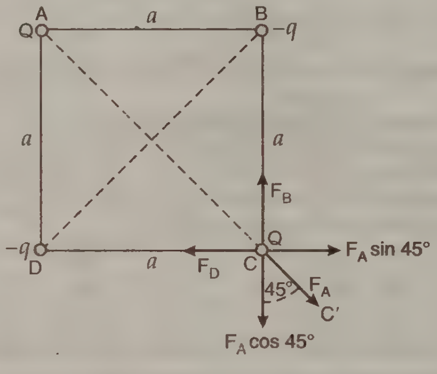

Fig. 1.36

So that resultant force on charge at point C is zero,

$F_B = F_A \cos 45°$ ...(i

and $F_D = F_A \sin 45°$ ...(i

From equation (*i*), we have

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{(-q)\times Q}{BC^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Q \times Q}{AC^2} = \cos 45°$$

or $$= -\frac{q}{a^2} = \frac{Q}{(\sqrt{2}\,a)^2} \times \frac{1}{\sqrt{2}} \quad \text{or} \quad \mathbf{Q = -2\sqrt{2}\,q}$$

32. Here, Avogadro number, N = 6×10^{23} mole^{-1} and atomic weight of copper, A = 63·5 g mole^{-1}.

Therefore, number of atoms in 10 g of copper,

$$n = \frac{N}{A} \times 10 = \frac{6 \times 10^{23} \times 10}{63{\cdot}5} = 9{\cdot}45 \times 10^{22}$$

Since one electron per 100 atoms is transferred from coppe piece A to B, the charge on copper piece A,

$$q_A = +\frac{n}{100} \times e = +151{\cdot}2\ \text{C}$$

Obviously, charge on copper piece B,

$$q_B = -151{\cdot}2\ \text{C}$$

Force between two copper pieces,

$$F = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A \times q_B}{r^2}$$

Setting r = 1 cm = 0·01 m, we get

$$\mathbf{F = 2{\cdot}06 \times 10^{18}\ N\ (attractive)}$$

33. Let q be charge on each ball. Suppose that cork ball A i deflected to position A′, so that ∠A′SO = 30°.

Then, OA′ = A′S sin 30° = 10 × 0·5 = 5 cm

∴ A′B = 10 cm = 0·1 m

It follows that SA′B is an equilateral triangle. Th electrostatic force of repulsion F and weight $m\,g$ of the cor ball will act as shown in Fig. 1.37.

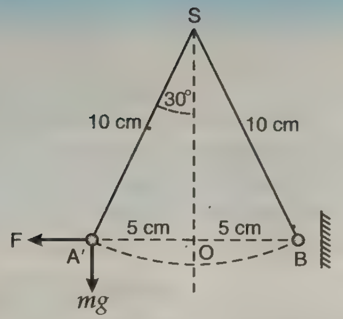

Fig. 1.37

Since cork ball is in equilibrium,

$$\frac{F}{OA'} = \frac{m g}{SO}$$

or $$F = m g \times \frac{OA'}{SO} \qquad ...(i)$$

Here, $F = \dfrac{q \times q}{(A'B)^2}$ (in cgs system),

$$SO = 10\sqrt{10^2 - 5^2} = 5\sqrt{3}\ \text{cm},$$

$m = 0{\cdot}58$ g and $g = 980$ cm s^{-2}

Setting for F, m, g, OA′ and SO in equation (*i*), we get

$$q = \mathbf{181{\cdot}16\ statC}$$

34. Suppose that the charge $-q_1$ moves around charge q_2 along circular path of radius r with speed v. The necessary centripetal force is provided by the electrostatic force of attraction between them *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 \times q_2}{r^2} = \frac{m v^2}{r}$$

or $$v = \left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 \times q_2}{m r}\right)^{1/2}$$

If T is period of revolution of the charge $-q_1$ about q_2, then

$$T = \frac{2\pi r}{v}$$

Substituting for v, we get

$$T = \sqrt{\frac{16\pi^3\varepsilon_0 m r^3}{q_1 q_2}}$$

35. Suppose that the charge q, $2q$ and Q are placed as shown in the Fig. 1.38.

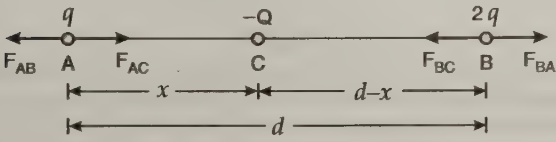

Fig. 1.38

It follows that net force on charge q and $2q$ can be zero, only if the charge Q is of opposite sign to those of charges q and $2q$. Therefore, if charges q and $2q$ are considered positive, then charge Q is negative in nature. Let the distance of charge Q (negative) from q be equal to x.

For force on charge q to be zero, $F_{AB} = F_{AC}$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q(2q)}{d^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qQ}{x^2}$$

or $$\frac{Q}{q} = \frac{2x^2}{d^2} \qquad ...(i)$$

For force on charge $2q$ to be zero, $F_{BA} = F_{BC}$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q(2q)}{d^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{(2q)Q}{(d-x)^2}$$

or $$\frac{Q}{q} = \frac{(d-x)^2}{d^2} \qquad ...(ii)$$

From equations (*i*) and (*ii*), we get

$$x = \frac{d}{\sqrt{2}+1} \quad \text{or} \quad -\frac{d}{\sqrt{2}-1}$$

36. Suppose that charge q is placed at a distance AC = r from the charge 4 Q as shown in Fig. 1.39.

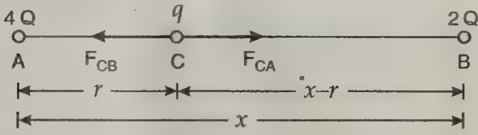

Fig. 1.39

Then, $BC = x - r$

For charge q to be in equilibrium,

$$F_{CA} = F_{CB}$$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{(4Q)q}{r^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q(2Q)}{(x-r)^2}$$

or $r = \mathbf{0{\cdot}586\ x}$ or $\mathbf{3{\cdot}414\ x}$

37. As explained in solved problem no. 1.15, for the system to be in equilibrium, the third charge Q has to be negative in nature.

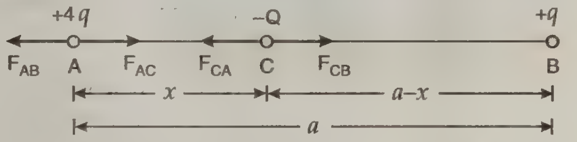

Fig. 1.40

For charge $-Q$ to be in equilibrium, $F_{CA} = F_{CB}$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{(4q)Q}{x^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{(a-x)^2} \quad \text{or} \quad x = \frac{2a}{3} \quad \text{or} \quad 2a$$

Since third charge is placed between the charges $+4q$ and $+q$,

$$x = \frac{2a}{3}$$

For charge $+4q$ to be in equilibrium, $F_{AC} = F_{AB}$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{(4q)Q}{x^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{(4q)q}{a^2} \quad \text{or} \quad Q = q\,\frac{x^2}{a^2}$$

Setting $x = 2a/3$, we get

$$Q = \frac{4}{9}q \qquad \textbf{(negative)}$$

38. Suppose that the charge Q placed at the centre of the square keeps all the charges in equilibrium [Fig. 1.41]. It follows that the charge Q has to be negative in nature.

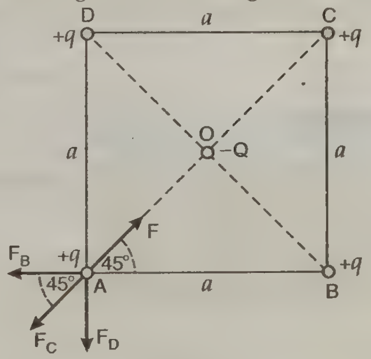

Fig. 1.41

If the net force on a charge at any corner (say A) is zero, then by symmetry it follows that the net force experienced by charges at other corners will also be zero. The charge at corner A will experience force F_B, F_C and F_D due to charges at corners B, C and D and a force F due to charge at the centre of the square. If each side of the square is of length a, then

$$AC = \sqrt{a^2 + a^2} = \sqrt{2}\, a \quad \text{and} \quad OA = \frac{1}{2}\, AC = a/\sqrt{2}$$

$$\text{Now, } F_B = F_D = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q^2}{a^2},$$

$$F_C = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q^2}{(\sqrt{2}\,a)^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q^2}{2a^2},$$

$$\text{and} \quad F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{Qq}{(a/\sqrt{2})^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{2Qq}{a^2}$$

For net force on charge at A to be zero,

$$F_B + F_C \cos 45° = F \cos 45° \qquad \text{...}(i)$$

$$\text{and} \quad F_D + F_C \sin 45° = F \sin 45° \qquad \text{...}(ii)$$

Substituting for F_B, F_C and F in equation (*i*), we get

$$Q = \left(\frac{1 + 2\sqrt{2}}{4}\right) q \quad \textbf{(negative)}$$

CHAPTER

2

Electric Field

2.01. ELECTRIC FIELD

When two charges are placed at a distance apart, they exert force on each other. Such a force is called ***action at a distance.***

Coulomb's law in electrostatics provides a method to find the magnitude of force between two point charges kept at a distance. It cannot explain the mechanism as to how two charges exert force on each other at a distance. The concept of electric field provides an explanation as to how a charge can exert force on another charge kept at a distance from it. According to field concept, the force between two charges is a two-step process.

Key point ✓

The concept of electric field provides an explanation to action at a distance.

In order to explain, consider that a charge q is present at some point in space. In the first step, it is assumed that the charge q creates something called ***electric field*** in the space around it. Likewise, charge q is called ***source charge***. In the second step, it is assumed that when another charge q_0, called ***test charge***, is placed in the electric field produced by the source charge q, the electric field exerts force on it.

Thus, *electric field due to a charge is the space around the charge, in which any other charge is acted upon by an electrostatic force.*

The electric field of a charge is the space property by virtue of which the charge modifies the space around itself. As a result, if any other charge is brought in the space around the charge, it experiences electrostatic force. It may be pointed out that the source charge does not experience any force due to electric field produced by it. The electric field due to a source charge has its own existence and is present even if there is no test charge to experience the force. Further, the electric field takes finite time to propagate. If a charge is displaced from its position, the change in electric field at a distance r will be noticed after a time r/c, where c is the speed of light.

Key point ✓

A charge does not experience any force due to electric field produced by it.

2.02. ELECTRIC FIELD INTENSITY

The electric field intensity at a point due to a source charge may be defined as the force experienced per unit positive test charge placed at that point without disturbing the source charge. The electric field intensity is also called ***strength of electric field*** or simply ***electric field.***

Key point

Usually, electric field intensity or strength of electric field is called simply electric field.

Consider that a positive test charge q_0 experiences a force $\vec{F}$, when placed at the observation point (the point, where electric field is to be determined). Then, electric field at the observation point is given by

$$\vec{E} = \frac{\vec{F}}{q_0} \qquad \text{...(2.01)}$$

In the above expression for electric field, it is assumed that when the test charge q_0 is placed at the observation point, it does not disturb the source charge. One way to ensure that test charge q_0 does not disturb the source charge is to keep its magnitude vanishingly small. If the test charge q_0 is not small, it will disturb the source charge and hence electric field at the observation point will be different from the one, had the source charge remained in its original position.

Key point ✓

To determine electric field due to a source charge, the magnitude of test charge placed at the observation point should be vanishingly small so that it does not disturb the source charge.

Therefore, *electric field intensily at a point due to a source charge may be defined as the force experienced per unit positive charge on a vanishingly small positive test charge placed at that point.*

If $\vec{F}$ is force experienced by positive test charge q_0 placed at the observation point, then electric field at that point is given by

$$\vec{E} = \underset{q_0 \to 0}{\text{Lt}} \ \frac{\vec{F}}{q_0} \qquad \text{...(2.02)}$$

Self-study Question ?

In equation (2.02), the limit $q_0 \to 0$ is against the fact that in nature, the charge less than that on an electron or a proton does not exist. How, then, this condition is justified ?

The idea of taking the limit $q_0 \to 0$ is that on placing the test charge at the observation point, the source charge will not be disturbed.

The electric field at a point is a vector quantity. From equation (2.01) or (2.02), it follows that unit of electric field in SI is **newton coulomb^{-1} (N C^{-1})**.

Key point

Another unit * of electric field is vol
metre^{-1} (V m^{-1}).

Force on a charge inside electric field. If $\vec{E}$ is electric field at a point, then by definition, a charge q placed at that point will experience a force $\vec{F}$ given by

$$\vec{F} = q\,\vec{E} \qquad ...(2.03)$$

2.03. PHYSICAL SIGNIFICANCE OF ELECTRIC FIELD

The concept of electric field is of a great significance. Two charges kept at a distance exert force on each other, which is termed as action at a distance. The concept of electric field helps us to understand the mechanism by which two charges kept at a distance exert force on each other. Further, as an alternative to Coulomb's law in electrostatics, it gives a method to find the force experienced by a charge due to another in terms of the electric field produced by it.

2.04. ELECTRIC FIELD DUE TO A POINT CHARGE

Consider that a point charge $+q$ is placed at the origin O of the co-ordinate frame. Let P be the point, where electric field due to the point charge $+q$ is to be determined [Fig. 2.01]. Let $\overrightarrow{OP} = \vec{r}$ be the position vector of the point P.

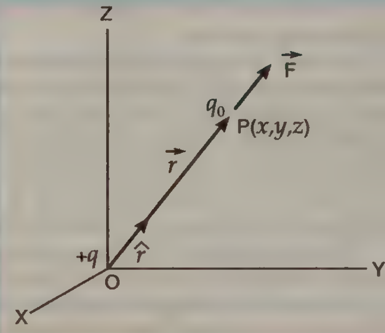

Fig. 2.01

To find electric field at point P, place a vanishingly small positive test charge q_0 at point P. According to Coulomb's law, force on the test charge q_0 due to charge q is given by

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,q_0}{r^2}\,\hat{r},$$

where $\hat{r}$ is unit vector along OP. If $\vec{E}$ is the electric field at point P, then

$$\vec{E} = \underset{q_0 \to 0}{\text{Lt}} \frac{\vec{F}}{q_0} = \underset{q_0 \to 0}{\text{Lt}} \left(\frac{1}{q_0} \cdot \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,q_0}{r^2}\,\hat{r} \right)$$

or

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\,\hat{r} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^3}\,\vec{r}, \qquad ...(2.04)$$

Key point

The electric field due to a point charge i
spherically symmetric about the charge

The magnitude of the electric field at point P is given by

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2} \qquad ...(2.05)$$

From the above expression for electric field, it follows that electric field is ***spherically symmetric*** as seen from the charge q and its magnitude decreases inversely as the square of the distance from the charge.

Representation of electric field. Let us represent the electric field due to a positive charge by associating a vector (in order to represent magnitude and direction). The magnitude and direction of the electric field at various points may be represented by arrows of suitable lengths. The points, where the electric field has large magnitude, longer arrows may be used and at the points, where the field has small magnitude, smaller arrows may be used. To be accurate, the lengths of the arrows will vary inversely as the square of the distance of the observation point from the charge. Further, the arrows will point away from the charge, in case it is a positive charge and will point into the charge, in case it is a negative charge. According to this scheme, Fig. 2.02 represents the electric field due to a positive charge, while Fig. 2.03 represents the electric field due to a negative charge.

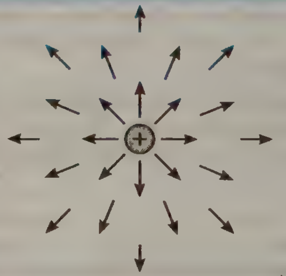

Fig. 2.02

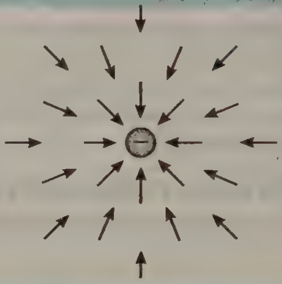

Fig. 2.03

Three components of electric field. Refer to Fig. 2.01. If (x, y, z) are the co-ordinates of point P, then

$$\vec{r} = \hat{i}\,x + \hat{j}\,y + \hat{k}\,z$$

and

$$r = |\vec{r}| = (x^2 + y^2 + z^2)^{1/2}$$

Substituting for $\vec{r}$ and r in equation (2.04), we have

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q(\hat{i}\,x + \hat{j}\,y + \hat{k}\,z)}{(x^2 + y^2 + z^2)^{3/2}} \qquad ...(2.06)$$

---

† Refer to section 3.08 of the chapter 3 on 'Electric Potential.'

Therefore, at point P, the components of electric field (magnitude only) along the three axes are given by

$$E_x = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qx}{(x^2+y^2+z^2)^{3/2}}$$

$$E_y = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qy}{(x^2+y^2+z^2)^{3/2}}$$

and $$E_z = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qz}{(x^2+y^2+z^2)^{3/2}}$$

Electric field in terms of position vectors of source charge and the observation point. Consider that the point charge q is present at point A, whose position vector is $\overrightarrow{OA} = \vec{r}\,'$ and the position vector of the observation point P is $\overrightarrow{OP} = \vec{r}$ [Fig. 2.04]. A vanishingly small positive test charge q_0 placed at point P experiences force due to charge q, which is given by

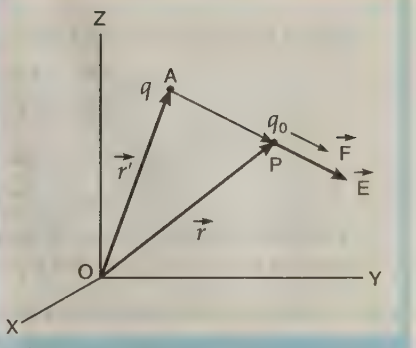

Fig. 2.04

$$\vec{F} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qq_0}{(AP)^2}\,\frac{\overrightarrow{AP}}{AP}$$

or $$\vec{F} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qq_0}{(AP)^3}\,\overrightarrow{AP} \qquad ...(2.07)$$

Here, $\overrightarrow{AP}$ is vector from charge q to the test charge q_0.

From Fig. 2.04, it follows that

$$\overrightarrow{OA} + \overrightarrow{AP} = \overrightarrow{OP}$$

or $$\overrightarrow{AP} = \overrightarrow{OP} - \overrightarrow{OA} = \vec{r} - \vec{r}\,'$$

Therefore, equation (2.07) becomes

$$\vec{F} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qq_0}{|\vec{r} - \vec{r}\,'|^3}(\vec{r} - \vec{r}\,')$$

Hence, the electric field at point P is given by

$$\vec{E} = \underset{q_0 \to 0}{\mathrm{Lt}}\ \frac{\vec{F}}{q_0}$$

or $$\vec{E} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{|\vec{r} - \vec{r}\,'|^3}(\vec{r} - \vec{r}\,') \qquad ...(2.08)$$

2.05. ELECTRIC FIELD DUE TO A DISCRETE DISTRIBUTION OF CHARGES

Electric field at a point due to discrete distribution of charges can be found by making use of ***principle of superposition of electric fields.***

Principle of superposition of electric field states that *electric field at any point due to a group of charges is equal to the vector sum of the electric fields produced by each charge individually at that point, when all other charges are assumed to be absent.*

Consider that n point charges $q_1, q_2, q_3, ..., q_n$ are distributed in space in a discrete manner. Suppose that we have to find electric field at point P due to the discrete distribution of charges. For this, place a vanishingly small positive test charge q_0 at the observation point P [Fig. 2.05]. Suppose that the charges $q_1, q_2, q_3, ... q_n$ exert forces $\vec{F}_1, \vec{F}_2, \vec{F}_3, ... \vec{F}_n$ on the test charges q_0.

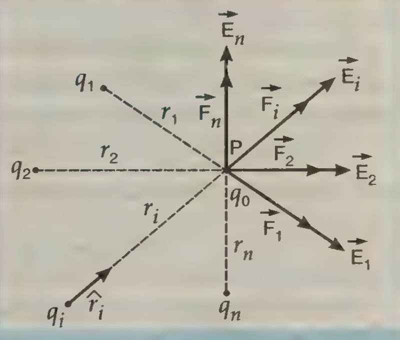

Fig. 2.05

If $\vec{F}_i$ is force due to the ith charge q_i on the test charge q_0, then

$$\vec{F}_i = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_i q_0}{r_i^2}\,\hat{r}_i,$$

where r_i is the distance of the test charge q_0 from the ith charge q_i and $\hat{r}_i$ is unit vector from charge q_i to q_0.

The electric field due to the ith charge q_i at the observation point is given by

$$\vec{E}_i = \underset{q_0 \to 0}{\mathrm{Lt}}\ \frac{\vec{F}_i}{q_0}\ \underset{q_0 \to 0}{\mathrm{Lt}}\left(\frac{1}{q_0} \times \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_i q_0}{r_i^2}\,\hat{r}_i\right)$$

or $$\vec{E}_i = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_i}{r_i^2}\,\hat{r}_i \qquad ...(2.09)$$

The electric field $\vec{E}_i$ due to the ith charge q_i at the observation point acts along the direction of the force on charge q_i. Likewise, the electric field $\vec{E}_1, \vec{E}_2, \ldots\ldots \vec{E}_n$ due to the charges $q_1, q_2, \ldots\ldots q_n$ act along the direction of the forces on the test charge due to them as shown in Fig. 2.05.

If $\vec{E}$ is the electric field due to the discrete distribution of charges, then by principle of superposition of electric fields,

$$\vec{E} = \vec{E}_1 + \vec{E}_2 + \vec{E}_3 + \ldots\ldots + \vec{E}_n = \sum_{i=1}^{n} \vec{E}_i$$

Using equation (2.09), we have

$$\vec{E} = \sum_{i=1}^{n} \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_i}{r_i^2} \hat{r}_i$$

or

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \sum_{i=1}^{n} \frac{q_i}{r_i^2} \hat{r}_i \qquad \ldots(2.10)$$

Electric field in terms of position vectors of source charges and the observation point. Suppose that n point charges $q_1, q_2, q_3, \ldots\ldots q_n$ are placed in space at the points, whose position vectors are $\vec{r}_1, \vec{r}_2, \ldots\ldots \vec{r}_n$ respectively. Let $\vec{r}_i$ be the position vector of the ith charge q_i and $\vec{r}$, the position vector of the observation point P [Fig. 2.06]. As obtained in section 2.04, the electric due to a point charge at an observation point in terms of position vectors of the charge and the observation point is given by equation (2.08). Using this equation, electric field due to charge q_i at point P is given by

$$\vec{E}_i = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_i}{|\vec{r} - \vec{r}_i|^3} (\vec{r} - \vec{r}_i)$$

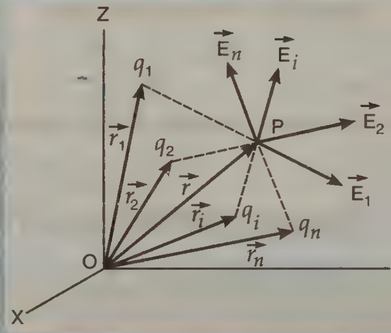

Fig. 2.06

Hence, electric field at point P due to the discrete distribution of n point charges is given by

$$\vec{E} = \sum_{i=1}^{n} \vec{E}_i$$

or

$$\vec{E}_i = \frac{1}{4\pi\varepsilon_0} \sum_{i=1}^{n} \frac{q_i}{|\vec{r} - \vec{r}_i|^3} (\vec{r} - \vec{r}_i) \qquad \ldots(2.11)$$

[illegible] ELECTRIC FIELD DUE TO A CONTINUOUS DISTRIBUTION OF CHARGES

Now, we calculate electric field due to a continuous distribution of charges in the following cases :

1. Electric field due to a line charge distribution. Refer to Fig. 1.10 of the previous chapter. Let $\vec{E}$ be electric field at location $\vec{r}$ due to the line charge distribution L having linear charge density λ.

From equation (1.21), the force on a vanishingly small test charge q_0 at location $\vec{r}$ due to the line charge distribution is given by

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot q_0 \int_L \frac{\lambda\, dl}{|\vec{r} - \vec{r}\,'|^3} (\vec{r} - \vec{r}\,')$$

Here, $\vec{r}\,'$ is position vector of the elementary portion dl of the line charge L having charge $\lambda\, dl$. Therefore, electric field at location $\vec{r}$ due to line charge distribution is given by

$$\vec{E} = \underset{q_0 \to 0}{\text{Lt}} \frac{\vec{F}}{q_0}$$

or

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \int_L \frac{\lambda\, dl}{|\vec{r} - \vec{r}\,'|^3} (\vec{r} - \vec{r}\,') \qquad \ldots(2.12)$$

2. Electric field due to a surface charge distribution. Refer to Fig. 1.11 of the previous chapter. Let $\vec{E}$ be electric field at location $\vec{r}$ due to the surface charge distribution S having surface charge density σ. From the equation (1.22), the force on a vanishingly small test charge q_0 at location $\vec{r}$ due to surface charge distribution S is given by

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot q_0 \int_S \frac{\sigma\, dS}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}')$$

Here, $\vec{r}'$ is position vector of the elementary portion dS of the surface charge distribution S having charge σ dS. Therefore, electric field at location $\vec{r}$ due to the surface charge distribution is given by

$$\vec{E} = \underset{q_0 \to 0}{\text{Lt}} \frac{\vec{F}}{q_0}$$

or
$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \int_S \frac{\sigma\, dS}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \qquad ...(2.13)$$

3. Electric field due to a volume charge distribution. Refer to Fig. 1.12 of the previous chapter. Let $\vec{E}$ be electric field at location $\vec{r}$ due to volume charge distribution V having volume charge density ρ. From the equation (1.23), the force on a vanishingly small test charge q_0 at location $\vec{r}$ due to volume charge distribution V is given by

$$\vec{F} = \frac{1}{4\pi\varepsilon_0} \cdot q_0 \int_V \frac{\rho\, dS}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}')$$

Here, $\vec{r}'$ is position vector of the elementary portion dV of the volume charge distribution V having charge ρ dV. Therefore, electric field at location $\vec{r}$ due to the volume charge distribution is given by

$$\vec{E} = \underset{q_0 \to 0}{\text{Lt}} \frac{\vec{F}}{q_0}$$

or
$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \int_V \frac{\rho\, dV}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \qquad ...(2.14)$$

Note. If charge is distributed in space continuously over a line L, over a surface S, over a volume V and also in a discrete manner in space, then total electric field at location $\vec{r}$ will be

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \left(\int_L \frac{\lambda\, dl}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') + \int_S \frac{\sigma\, dS}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \right.$$
$$\left. + \int_V \frac{\rho\, dV}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') + \sum_{\substack{\text{all} \\ \text{point charges}}} \frac{q''}{|\vec{r} - \vec{r}'|^3} (\vec{r} - \vec{r}') \right) \qquad ...(2.15)$$

2.07. ELECTRIC FIELD DUE TO A CIRCULAR LOOP OF CHARGE

Consider a circular loop of a wire of negligible thickness having radius a. Suppose that the total charge q is distributed uniformly over its circumference. Suppose the loop is placed in YZ plane, such that its centre coincides with the origin O [Fig. 2.07]. Let P be a point at a distance x from the centre of the loop on its axis OX, where electric field due to the loop is to be determined.

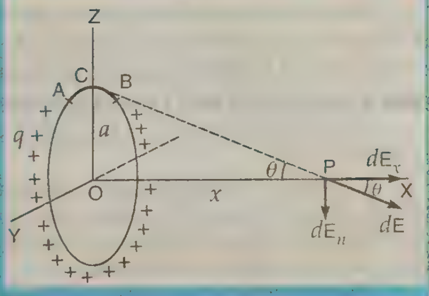

Fig. 2.07

Consider an elementary length AB of the loop of length dl. Then, charge on the elementary length AB,

$$dq = \frac{q}{2\pi a} dl$$

Let $d\vec{E}$ be electric field at point P due to charge dq on the elementary portion AB of the ring. Then, magnitude of electric field due to the elementary portion is given by

$$dE = |\vec{dE}| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{dq}{CP^2} \text{ (along CP)}$$

Now, $CP = (x^2 + a^2)^{1/2}$

Substituting for dq and CP, we have

$$dE = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,dl}{2\pi a\,(x^2 + a^2)}$$

The electric field dE due to elementary portion AB can be resolved into two components :

(*i*) dE_x along PX *i.e.* along X-axis and

(*ii*) dE_n along normal to PX. For element AB, the component dE_n will be along Z-axis and in the downward direction.

The component dE_n of dE due to various elementary portions of the circular loop will not contribute to the electric field at point P due to the whole loop. It is because of the fact that the components dE_n due to any two elementary portions of the loop located opposite to each other are equal and opposite and hence cancel out. In other words, net electric field at point P due to the whole loop of charge will be only along X-axis.

If $\vec{dE}$ makes angle θ with X-axis, then

$$dE_x = dE \cos\theta$$

In right angled triangle POC, ∠OPC = θ. Therefore,

$$\cos\theta = \frac{OP}{PC} = \frac{x}{(x^2 + a^2)^{1/2}}$$

Hence, $dE_x = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,dl}{2\pi a\,(x^2 + a^2)} \cdot \frac{x}{(x^2 + a^2)^{1/2}}$

or $$dE_x = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,x\,dl}{2\pi a\,(x^2 + a^2)^{3/2}}$$

Electric field due to whole of the circular loop is given by

$$E = \int_{\text{total loop}} dE_x = \int_{\text{total loop}} \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,x\,dl}{2\pi a\,(x^2 + a^2)^{3/2}}$$

$$= \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,x}{2\pi a\,(x^2 + a^2)^{3/2}} \int_{\text{total loop}} dl = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,x\,(2\pi a)}{2\pi a\,(x^2 + a^2)^{3/2}}$$

or $$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,x}{(x^2 + a^2)^{3/2}} \text{ (along PX)} \qquad ...(2.16)$$

Special cases. Let us evaluate the electric field due to the circular loop of the charge in the following cases :

1. ***When point P lies at centre of the loop*** : In such a case, $x = 0$. Then, from equation (2.16), it follows that

$$E = 0$$

2. ***When point P lies at a distance*** $x >> a$: In such a case, in equation (2.16), a^2 can be neglected in comparison to x^2. Then,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{x^2} \qquad \text{(along PX)}$$

It is an expression for electric field due to point charge q at a distance x from it. Therefore, *a circular loop of charge behaves as a point charge, in case observation point on its axis is at a distance quite large as compared to the dimensions (radius) of the loop.*

Key point

The electric fields due to a circular loop of charge and a point charge are identical provided the distance of the observation point from the circular loop is quite large as compared to its radius.

2.08. ELECTRIC LINES OF FORCE

An electric line of force is the path along which a unit positive charge would move, if it is free to do so.

The electric line of force points in the direction of electric field. The electric line of force may be straight or curved. In case, electric line of force is a curve, then direction of electric field at any point is given by the tangent to the line of force at that point as shown in Fig. 2.08.

The strength of the electric field at any point is measured as the number of lines of force crossing a unit area held normal to the lines of force at that point.

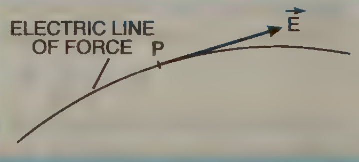

Fig. 2.08

Properties of electric lines of force. The electric lines of force have the following properties :

1. *The lines of force start from the positive charge and end at the negative charge.*

2. *The lines of force originate from or terminate at a surface always at right angles to the surface.*

3. *The lines of force do not pass through a conductor.*

It indicates that the electric field inside a conductor is always zero.

Key point ✓

Electric field inside a conductor is always zero.

4. *The lines of force never intersect each other.*

In case, two lines of force intersect at a point, then it will mean that at that point, electric field has two directions. As it is not possible, the lines of force can never ntersect each other.

5. *The relative closeness of lines of force in different regions of space gives the idea about the relative strengths of the electric field in the different regions.*

The regions, where lines of force are closer, the electric field is strong and the egions, where the lines of forces are farther apart, the field is weak.

6. *The lines of force contract longitudinally i.e. lengthwise.*

This property of lines of force leads to explain attraction between two unlike charges.

7. *The lines of force exert a lateral pressure on each other.*

This property of lines of force leads to explain the repulsion between two like charges.

Key point ✓

The property that electric lines of force contract longitudinally leads to explain the attraction between opposite charges. On the other hand, the property that electric lines of force exert lateral pressure on each other leads to explain repulsion between like charges.

Let us represent the electric field lines in the following cases :

1. ***Field lines in case of isolated point charges.*** Figs. 2.09 (*a*) and 2.09 (*b*) represent the electric field due to an isolated positive and a negative charge respectively. From the positive charge, the lines of force originate ; while in the case of negative charge, the lines of force terminate at it.

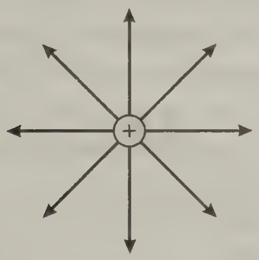

Fig. 2.09 (*a*)

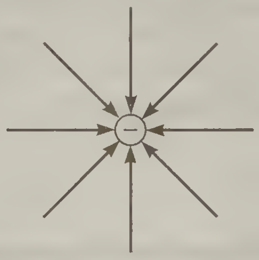

Fig. 2.09 (*b*)

2. ***Field lines in case of a system of two charges.*** Fig. 2.10 (*a*) represents field lines in case of a system of two equal and opposite charges. The field lines behave as rubber bands between the two charges and tend to contract lengthwise. Therefore, the lines of force tend to bring the two charges close to each other, which shows that opposite charges attract each other.

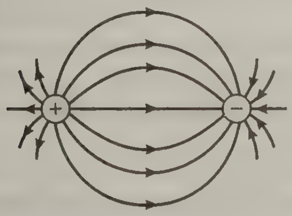

Fig. 2.10 (*a*)

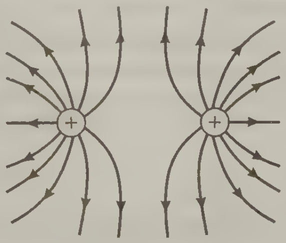

Fig. 2.10 (*b*)

Fig. 2.10 (*b*) represents field lines between two equal positive charges. The field lines seem to exert sideways pressure and hence it shows that the two like charges repel each other.

Importance of electric lines of force. The electric lines of force can be used to represent the electric field due to a point charge or a system of point charges. It may be noted that though the lines of force are imaginary, the electric field they represent s real.

2.09. ELECTRIC DIPOLE

A system of two equal and opposite charges separated by a certain distance is called an electric dipole.

Fig. 2.11 represents an electric dipole consisting of two charges $-q$ and $+q$ and separated by distance AB = $2a$. The distance AB is called length of the dipole and is a vector $\overrightarrow{2a}$, whose direction is from the charge $-q$ to charge $+q$.

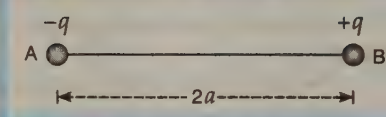

Fig. 2.11

The molecules of water, ammonia, etc behave as electric dipoles. It is because, the centres of positive and negative charges in these molecules lie at a small distance from each other.

2.10. ELECTRIC DIPOLE MOMENT

It is defined as the product of either charge and the length of the electric dipole.

It is denoted by vector $\vec{p}$, which has the same direction as that of $\overrightarrow{2a}$. Thus,

$$\vec{p} = q(\overrightarrow{2a}) \qquad \text{...(2.17)}$$

In SI, unit of electric dipole moment is **coulomb metre (C m).**

Note. If an electric dipole having electric dipole moment p (= $q \times 2a$) is an ideal one, then the charge q on either of the two poles is very very large and length $2a$ of the dipole is negligibly small, so that the product $q \times 2a$ equals the electric dipole moment of the dipole.

2.11. ELECTRIC FIELD ON AXIAL LINE OF AN ELECTRIC DIPOLE

Consider an electric dipole consisting of charges $-q$ and $+q$, separated by a distance $2a$ and placed in free space. Let P be a point on the line joining the two charges (axial line) at a distance r from the centre O of the dipole [Fig. 2.12].

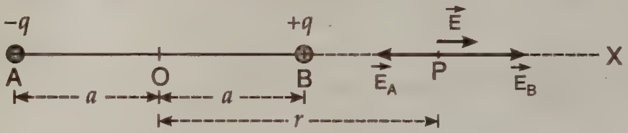

Fig. 2.12.

The electric field $\vec{E}$ at point P due to the dipole will be the resultant of the electric field $\vec{E}_A$ (due to charge $-q$ at point A) and $\vec{E}_B$ (due to charge $+q$ at point B) *i.e.*

$$\vec{E} = \vec{E}_A + \vec{E}_B$$

Now,
$$|\vec{E}_A| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{AP^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{(r+a)^2} \qquad \text{(along PA)}$$

and
$$|\vec{E}_B| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{BP^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{(r-a)^2} \qquad \text{(along PX)}$$

Obviously, $|\vec{E}_B|$ is greater than $|\vec{E}_A|$.

Since $\vec{E}_A$ and $\vec{E}_B$ act along the same line but in opposite direction, the magnitude of the electric field at point P is given by

$$E = |\vec{E}| = |\vec{E}_B| - |\vec{E}_A| \qquad \text{(along PX)}$$

or
$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{(r-a)^2} - \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{(r+a)^2}$$

$$= \frac{1}{4\pi\varepsilon_0} \cdot q \frac{(r+a)^2 - (r-a)^2}{(r^2 - a^2)^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q(4ra)}{(r^2 - a^2)^2}$$

Now, $q(2a) = p$, the magnitude of the electric dipole moment of the dipole.

$$\therefore \qquad E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{2pr}{(r^2 - a^2)^2} \text{ (along PX)} \qquad \text{...(2.18)}$$

It may be noted that direction of electric field at a point on axial line of the dipole is from charge $-q$ to $+q$ *i.e.* same as that of electric dipole moment of the dipole.

Key point

The direction of electric field due to a electric dipole at a point on its axial lin is same as that of the electric dipo moment.

When dipole is of very small length. If the dipole is of small length, such that $<< r$, then in equation (2.18), a^2 can be neglected as compared to r^2. Therefore, for n electric dipole of very small length

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{2p}{r^3} \text{ (along PX)} \qquad ...(2.19)$$

2.12. ELECTRIC FIELD ON EQUITORIAL LINE OF AN ELECTRIC DIPOLE

Consider an electric dipole consisting of charges $-q$ and $+q$ separated by a istance $2a$ and placed in free space. Let P be a point on equitorial line of the dipole ight bisector of the length of dipole) at a distance r from the centre of the dipole ig. 2.13].

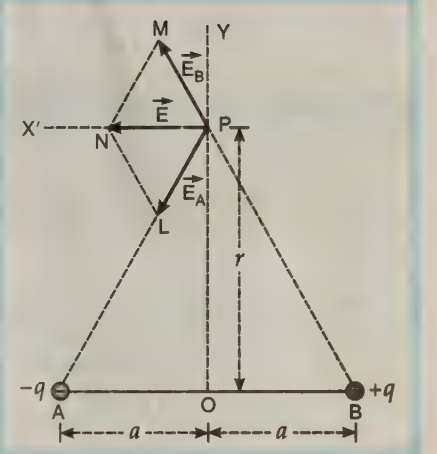

Fig. 2.13.

Let $\vec{E}_A$ and $\vec{E}_B$ be electric fields at point P due to charge $-q$ at point A and harge $+q$ at point B. Then, resultant electric field at point P is given by

$$\vec{E} = \vec{E}_A + \vec{E}_B$$

Now, $$|\vec{E}_A| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{AP^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{(r^2+a^2)} \text{ (along PA)}$$

and $$|\vec{E}_B| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{BP^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{(r^2+a^2)} \text{ (along BP)}$$

It may be noted that $\vec{E}_A$ and $\vec{E}_B$ have same magnitude. To find the resultant ectric field at point P due to the dipole, represent $\vec{E}_A$ and $\vec{E}_B$ by the two adjacent des PL and PM of a parallelogram. Then, diagonal PN of the parallelogram presents the resultant electric field $\vec{E}$ due to the dipole, which acts along PX′. The sultant electric field can also be found by using triangle law of addition of vectors. Δ PAB, $\overrightarrow{PA}$, $\overrightarrow{BP}$ and $\overrightarrow{BA}$ represent $\vec{E}_A$, $\vec{E}_B$ and $\vec{E}$ respectively. Therefore, by iangle law of addition of vectors,

$$\frac{|\vec{E}|}{BA} = \frac{|\vec{E}_A|}{PA} = \frac{|\vec{E}_B|}{BP}$$

or $$|\vec{E}| = |\vec{E}_A| \times \frac{BA}{PA} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{(r^2+a^2)} \times \frac{2a}{(r^2+a^2)^{1/2}}$$

or $$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q(2a)}{(r^2+a^2)^{3/2}}$$

Now $q(2a) = p$, the magnitude of the elecric dipole moment of the dipole. herefore,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p}{(r^2+a^2)^{3/2}} \text{ (along PX')} \qquad ...(2.20)$$

It may be noted that direction of electric field at a point on the equitorial line the dipole is from charge $+q$ to $-q$ *i.e.* opposite to the direction of electric dipole oment of the dipole.

Key point ✓

The direction of electric field due to an electric dipole at a point on its equitorial line is opposite to that of electric dipole moment.

When dipole is of very small length. If the dipole is of small length such that $<< r$, then in equation (2.20), a^2 can be neglected as compared to r^2. Therefore, for n electric dipole of very small length,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p}{r^3} \text{ (along PX')} \qquad (2.21)$$

Key point ✓

The strength of electric field at a point on axial line of an electric dipole of very small length is twice at the point at same distance on its equitorial line.

2.13. ELECTRIC FIELD AT ANY POINT DUETO AN ELECTRIC DIPOLE

Consider an electric dipole AB of small length having charge $-q$ at point A and harge $+q$ at point B. Let O be the centre of the dipole and P be any point at a istance r from its centre, where electric intensity due to the dipole is to be etermined. Let $\angle POB = \theta$ [Fig. 2.14].

The dipole moment $\vec{p}$ of the dipole can be resolved into two components :

(*i*) The component $p \cos\theta$ along OP and

(*ii*) the component $p \sin\theta$ along a direction perpendicular to OP.

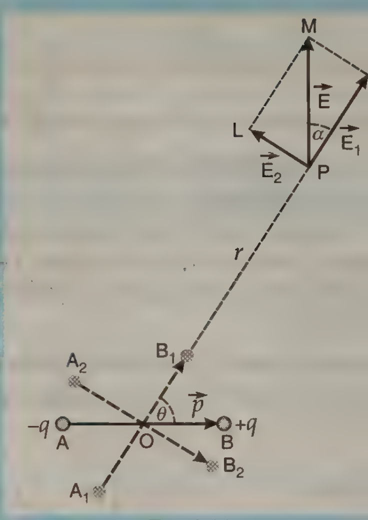

Fig. 2.14

The electric dipole AB of dipole moment *p* can be considered as to be equivalent to the combination of two electric dipoles *i.e.* one dipole $A_1 B_1$ having dipole moment $p \cos \theta$ and another electric dipole $A_2 B_2$ (placed perpendicular to $A_1 B_1$) having electric dipole moment $p \sin \theta$.

The point P lies on the axial line of dipole $A_1 B_1$. Therefore, electric field intensity at point P due to dipole $A_1 B_1$,

$$|\vec{E}_1| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{2p\cos\theta}{r^3} \quad \text{(along PK)}$$

Further, point P lies on the equitorial line of dipole $A_2 B_2$. Therefore, electric field intensity at point P due to dipole $A_2 B_2$,

$$|\vec{E}_2| = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p\sin\theta}{r^3} \quad \text{(along PL, perpendicular to PK)}$$

The resultant electric field intensity at point P,

$$\vec{E} = \vec{E}_1 + \vec{E}_2$$

or
$$E = \sqrt{|\vec{E}_1| + |\vec{E}_2|}$$

$$= \sqrt{\left(\frac{1}{4\pi\varepsilon_0} \cdot \frac{2p\cos\theta}{r^3}\right) + \left(\frac{1}{4\pi\varepsilon_0} \cdot \frac{p\sin\theta}{r^3}\right)^2}$$

$$= \frac{1}{4\pi\varepsilon_0} \cdot \frac{p}{r^3} \sqrt{4\cos^2\theta + \sin^2\theta}$$

or
$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p\sqrt{3\cos^2\theta + 1}}{r^3} \qquad \text{...(2.22)}$$

The equation (2.22) gives the magnitude of electric field intensity due to a short electric dipole at a distance *r* from its centre in a direction making an angle θ with the dipole.

To find the direction of electric field intensity due to the dipole, suppose that it makes an angle α with the direction of $\vec{E}_1$ *i.e.* with the line OK. Then, from right angled Δ PKM, we have

$$\tan\alpha = \frac{MK}{PK} = \frac{|\vec{E}_2|}{|\vec{E}_1|} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p\sin\theta}{r^3} \Big/ \frac{1}{4\pi\varepsilon_0} \cdot \frac{2p\cos\theta}{r^3}$$

or
$$\tan\alpha = \frac{1}{2}\tan\theta \qquad \text{...(2.23)}$$

The equation (2.23) can be used to find the value of angle α and hence the direction of electric field intensity due to the dipole.

2.14. ELECTRIC DIPOLE IN UNIFORM ELECTRIC FIELD

Consider an electric dipole consisting of charges $-q$ and $+q$ and of length $2a$ placed in a uniform electric field $\vec{E}$ making an angle θ with the direction of the field as shown in Fig. 2.15.

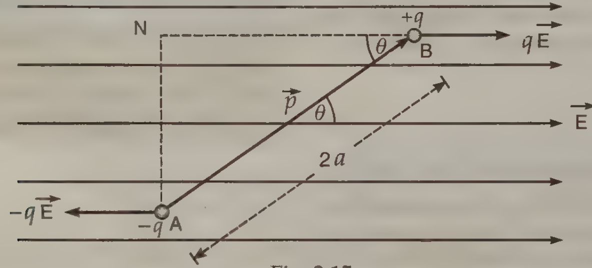

Fig. 2.15

Force on charge $-q$ at A $= -q\vec{E}$ (opposite to $\vec{E}$)

and force on charge $+q$ at B $= q\vec{E}$ (along $\vec{E}$)

Thus, electric dipole is under the action of two equal and unlike parallel forces, which give rise to a torque on the dipole. The magnitude of the torque is given by

τ = either force × perpendicular distance between the two forces

$$= q\,E\,(AN) = q\,E\,(2\,a \sin\theta) = q\,(2\,a)\,E \sin\theta$$

or $$\tau = p\,E \sin\theta \qquad ...(2.24)$$

Here, $p = q\,(2\,a)$ is electric dipole moment of the electric dipole.

The torque on the dipole tends to align it along the direction of the electric field.

Since electric dipole moment vector $\vec{p}$ is a vector from the charge $-q$ to $+q$, e equation (2.24) may be expressed as

$$\vec{\tau} = \vec{p} \times \vec{E} \qquad ...(2.25)$$

Note. 1. It may be pointed out that when dipole is placed in uniform electric eld, it experiences only a torque. Net force on the dipole is zero.

2. Torque on the dipole becomes zero, when it aligns itself parallel to the electric eld.

3. Torque on the dipole is maximum, when dipole is placed at right angles to e direction of the electric field.

$$\therefore \qquad \tau_{max} = p\,E \sin 90° = p\,E$$

Key point ✓

In a uniform electric field, an electric dipole experiences only a torque. But when the electric field is not uniform, it experiences both a torque and force.

Key point ✓

The orientation of the electric dipole along the electric field $(\vec{p} \parallel \vec{E})$ corresponds to the stable equilibrium.

SOLVED NUMERICAL PROBLEMS

ype A. On Force experienced by a charge in an electric field

Problem 2.01. Calculate the electric field strength equired to just support a water drop of mass 10^{-7} kg and aving a charge $1{\cdot}6 \times 10^{-19}$ C. *(C.B.S.E. 1999)*

Sol. Here, $m = 10^{-7}$ kg ; $q = 1{\cdot}6 \times 10^{-19}$ C

Let E be the sterngth of the electric field required to just pport the water drop. Then,

$$E\,e = m\,g$$

or $$E = \frac{m\,g}{e} = \frac{10^{-7} \times 9{\cdot}8}{1{\cdot}6 \times 10^{-19}} = \mathbf{6{\cdot}125 \times 10^{12}\ N\ C^{-1}}$$

Problem 2.02. A particle of mass 10^{-3} kg and charge 5 C is thrown at a speed 20 m s^{-1} against a uniform electric eld of strength 2×10^5 N C^{-1}. How much distance will it avel before coming to rest momentarily ?

Sol. Here, $m = 10^{-3}$ kg ; $q = 5\,\mu C = 5 \times 10^{-6}$ C ;

$$u = 20 \text{ m s}^{-1} \text{and } E = 2 \times 10^5 \text{ N C}^{-1}$$

Force on the charged particle,

$$F = q\,E = 5 \times 10^{-6} \times 2 \times 10^5 = 1 \text{ N}$$

Since the particle is thrown against the electric field, cceleration of the particle,

$$a = -\frac{F}{m} = -\frac{1}{10^{-3}} = -10^3 \text{ m s}^{-1}$$

From the relation : $v^2 - u^2 = 2\,a\,S$, we have

$$S = \frac{v^2 - u^2}{2\,a} = \frac{0^2 - 20^2}{2 \times (-10^3)} = \mathbf{0{\cdot}2\ m}$$

Problem 2.03. An oil drop of 12 excess electrons is held ationary under a constant electric field of $2{\cdot}55 \times 10^4$ V m^{-1} Millikan's oil drop experiment. The density of the oil $1{\cdot}26$ g cm^{-3}. Estimate the radius of the drop. Given that $= 9{\cdot}81$ m s^{-2}and $e = 1{\cdot}6 \times 10^{-19}$ C. *(Text Problem)*

Sol. Here, $E = 2{\cdot}55 \times 10^4$ V m^{-1}

Charge on the drop,

$$q = 12\,e = 12 \times 1{\cdot}6 \times 10^{-19}$$
$$= 1{\cdot}92 \times 10^{-18} \text{ C}$$

Force on oil drop due to electric field,

$$F_e = q\,E = 1{\cdot}92 \times 10^{-18} \times 2{\cdot}55 \times 10^4 \text{ N}$$

Force on drop due to gravity,

$$F_g = m\,g = \frac{4}{3}\pi r^3 r \rho g$$

Here, $\rho = 1{\cdot}26 \text{ g cm}^{-3} = 1{\cdot}26 \times (10^{-3} \text{ kg}) \times (10^{-2} \text{ m})^{-3}$

$$= 1{\cdot}26 \times 10^3 \text{ kg m}^{-4}$$

and $$g = 9{\cdot}81 \text{ m s}^{-2}$$

$$\therefore \qquad F_g = \frac{4}{3}\pi r^3 \times 1{\cdot}26 \times 10^3 \times 9{\cdot}81 \text{ N}$$

The drop will be held stationary, if F_g and F_e are equal and opposite *i.e.*

$$\frac{4}{3}\pi r^3 \times 1{\cdot}26 \times 10^3 \times 9{\cdot}81 = 1{\cdot}92 \times 10^{-18} \times 2{\cdot}25 \times 10^4$$

or $$r = \left(\frac{3 \times 1{\cdot}92 \times 10^{-18} \times 2{\cdot}25 \times 10^4}{4\,\pi \times 1{\cdot}26 \times 10^3 \times 9{\cdot}81}\right)^{\frac{1}{3}}$$

$$= (0{\cdot}9456 \times 10^{-18})^{1/3}$$
$$= 9{\cdot}81 \times 10^{-7} \text{ m} = \mathbf{9{\cdot}81 \times 10^{-4}\ mm}$$

Problem 2.04. A pendulum bob of mass 80 mg and carrying a charge of 2×10^{-8} coulomb is at rest in a horizontal uniform electric field of 20,000 V s^{-1}. Find the tension in thread of the pendulum and the angle it makes with the vertical. *(I.I.T. 1979)*

Sol. Consider that a pendulum bob of weight $m\,g$ and carrying a charge q is suspended in the electric field E. Suppose that it comes to rest at point A, so that it makes an angle θ with the vertical as shown in Fig. 2.16.

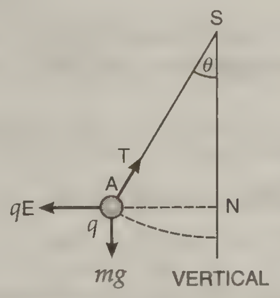

Fig. 2.16

At point A, the bob is acted upon by the following three forces :

(*i*) Weight mg acting vertically downward.

(*ii*) Tension T in the string along AS.

(*iii*) Electrostatic force q E on the bob along horizontal.

Since the bob is in equilibrium under the action of the forces mg, T and q E, these forces can be represented by the sides SN, AS and NA of the triangle ANS. Therefore,

$$\frac{mg}{SN}=\frac{qE}{NA}=\frac{T}{AS} \qquad ...(i)$$

Here, $m = 80\text{ mg} = 80 \times 10^{-6}\text{ kg}$;

$q = 2 \times 10^{-8}$ C and E = 20,000 V m^{-1}

From equation (*i*), we have

$$\frac{NA}{SN}=\frac{qE}{mg}$$

or $$\tan\theta=\frac{qE}{mg}=\frac{2\times10^{-8}\times20{,}000}{80\times10^{-6}\times9\cdot8}=0\cdot51$$

or $$\theta = 27\cdot02°$$

Again from equation (*i*), we have

$$\frac{T}{AS}=\frac{qE}{NA}$$

or $$T=\frac{qE}{NA/AS}=\frac{qE}{\sin\theta}=\frac{2\times10^{-8}\times20{,}000}{\sin(27\cdot02°)}$$

$$=\frac{2\times10^{-8}\times20{,}000}{0\cdot4543}=8\cdot8\times10^{-4}\text{ N}$$

Type B. On Electric field due to a point charge

Problem 2.05. Two point charges of 2 × 10^{-7} C and 1·0 × 10^{-7} are 1·0 cm apart. What is the magnitude of the field produced by either charge at the site of the other ? Use standard value of 1/4 π ε$_0$. (*P.S.S.C.E. 1998*)

Ans. Here, $q_1 = 2\cdot0 \times 10^{-7}$ C ; $q_2 = 1\cdot0 \times 10^{-7}$ C

and $r = 1\cdot0\text{ cm} = 10^{-2}$ m

The electric field at the site of a charge will be the electric field produced by the other charge.

Therefore, electric field due to charge q_1 at the site of q_2,

$$E_1=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{r^2}=\frac{9\times10^9\times2\cdot0\times10^{-7}}{(10^{-2})^2}=1\cdot8\times10^7\text{ N C}^{-1}$$

Also, electric field due to charge q_2 at the site of q_1,

$$E_2=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_2}{r^2}=\frac{9\times10^9\times1\cdot0\times10^{-7}}{(10^{-2})^2}=9\times10^6\text{ N C}^{-1}$$

Type C. On Electric field due to a group of charges

Problem 2.06. Two point charges of + 5× 10^{-19} C and +20 × 10^{-19} C are separated by a distance 2 m. Find the point on the line joining them at which electric field intensity is zero. (*C.B.S.E. 2001 S*)

Sol. Here, $q_1 = +5 \times 10^{-19}$ C ; $q_2 = 20 \times 10^{-19}$ C and $r = 2$ m

Suppose that the resultant electric field is zero at point O [Fig. 2.17].

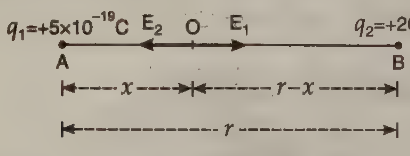

Fig. 2.17

If AO = x, then BO = $r - x = 2 - x$

Let E$_1$ and E$_2$ be electric fields at point O due to charges q_1 and q_2 respectively. Then, electric field will be zero at point O, if E$_1$ and E$_2$ are equal in magnitude and opposite in direction *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{(AO)^2}=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_2}{(BO)^2}$$

or $$\frac{5\times10^{-19}}{x^2}=\frac{20\times10^{-19}}{(2-x)^2}$$

or $$4x^2=(2-x)^2$$

or $$2x=\pm(2-x)^2$$

or $$x = 2/3\text{ m} \quad\text{or}\quad -2\text{ m}$$

Thus, electric intensity will be zero at a distanc 2/3 m from charge q_1 (towards charge q_2) or at a dista of 2 m on the other side of charge q_1.

Problem 2.07. Two point charges q_A = 3 μC q_B = – 3 μC are located 20 cm apart in vacuum. (*a*) W is the electric field at the mid-point O of the line joining the two charges ? (*b*) If a negative test charg magnitude 1·5 × 10^{-9} is placed at this point, what is force experienced by the test charge ? (*Text Probl*

Sol. Here, $q_A = 3\ \mu C = 3 \times 10^{-6}$ C ;

$q_B = -3\ \mu C = -3 \times 10^{-6}$ C and r = 20 cm = 0·2 m

Let O be the mid-point of the line AB [Fig. 2.18].

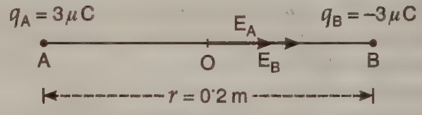

Fig. 2.18

Then, $$OA = OB = \frac{r}{2}=\frac{0\cdot2}{2}=0\cdot1\text{ m}$$

(*a*) Electric field at point O due to q_A,

$$E_A=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A}{(OA)^2}=9\times10^9\times\frac{3\times10^{-6}}{(0\cdot1)^2}$$

$= 2\cdot7 \times 10^6$ N C^{-1} (along OB)

Electric field at point O due to q_B,

$$E_B=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A}{(OB)^2}=9\times10^9\times\frac{3\times10^{-6}}{(0\cdot1)^2}$$

$= 2\cdot7 \times 10^6$ N C^{-1} (along OB)

Therefore, net electric field at point O due to charge and q_B,

$$E = E_A + E_B = 2\cdot7\times10^6 + 2\cdot7\times10^6$$

$= \mathbf{5\cdot4 \times 10^6\ N\ C^{-1}}$ (along OB)

(*b*) Force on a negative charge of magnitude 1·5 × C placed at point O,

$F = qE = 1\cdot5\times10^{-9}\times5\cdot4\times10^6 = \mathbf{8\cdot1\times10^{-3}}$ **N (along**

The force on negative charge acts in a direction oppo to that of the electric field.

Problem 2.08. Two point charges of +16μC and – are placed 8 cm apart in air. Determine the position of point at which the resultant electric field is zero.

(*P.S.S.C.E. 1*

Sol. Here, $q_A = +16\ \mu C = +16 \times 10^{-6}$ C ;

$q_B = -9\ \mu C = -9 \times 10^{-6}$ C and r = 8 cm = 0·08 m

The electric field cannot be zero at a point between two charges. It is because, the charges are of opposite si Also, the electric field cannot be zero at a point to the le charge q_A. It is because the magnitude of charge q_A is gre than that of q_B.

Suppose that the resultant electric field due to the two charges is zero at point O located to the right of charge q_B as shown in Fig. 2.19.

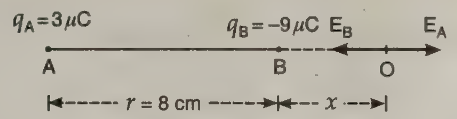

Fig. 2.19

If $OB = x$, then $OA = x + 0.08$.

The electric fields E_A and E_B due to the two charges at the point O are in opposite directions. Since resultant electric field is zero at point O, E_A and E_B are equal in magnitude *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A}{OA^2} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_B}{OB^2}$$

$$\text{or}\quad \frac{16\times10^{-6}}{(x+0.08)^2} = \frac{9\times10^{-6}}{x^2} \quad\text{or}\quad \frac{(x+0.08)}{4} = \pm\frac{x}{3}$$

$$\text{or}\quad x = 0.24\text{ m} \quad\text{or}\quad -\frac{0.24}{7}\text{ m}$$

At $x = -\frac{0.24}{7}$ m (at point to the left of point B), the magnitudes of E_A and E_B are equal but the two fields will not cancel each other. It is because at this point, both the fields will be in the same direction. Hence, electric field is zero at a point at distance **0·24 m** from the charge of – 9 μC as shown in Fig. 2.18.

Problem 2.09. Point charges 4 × 10⁻⁶ C and 2 × 10⁻⁶ C are placed at the vertices A and B of a right angled triangle ABC respectively. B is the right angle, AC = 2 × 10⁻² m and BC = 10⁻² m. Find the magnitude and direction of the resultant electric intensity at C. *(Karnataka, 1990)*

Sol. Fig. 2.20 shows the right angled triangle ABC, such

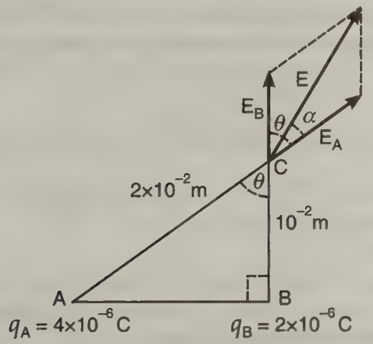

Fig. 2.20

that AC = 2 × 10⁻² m and BC = 10⁻² m. The charges of $q_A = 4\times10^{-6}$ and $q_B = 2\times10^{-6}$ C are placed at the vertices A and B respectively. Let E_A and E_B be electric intensity at point C due to charges q_A and q_B respectively. Then,

$$E_A = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A}{AC^2} = 9\times10^9\times\frac{4\times10^{-6}}{(2\times10^{-2})^2}$$

$$= 9\times10^7\text{ N C}^{-1} \qquad \text{(along AC)}$$

$$E_B = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_B}{BC^2} = 9\times10^9\times\frac{2\times10^{-6}}{(10^{-2})^2}$$

$$= 18\times10^7\text{ N C}^{-1} \qquad \text{(along BC)}$$

If θ is angle between the directions of E_A and E_B, then

$$E = \sqrt{E_A^2 + E_B^2 + 2E_AE_B\cos\theta} \qquad ...(i)$$

In right angled Δ ABC, $\angle ACB = \theta$.

$$\therefore\quad \cos\theta = \frac{BC}{AC} = \frac{10^{-2}}{2\times10^{-2}} = 0.5 \quad\text{or}\quad \theta = 60°$$

Therefore, from equation (*i*), we have

$$E = \sqrt{(9\times10^7)^2 + (18\times10^7)^2 + 2\times9\times10^7\times18\times10^7\times0.5}$$

$$= 9\times10^7\sqrt{1+4+2} = \mathbf{2.38\times10^8\ N\ C^{-1}}$$

Suppose that the resultant electric intensity E makes an angle α with the line AC. Then,

$$\tan\alpha = \frac{E_A\sin\theta}{E_A+E_B\cos\theta} = \frac{18\times10^7\sin60°}{9\times10^7+18\times10^7\times\cos60°}$$

$$= \frac{18\times10^7\times0.866}{9\times10^7+18\times10^7\times0.5} = 0.866$$

or $\alpha = \mathbf{40.9°}$

Type D. On Electric field due to an electric dipole

Problem 2.10. A dipole of length 0·1 m consists of two charges of ± 500 μC. What is its electric dipole moment ? Calculate the electric field due to the dipole at a point on the axis distant 0·2 m from one of the charges in air.

Sol. Here, $q = 500\,\mu C = 500\times10^{-6}$ C ; $2a = 0.1$ m

Therefore, electric dipole moment of the dipole,

$$p = q\,(2a) = 500\times10^{-6}\times0.1 = \mathbf{50\times10^{-6}\ C\ m}$$

The electric field at a point on axial line at a distance r from the centre of the electric dipole is given by

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2pr}{(r^2-a^2)^2}$$

Here, $p = 50\times10^{-6}$ C m ; $a = 0.1/2 = 0.05$ m

and $r = 0.2 + 0.05 = 0.25$ m

$$\therefore\quad E = 9\times10^9\times\frac{2\times50\times10^{-6}\times0.25}{(0.25^2-0.05)^2}$$

$$= \mathbf{6.25\times10^7\ N\ C^{-1}}$$

Problem 2.11. Two charges of ± 0·2 $\mu\mu$C and – 0·2 $\mu\mu$C are placed 10⁻⁶ cm apart. Calculate the electric field at an axial point at a distance of 10 cm from their mid point. Use the standard value of ε_0. *(P.S.S.C.E. 1997)*

Sol. The two charges of + 0·2 $\mu\mu$C and – 0·2 $\mu\mu$C placed 10⁻⁶ cm apart constitute an electric dipole.

Thus, $q = 0.2\ \mu\mu C = 0.2\times10^{-12}$ C ;

$2a = 10^{-6}$ cm $= 10^{-8}$ m and $r = 10$ cm $= 0.1$ m

Since $a \ll r$, the electric field on the axial line of an electric dipole is given by

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2p}{r^3}$$

Here, $p = q\,(2a) = 0.2\times10^{-12}\times10^{-8} = 0.2\times10^{-20}$ C m

Also, $\frac{1}{4\pi\varepsilon_0} = 9\times10^9$ N m² C⁻²

$$\therefore\quad E = \frac{9\times10^9\times2\times0.2\times10^{-20}}{(0.1)^3}$$

$$= \mathbf{3.6\times10^{-8}\ N\ C^{-1}}$$

Problem 2.12. Calculate the field due to an electric dipole of length 10 cm and consisting of charges of ± 100 μC at a point 20 cm from each charge.

Sol. Here, $q = 100\ \mu C = 100\times10^{-6}\text{ C} = 10^{-4}$ C

and $2a = 10$ cm $= 0.1$ m

Let P be the point at a distance of 20 cm from either charge as shown in Fig. 2.21.

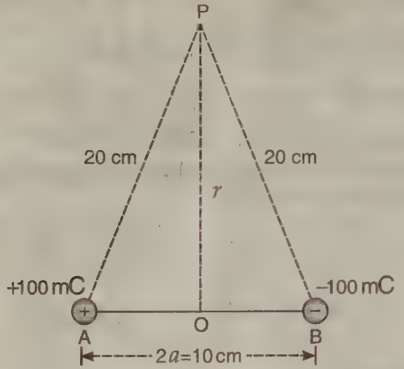

Fig. 2.21

Then, AP = BP = 20 cm = 0·2 m

Let E be electric field at point P due to the electric dipole. The point P lies at a distance OP = r on the equitorial line of the dipole. Therefore,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p}{(r^2 + a^2)^{3/2}} \quad ...(i)$$

Here, $p = q\,(2\,a) = 10^{-4} \times 0{\cdot}1$ C m

Also, $(OP^2 + OA^2)^{1/2} = AP$

or $(r^2 + a^2)^{1/2} = 0{\cdot}2$ m

Therefore from equation (*i*), we have

$$E = \frac{9 \times 10^9 \times 10^{-4} \times 0{\cdot}1}{(0{\cdot}2)^3} = \frac{9}{8} \times 10^7$$

$$= \mathbf{1{\cdot}125 \times 10^7\ N\ C^{-1}}$$

Type E. On Torque on an electric dipole

Problem 2.13. An electric dipole, when held at 30° wi respect to a uniform electric field of 10^4 N C^{-1} experienc a torque of 9 × 10^{26} N m. Calculate dipole moment of tl dipole. (*C.B.S.E. 199*

Sol. Here, E = 10^4 N C^{-1} ; $\tau = 9 \times 10^{-26}$ N m and $\theta = 3$

When electric dipole is placed at an angle θ with tl direction of the electric field, torque acting on the dipole,

$$\tau = p\,E \sin\theta$$

Therefore, electric moment of the dipole,

$$p = \frac{\tau}{E \sin\theta} = \frac{9 \times 10^{-26}}{10^4 \times \sin 30°} = \frac{9 \times 10^{-26}}{10^4 \times 0{\cdot}5}$$

$$= \mathbf{1{\cdot}8 \times 10^{-19}\ C\ m}$$

TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 2.14. A uniform electric field of strength 2 × 10^3 N C^{-1} is established between two parallel plates of length 0·1 m held horizontally at a distance 0·02 m apart. An electron is projected at a speed of 6 × 10^6 m s^{-1} making an angle 45° as shown in Fig. 2.22. The field is directed vertically upwards. Will the electron strike the either plate ? If it strikes the plate, where does it do so ?

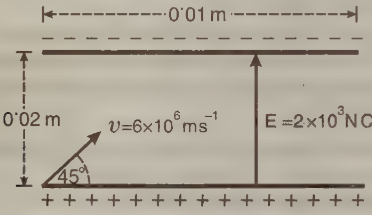

Fig. 2.22

Sol. The speed of electron can be resolved into the following two rectangular components :

(*i*) $v_x = v \cos 45° = 6 \times 10^6 \times 0{\cdot}707$

$= 4{\cdot}24 \times 10^6$ m s^{-1} (along horizontal)

As there is no force on electron along horizontal, the velocity component v_x along horizontal remains unchanged.

(*ii*) $v_y = v \sin 45° = 6 \times 10^6 \times 0{\cdot}707$

$= 4{\cdot}24 \times 10^6$ m s^{-1} (along vertical)

Since due to electric field, the electron experiences force in downward direction (opposite to its motion), the velocity component v_y along vertical goes on decreasing.

Force on electron, F = q E (downwards)

Acceleration of electron, $a = \frac{F}{m} = \frac{q\,E}{m}$

Here, $q = 1{\cdot}6 \times 10^{-19}$ C ; $m = 9{\cdot}1 \times 10^{-31}$ kg and E = 2 × 10^3 N C^{-1}

$$\therefore \quad a = \frac{1{\cdot}6 \times 10^{-19} \times 2 \times 10^3}{9{\cdot}1 \times 10^{-31}}$$

$= 3{\cdot}516 \times 10^{14}$ m s^{-2} (downwards)

For motion along vertical :

Initial velocity, $v_y = 4{\cdot}24 \times 10^{-6}$ m s^{-1} ;

$a = -\,3{\cdot}516 \times 10^{14}$ m s^{-2} and S = 0·02 m

If t is time taken by electron to reach the upper plate, th

$$S = v_y\,t + \frac{1}{2}\,a\,t^2$$

or $0{\cdot}02 = 4{\cdot}24 \times 10^6 \times t + \frac{1}{2}\,(-\,3{\cdot}516 \times 10^{14})\,t^2$

or $1{\cdot}758 \times 10^{14}\,t^2 - 4{\cdot}24 \times 10^6\,t + 0{\cdot}02 = 0$

On solving for t, we have

$t = 6{\cdot}4 \times 10^{-9}$ s

Since t has a finite real value, the electron will strike t upper plate. Suppose that it strikes the upper plate at distance x from the left end. Then,

$x = v_x \times t$

$= 4{\cdot}24 \times 10^6 \times 6{\cdot}4 \times 10^{-19} = 2{\cdot}71 \times 10^{-2}$ m = **2·71 c**

Problem 2.15. An infinite number of charges, ea equal to q are placed along X-axis at x = 1, x = 2, x = x = 8, ... and so on.

(*a*) Find electric field at the point x = 0 due to this s of charges.

(*b*) What will be the electric field, if in the above s up, the consecutive charges have opposite sign ?

(*I.I.T. 1995, 197*

Sol. Suppose that the charges $q_1, q_2, q_3, q_4, ...$ are plac at distances $r_1, r_2, r_3, r_4, ...$ from the origin. Then, electric fie at the origin due to the system of charges,

$$E = \frac{1}{4\pi\varepsilon_0}\left[\frac{q_1}{r_1^2} + \frac{q_2}{r_2^2} + \frac{q_3}{r_3^2} + \frac{q_4}{r_4^2} + ...\right]$$

(*a*) Here, $q_1 = q_2 = q_3 = q_4 = ... = q$

and $r_1 = 1, r_2 = 2, r_3 = 4, r_4 = 8, ...$

$$\therefore \quad E = \frac{1}{4\pi\varepsilon_0}\cdot\left[\frac{q}{1^2}+\frac{q}{2^2}+\frac{q}{4^2}+\frac{q}{8^2}+.....\right]$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q\left[\frac{1}{1^2}+\frac{1}{2^2}+\frac{1}{4^2}+\frac{1}{8^2}+.....\right]$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q\cdot S_\infty,$$

where $S_\infty = \frac{1}{1^2}+\frac{1}{2^2}+\frac{1}{4^2}+\frac{1}{8^2}+.....$

i.e. sum of a geometrical progression, whose first term $a = 1$ and the common ratio $r = 1/4$. Therefore,

$$S_\infty = \frac{a}{1-r} = \frac{1}{1-1/4} = \frac{4}{3}$$

Hence, $E = \frac{1}{4\pi\varepsilon_0}\cdot q \times \frac{4}{3} = \frac{q}{3\pi\varepsilon_0}$

(*b*) When the consecutive charges have opposite sign,

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\left[\frac{q}{1^2}-\frac{q}{2^2}+\frac{q}{4^2}-\frac{q}{8^2}+.....\right]$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q\left[\frac{1}{1^2}-\frac{1}{2^2}+\frac{1}{4^2}-\frac{1}{8^2}+.....\right]$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q\,\frac{1}{1-(1/4)} = \frac{q}{5\pi\varepsilon_0}$$

Proplem 2.16. Four points charges, each having a charge *q* are placed on the four corners A, B, C and D of a regular pentagon ABCDE. The distance of each corner from the centre is *a*. Find the electric field at the centre of the pentagon.

Sol. Fig. 2.23 shows a regular pentagon ABCDE with O as its centre. Four point charges, each of charge *q* are placed at the corners A, B, C and D of the pentagon.

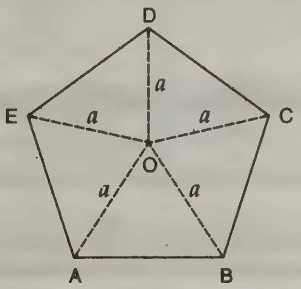

Fig. 2.23

If we put a charge *q* at the corner E also, then due to symmetric arrangement of the charges about the point O, the electric field O will be zero. It follows that electric field at point O due to the charges at four corners A, B, C and D must be equal and opposite to the field due to the charge *q* placed at corner E alone.

The electric field at point O due to the charge *q* at corner E,

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{a^2} \text{ (along EO)}$$

Therefore, electric field due to the four charges placed at corners A, B, C and D is

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{a^2} \textbf{ (along OE)}$$

Problem 2.17. In a certain region of space, electric field is along the Z-direction throughout. The magnitude of electric field is, however, not constant but increases uniformly along the positive Z-direction at the rate of 10^5 N C^{-1} m^{-1}. What are the force and torque experienced by a system having a total dipole moment equal to 10^{-7} C m in the negative Z-direction ? (*Text Problem*)

Sol. Suppose that a dipole consisting of charges $-q$ at A and $+q$ at B is placed along Z-axis, such that it has dipole moment along negative Z-direction [Fig. 2.24]

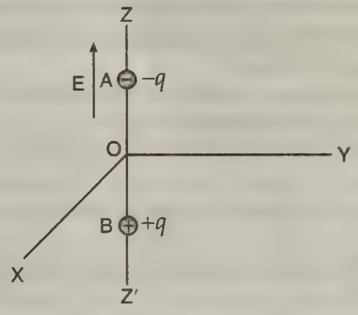

Fig. 2.24

The dipole moment of the dipole along Z-axis,

$$p_z = -10^{-7} \text{ C m}$$

The negative sign has been taken for the reason that dipole moment is along negative Z-axis.

The electric field is applied along the positive direction of Z-axis, such that $\frac{\partial E}{\partial z} = 10^5$ N C^{-1} m^{-1} (along Z-axis)

In a non-uniform electric field, the force on dipole is given by

$$F = p_x\frac{\partial E}{\partial x} + p_y\frac{\partial E}{\partial y} + p_z\frac{\partial E}{\partial z}$$

Here, $p_x = p_y = 0$ Also, $\frac{\partial E}{\partial x} = \frac{\partial E}{\partial y} = 0$

$$\therefore \quad F = p_z\frac{\partial E}{\partial z} = -10^{-7}\times 10^5 = \mathbf{-10^{-2}\ N}$$

The negative sign shows that force on the dipole is along negative Z-axis.

Since the electric dipole moment is along negative Z-axis and the electric field is along positive Z-axis, $\theta = 180°$.

Hence, torque on the dipole, $\tau = p\,E\,\sin 180° = 0$

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 2.01. Is electric field intensity a scalar or a vector quantity. Give its SI units. (*C.B.S.E. 1999 S*)

Ans. Electric field intensity is a vector quantity. Its SI unit is **N C^{-1} or V m^{-1}.**

Q. 2.02. The test charge used to measure electric field at a point should be vanishingly small. Why ?

Ans. In case, test charge is not vanishingly small, it will produce its own electric field and the measured value of electric field will be different from the actual value of electric field at that point.

Q. 2.03. Define electric field intensity at a point. *(P.S.S.C.E. 2000 ; C.B.S.E 1991)*

Ans. Refer to section 2.02.

Q. 2.04. Does an electric charge experience a force due to the field, it produces itself ?

Ans. No, an electric charge does not experience any force due to the electric field it produces itself.

Q. 2.05. Name the physical quantity, whose SI unit is newton coulomb^{-1}. *(C.B.S.E 1998)*

Ans. It is unit of electric field intensity.

Q. 2.06. A point charge q is placed at the origin. How does the electric field due to the charge vary with distance r from the origin ? *(Text Question)*

Ans. The electric field varies inversely as the square of the distance from the point charge.

Q. 2.07. Define electric dipole and electric dipole moment. *(H.S.S.C.E. 1996)*

Ans. For definitions, refer to sections 2.07 and 2.08.

Q. 2.08. What is the direction of electric dipole moment vector of an electric dipole ?

Ans. From charge $-q$ to $+q$ *i.e.* same as that of vector representing length of the electric dipole.

Q. 2.09. Give the SI unit of electric dipole moment. *(C.B.S.E. 1992)*

Ans. The unit of electric dipole moment is coulomb metre (C m).

Q. 2.10. Is it correct to write the unit of electric dipole moment as mC ?

Ans. No, it is not correct to write the unit of electric dipole moment as mC. The symbol mC represents millicoulomb *i.e.* unit of electric charge.

Q. 2.11. What is the direction of electric field at a point on axial line of an electric dipole ?

Ans. Same as that of electric dipole moment vector.

Q. 2.12. What is the direction of electric field at a point on the equitorial line of an electric dipole ?

Ans. Opposite to that of electric dipole moment vecto

Q. 2.13. What do electric lines of force represent ? *(P.S.S.C.E. 1997 S*

Ans. Electric lines of force represent the direction of th electric field.

Q. 2.14. Draw the lines of force to represent a uniforr electric field. *(C.B.S.E. 1995, 1992*

Ans. A uniform electric field is represented by paralle arrows drawn in the same direction.

Q. 2.15. Why two electric lines of force cannot intersec each other ? *(H.P.S.S.C.E. 2002 ; P.S.S.C.E. 2002, 2001 H.S.S.C.E. 2001 ; C.B.S.E. 1992*

Ans. The tangent at a point on the line of force give the direction of electric field at that point. If two lines of forc intersect each other at a point, then electric field at that poir will have two directions. As the same cannot be ture, two line of force can never intersect each other.

Q. 2.16. Does an electric dipole always experience torque, when placed in a uniform electric field ?

Ans. No. It does not experience a torque, when it i placed along the direction of electric field.

Q. 2.17. What is the net force on an electric dipol placed in a uniform electric field ?

Ans. An electric dipole does not experience any net forc in a uniform electric field.

Q. 2.18. When is the torque acting on an electric dipol maximum, when placed in uniform electric field ?

Ans. The torque is maximum, when the electric dipol is placed perpendicular to the direction of electric field.

Q. 2.19. What orientation of an electric dipole in uniform electric field corresponds to its stable equilibrium *(C.B.S.E. 2001*

Ans. When the electric dipole aligns itself along th direction of electric field ($\vec{p}$ parallel to $\vec{E}$), the torque on th dipole becomes zero. Obviously, this orientation of the electri dipole (length parallel to the electric field) corresponds to it stable equilibrium.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 2.01. Determine the magnitude of an electric field that will balance the weight of an electron. *(H.S.S.C.E. 2002, 1995)*

Ans. Let E be the electric field that will balance the weight of electron. Then,

$$q\,E = m\,g$$

Here, $q = 1{\cdot}6 \times 10^{-19}$ C ; $m = 9{\cdot}1 \times 10^{-31}$ kg

$$\therefore \quad E = \frac{m\,g}{q} = \frac{9{\cdot}1 \times 10^{-31} \times 9{\cdot}8}{1{\cdot}6 \times 10^{-19}}$$

$$= \mathbf{5{\cdot}574 \times 10^{-11}\ N\ C^{-1}} \text{ (vertically downwards)}$$

Q. 2.02. Two point electric charges of unknown magnitude and sign are placed a distance apart. The electric field intensity is zero at a point not between the charges but on the line joining them. Write two essential conditions for this to happen. *(C.B.S.E. 1997)*

Ans. 1. Both the charges can not be of same sign.

2. The observation point (where electric field intensity is zero) has to be closer to the smaller charge than to the bigge charge.

Q. 2.03. An electric dipole is formed by + 6 μC and – μC charges at 5 mm distance. Calculate the dipole momen *(H.S.S.C.E. 2001*

Ans. Here, $q = +\,6\ \mu\text{C} = \pm\,6 \times 10^{-6}$ C,

$$2\,a = 5 \text{ mm} = 3 \times 10^{-3} \text{ m}$$

Therefore, electron dipole moment,

$$p = q\,(2\,a) = 6 \times 10^{-6} \times 5 \times 10^{-3} = \mathbf{3 \times 10^{-8}\ C\ m}$$

Q. 2.04. What is an ideal electric dipole ? *(C.B.S.E. 1992*

Ans. Refer to section 2.08.

Q. 2.05. What is the ratio of the strength of electric fiel at a point on axial line and at a point at same distance o equitorial line of an electric dipole of very small length ?

Ans. Electric fields at distance r on axial line an equitorial line due to an electric dipole of very small lengt are given by

$$E_{axial} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2p}{r^3} \quad \text{and} \quad E_{equi} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{p}{r^3}$$

$$\therefore \frac{E_{axial}}{E_{equi}} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2p}{r^3} \Big/ \frac{1}{4\pi\varepsilon_0}\cdot\frac{p}{r^3} = 2$$

Q. 2.06. Define intensity of electric field at a point. At what points is the electric dipole field intensity parallel to the line joining the charges ? *(C.B.S.E. 1997)*

Or

Two point charges + q and – q are placed at a distance d apart. What are points at which the resultant field is parallel to the line joining the two charges ? *(I.I.T. 1978)*

Ans. For definition of intensity of electric field, refer to section 2.02.

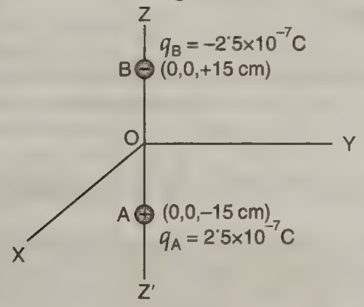
Electric field intensity due to an electric dipole is parallel to the line joining the charges at points

(*i*) on axial line of the dipole and

(*ii*) on the plane, which is right bisector of the dipole.

Q. 2.07. A system has two charges $q_A = 2{\cdot}5 \times 10^{-7}$ C and $q_B = -2{\cdot}5 \times 10^{-7}$ C located at the points A (0, 0, –15 cm) and B (0, 0, +15 cm). What is the total charge and electric dipole moment ? *(Text Question)*

Ans. The charges q_A and q_B are located at points A (0, 0, –15 cm) and B (0, 0,+15 cm). The points A and B lie on Z-axis as shown in Fig. 2.25.



Z
$q_B = -2{\cdot}5 \times 10^{-7}$ C
B
(0,0,+15 cm)
O
Y
A
(0,0,–15 cm)
$q_A = 2{\cdot}5 \times 10^{-7}$ C
X
Z′

Fig. 2.25

It follows that

AB = OA + OB = 15 + 15 = 30 cm = 0·3 m

Total charge, $q = q_A + q_B$

$= 2{\cdot}5 \times 10^{-7} + (-2{\cdot}5 \times 10^{-7}) = 0$

Electric dipole moment, p = either charge × AB

$= 2{\cdot}5 \times 10^{-7} \times 0{\cdot}3 = \mathbf{7{\cdot}5 \times 10^{-8}\ C\ m}$

The electric dipole moment is directed from B to A along Z-axis.

Q. 2.08. What is meant by the statement that the electric field of a point charge has spherical symmetry, whereas that of an electric dipole is cylindrically symmetrical ? *(H.S.S.C.E. 1996)*

Ans. The electric field due to a point charge q at a distance r from it is given by

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}$$

All such points, where electric field is equal to E (as given above) lie on the surface of a sphere of radius r, with charge q at its centre. For this reason, the electric field due to a point charge is said to be spherically symmetric.

The electric field at a distance r on the equitorial line of an electric dipole of dipole moment p and length $2a$ is given by

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{p}{(r^2+a^2)^{3/2}}$$

All such points lie on the surface of a cylinder of radius r drawn with electric dipole as its axis. For this reason, the electric field due to an electric dipole is said to be cylindrically symmetric.

Q. 2.09. What is electric line of force ? What is its importance ? *(P.S.S.C.E. 1998 S)*

Ans. An electric line of force is the path along which a unit positive charge will move inside the electric field, if it is free to do so.

The importance of electric line of force is that the tangent at any point to it gives the direction of electric field at that point. Further, the relative closeness of the electric lines of force in different regions of an electric field provides an estimate of the strength of the electric field in those regions.

Q. 2.10. Give two properties of electric lines of force. Sketch them for an isolated positive charge. *(C.B.S.E. 1992)*

Ans. For properties of electric lines of force, refer to section 2.08 and for sketch of electric lines of force for an isolated positive charge, refer to Fig. 2.09 (*a*).

Q. 2.11. Sketch the electric lines of force due to point charges (*i*) $q > 0$ and (*ii*) $q < 0$. *(C.B.S.E. 1995)*

Ans. (*i*) For a charge $q > 0$ *i.e.* for a positive charge, the electric lines of force are as shown in Fig. 2.09 (*a*).

(*ii*) For a charge $q < 0$ *i.e.* for a negative charge, the electric lines of force are is as shown in Fig. 2.09 (*b*).

It may be noted that in case of a negative charge, the lines of force terminate at the charge ; while in case of a positive charge, the lines of force originate from it.

Q. 2.12. Electric field intensity within a conductor is always zero. Why ?

Ans. The electric lines of force cannot pass through a conductor. As a result, there can be no electric field inside a conductor. Hence, electric field intensity inside a conductor is zero.

Q. 2.13. Are the field lines a reality ?

Ans. The electric field lines are purely geometrical constructions, which are used to represent electric field graphically. In other words, the electric field lines themselves are imaginary, but the electric field they represent is real.

Q. 2.14. An electric dipole with electric dipole moment 4×10^{-9} C m is aligned at 30° with the direction of a uniform electric field of magnitude 5×10^4 N C^{-1}. Calculate the magnitude of the torque acting on the dipole. *(Text Question)*

Ans. Here, $p = 4 \times 10^{-9}$ C m ; $E = 5 \times 10^4$ N C^{-1} ; $\theta = 30°$

Now, magnitude of torque acting on the dipole,

$$\tau = p\,E \sin\theta = 4 \times 10^{-9} \times 5 \times 10^4 \sin 30°$$

$$= 2 \times 10^{-4} \times \frac{1}{2} = \mathbf{10^{-4}\ N\ m}$$

TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 2.01. In defining electric field due to a point charge, the test charge has to be vanishingly small. How this condition can be justified, when we know that charge less than that on an electron or a proton is not possible ? *(Text Question)*

Ans. In the macroscopic situation, the source charges are always very large as compared to charge on an electron or a proton. Therefore, for a test charge having charge equal to that of an electron or a proton, the condition that the test charge $q_0 \to 0$ is justified for source charges of macroscopic sizes.

Q. 2.02. A ball of charge q is placed in a hollow conductive uncharged sphere. After this, the sphere is connected with earth for a short time and the ball is then removed from the sphere. The ball has not been brought into contact with the sphere.

(*a*) What charge will the sphere have after these operations ? Where and how will this charge be distributed ? (*b*) What will be the nature of the field and how will it be located ?

Ans. (*a*) The charge q will be distributed on the external surface of the sphere.

(*b*) The intensity of the electric field inside the sphere will be zero. An electric field similar to the field of the point charge q situated at the centre of the sphere will be set up outside the sphere.

Q. 2.03. Fig. 2.26 shows tracks of three charged particles crossing a uniform electrostatic field with same velocities along horizontal. Give the signs of the three charges. Which particle has the highest charge to mass ratio ? (*C.B.S.E. 2001 S ; Text Question*)

Ans. Charges 1 and 2 are deflected towards the positive plate, hence they are negatively charged particles. On the other hand, charge 3 is positively charged particle, as it gets deflected towards negative plate [Fig. 2.26].

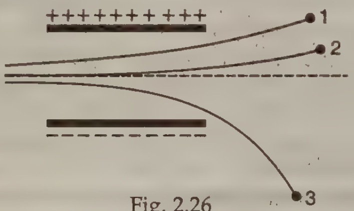


Fig. 2.26

Since all the three charged particles are crossing the electric field with same velocities, they remain under the action of electric field E (say) for the same time t. The, deflection produced in the path of a charged particle along the vertical,

$$y = u\,t + \frac{1}{2}a\,t^2$$

Now, the initial velocity of the charged particle along vertical is zero. If e is charge on a particle and m is its mass, then acceleration produced in its path,

$$a = \frac{e\,E}{m}$$

$$\therefore \qquad y = 0 \times t + \frac{1}{2}\frac{e\,E}{m}t^2 = \frac{1}{2}\frac{e\,E}{m}t^2$$

As E and t are same for all the charged particles, it follows that

$$\frac{e}{m} \propto y$$

Since the charged particle 3 suffers maximum deflection along vertical, its charge to mass ratio is highest.

Q. 2.04. A small metal ball of mass m is suspended from a thread of length l between the plates of a large plane capacitor. How will the period of oscillations of such a pendulum change, if a charge $+q$ is placed on the ball and the upper plate is (*a*) positively charged (*b*) negatively charged ?

Ans. (*a*) Fig. 2.27 shows the forces on the metal ball, whe the upper plate of the capacitor is positively charged. If E i strength of the electric field between the plates, then apparen weight of the ball

$$m\,g' = m\,g + q\,E$$

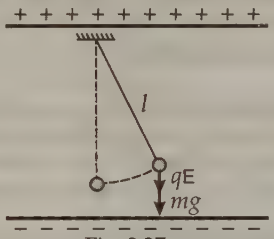

Fig. 2.27

or $\qquad g' = g + \dfrac{q\,E}{m}$

The period of oscillation of the ball is given by

$$t = 2\pi\sqrt{\frac{l}{g'}} = 2\pi\sqrt{\frac{l}{g + q\,E/m}}$$

Since $(g + q\,E/m) > g$, the time period of the ball wi decrease.

(*b*) When the upper plate of the capacitor is mad negative, then

$$m\,g' = m\,g - q\,E$$

Obviously, the period of oscillation of the ball will be

$$t = 2\pi\sqrt{\frac{l}{g - q\,E/m}}$$

Since $(g - q\,E/m) < g$, the time period of the ball wi increase.

Q. 2.05. A metal ball suspended from a long threa is placed between the plates of a capacitor as show in Fig. 2.28 (*a*). How will the oscillations of this pendulu change [Fig. 2.28 (*b*)], if the ball and the plates of th capacitor are charged ?

Ans. Suppose that the ball is given charge $+q$ and th plate A of the capacitor is made positive, while the plate B made negative [Fig. 2.28 (*b*)]. The ball will experience a forc q E (along horizontal) and force mg (along vertical).

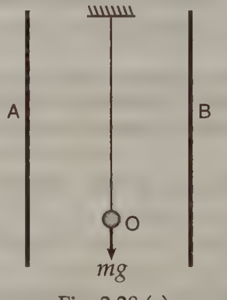

Fig. 2.28 (*a*)

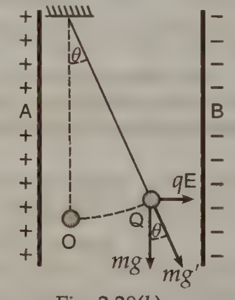

Fig. 2.28(*b*)

The equilibrium position of the ball will change from to Q. If θ is the angle, the string makes with vertical, then

$$\tan\theta = \frac{q\,E}{mg}$$

The apparent weight of the ball is given by

$$mg' = \sqrt{(mg)^2 + (q\,E)^2}$$

or $\qquad g' = \sqrt{g^2 + (q\,E/m)^2}$

The period of the oscillation of the ball is given by

$$t = 2\pi\sqrt{\frac{l}{g'}} = 2\pi\sqrt{\frac{l}{\sqrt{g^2 + (q\,E/m)^2}}}$$

Since $\sqrt{g^2 + (q\,E/m)^2} > g$, the time period of the ball **will decrease.**

Q. 2.06. A charged particle is free to move in an electric field. Will it always move along an electric line of force ? (*I.I.T. 1979*)

Ans. The charged particle may or may not move along an electric line of force. If the charged particle was initially at rest, it will move along an electric line of force. In case the charged particle had some initial velocity making certain angle with a line of force, then its resultant path will not be along the line of force.

Q. 2.07. A small test charge is released at rest at a point in an electrostatic field configuration. Will it travel along the line of force passing through that point ? (*Text Question*)

Ans. The small test charge will travel along the line of force only, if the line of force is a straight line. In case the line of force is curved, it will not move along the line of force. The reason is that line of force does not give the direction of velocity. It gives the direction, in which charge is accelerated.

Q. 2.08. An electrostatic line of force is a continuous curve *i.e.* a line of force cannot have sudden breaks. Why not ? (*Text Question*)

Ans. The tangent at a point on the electric line of force tells the direction of electric field at that point. Generally, the direction of electric field changes from point to point. Therefore, the lines of force are, generally, curved lines. Further, they are continuous curves and cannot have sudden breaks. For if it is so, it will indicate the absence of electric field at the break points.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. Explain the concept of electric field. (*P.S.S.C.E. 1990*)
2. Establish the relation between electric field strength and force. (*H.S.S.C.E. 1994 ; P.S.S.C.E. 1990*)
3. Derive an expression for electric field intensity at a point at distance *r* from a point electric charge. (*H.S.S.C.E. 1999, 1995 ; C.B.S.E. 1993*)
4. Derive an expression for the electric field intensity at any point on the axis of a uniformly charged ring. (*P.S.S.C.E. 2002*)
5. What is an electric dipole ? Define electric dipole moment and give its units. (*H.S.S.C.E. 2002*)
6. Define the term electric dipole moment. Give its units. Derive an expression for the maximum torque acting on an electric dipole, when held in a uniform electric field. (*C.B.S.E. 2002*)
7. Derive an expression for the electric field intensity at any point along the axial line of an electric dipole. (*H.P.S.S.C.E. 2002 ; P.S.S.C.E. 1999 S ; C.B.S.E. 1995*)
8. What is an electric dipole ? Calculate electric field intensity at a point on the axial line of a dipole. (*H.S.S.C.E. 2002*)
9. Define electric dipole moment. Calculate electric field intesnity at a point on the equitorial line of a dipole. (*H.S.S.C.E. 2002*)
10. Derive a relation for the intensity of electric field at an equitorial point of an electric dipole. (*H.P.S.S.C.E. 2000 ; P.S.S.C.E. 1999 S, 1997 S ; H.S.S.C.E. 1999 S*)
11. Find the electric field at a point on the right bisector line of the electric dipole. (*H.S.S.C.E. 1998 S*)
12. Find an expression for electric intensity due to a short electric dipole at any point situated along a line inclined at an angle θ to the dipole axis. (*H.S.S.C.E. 2002*)
13. Find out electric field intensity at any far point due to an electric dipole. (*H.S.S.C.E. 2001*)
14. Explain the properties of electric lines of force. (*H.S.S.C.E. 1999 S*)
15. What is meant by electric lines of force ? Give their important properties. (*H.S.S.C.E. 1992*)
16. What do electric lines of force represent ? Explain repulsion between two like charges on their basis. (*P.S.S.C.E. 1997 S*)
17. Derive an expression for the torque experienced by an electric dipole placed in a uniform electric field. (*H.P.S.S.C.E. 2002 ; H.S.S.C.E. 2001, 1998 S*)
18. Draw a labelled diagram showing an electric dipole making an angle θ with a uniform electric field E. Derive an expression for the torque experienced by the dipole. (*I.S.C.E. 1995*)
19. An electric dipole is placed in uniform field $\vec{E}$. Prove that torque $\vec{\tau}$ acting on the dipole is given by
$$\vec{\tau} = \vec{p} \times \vec{E},$$
where $\vec{p}$ is dipole strength of the dipole. (*P.S.S.C.E. 1995*)
20. Derive an expression for the torque experienced by an electric dipole placed in a uniform electric field. What is the net force acting on this electric dipole ? (*P.S.S.C.E. 2001*)
21. Find an expression for the torque experienced by an electric dipole placed in a uniform electric field. Hence, define electric dipole moment. (*H.S.S.C.E. 2002*)
22. Derive an expression for the torque acting on an electric dipole suspended freely in a uniform electric field. How will you determine the direction of torque ? (*P.S.S.C.E. 2000*)
23. An electric dipole free to move is placed in an uniform electric field. Explain with a diagram, its motion, when it is placed (*a*) parallel to the field (*b*) perpendicular to the field. (*C.B.S.E. Sample Q. Paper*)

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. Obtain expressions for electric field due to (*i*) a point charge and (*ii*) a continuous distribution of charges along a line.
2. Obtain expression for electric field due to a continuous distribution of charge over (*i*) a surface and (*ii*) a volume.
3. What is an electric dipole ? Obtain an expression for the electric field due to an electric dipole at a point on the line passing through the centre of the dipole and perpendicular to the dipole axis. (*I.S.C.E. 1994*)

4. Define electric field intensity and derive an expression for it at a point on the neutral axis of a dipole. Also determine its direction. *(P.S.S.C.E. 2000)*
5. Define electric intensity at a point and find its value at a point due to an electric dipole, when the point is on the equitorial line. *(H.S.S.C.E. 1992)*
6. Prove that for a short dipole, the intensity at a point on the axial line is twice that on the equitorial line.
7. Define electric field at a point. Two point charges q and $-q$ are placed at a distance $2\,a$ apart. Calculate the electric field at a point P situated at a distance r along the perpendicular bisector of the line joining the charges. What is the field, when $r >> a$? *(C.B.S.E. 1990)*
8. A circular loop of charge is placed in YZ-plane with it centre at origin. Find expression for electric field at a poir on X-axis.
9. A charge is distributed uniformly over a ring of radius Obtain an expression for the electric intensity $\vec{E}$ at a poir on the axis of the ring. Hence, show that for points at larg distances, the ring behaves as a point charge. *(C.B.S.E. Sample Q. Paper*
10. Show that in a uniform electric field, a dipole experience only a torque but no net force. Derive expression for th torque. *(C.B.S.E. 1999 S, 1992*

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Force experienced by a charge in an electric field

1. In the electric field shown in Fig. 2.29, the electric field lines on the left have twice the separation as that between those on the right. If the magnitude of the field at point A is 40 N C^{-1}, calculate the force experienced by a proton placed at point A. Also find the magnitude of electric field at point B. **[Ans.** $6{\cdot}4 \times 10^{-18}$ N, 20 N C^{-1}]

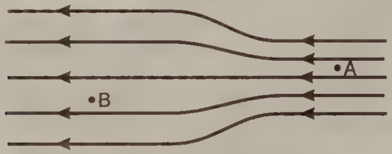

Fig. 2.29

2. Calculate the magnitude and direction of the electric field, which keeps a proton just floating. Given that mass of proton $1{\cdot}67 \times 10^{-27}$ kg, charge on proton = $1{\cdot}6 \times 10^{-19}$ C and $g = 9{\cdot}8$ m s^{-2}.
   [Ans. $1{\cdot}023 \times 10^{-7}$ N C^{-1} (vertically upward)]
3. Calculate the magnitude of electric field, which can just balance a deutron of mass $3{\cdot}2 \times 10^{-27}$ kg. Take $g = 10$ m s^{-2}. *(P.S.S.C.E. 1999)* **[Ans.** $2{\cdot}0 \times 10^{-7}$ N C^{-1}]
4. An electron above the earth is balanced by the gravitational force and the electric field of the earth. Find the electric field of the earth. **[Ans.** $5{\cdot}57 \times 10^{-11}$ N C^{-1}]
5. How many electrons should be removed from a coin of mass 1·6 g, so that it may float in an electric field of intensity 10^9 N C^{-1} directed upward. *(P.S.S.C.E. 1998 S)* **[Ans.** $9{\cdot}8 \times 10^7$]
6. An electron is released with a velocity of 5×10^6 m s^{-1} in an electric field of 10^3 N C^{-1} which has been applied so as to oppose its motion. What distance would the electron travel and how much time could it take before it is brought to rest ? **[Ans.** $7{\cdot}11 \times 10^{-2}$ m, $2{\cdot}844 \times 10^{-8}$ s]
7. An electron falls through a distance of 1·5 cm in a uniform electric field of magnitude $2{\cdot}0 \times 10^4$ N C^{-1} N [Fig. 2.30 (*a*)]. The direction of the field is reversed keeping its magnitude unchanged and a proton falls through the same distance [Fig. 2.30 (*b*)]. Compute the time of fall in each case. Given that mass of electron = $9{\cdot}1 \times 10^{-31}$ kg and mass of proto = $1{\cdot}67 \times 10^{-27}$ kg. *(Text Problem*
   [Ans. (*a*) $2{\cdot}92 \times 10^{-9}$ s (*b*) $1{\cdot}566 \times 10^{-7}$

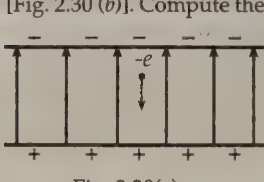

Fig. 2.30(*a*)

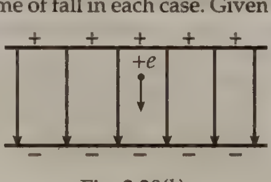

Fig. 2.30(*b*)

8. A charged particle of mass 1 g is suspended through silk thread of length 40 cm in a horizonal electric fiel of $4{\cdot}0 \times 10^4$ N C^{-1}. If the particle stays at a distance 24 cm from the wall in equilibrium, find the charge o the particle. **[Ans.** $1{\cdot}838 \times 10^{-7}$ C

Type B. On Electric field due to a group of point charges

9. Two point charges of + 20 μC and + 80 μC are place 18 cm apart. Find the position of the point, where electri field is zero.
   [Ans. at a distance 0·06 m from 20 μC charg (between the two changes) or at a distance 0·18 from 20 μC charge (on the other side of it or at 18 cm away from 20 μC on the other side of 80 μC
10. Three charges, each equal to q, are placed at the thre corners of a square of side a. Find the electric field at th fourth corner of the square.
    $$\left[\textbf{Ans. } \frac{1}{4\pi\varepsilon_0} \cdot \frac{\sqrt{9+4\sqrt{2}}\,q}{2a^2}\right.$$
11. Fig. 2.31 shows four point charges at the corners of a squar of side 2 cm. Find the magnitude and direction of th electric field at the centre O of the square, if Q = 0·02 μC
    Use $\dfrac{1}{4\pi\varepsilon_0} = 9 \times 10^9$ N m^2 C^{-2}.

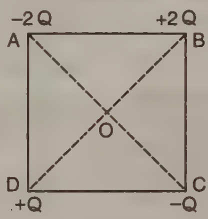

Fig. 2.31

[Ans. $9\sqrt{2} \times 10^5$ N C^{-1}, (parallel to side BA

12. Four charges $+q, +q, -q, -q$ are placed respectively at th four corners of a square of side a. Find the magnitude an direction of the electric field at the centre of the square. *(P.S.S.C.E. 1996 S*
    [Ans. $\dfrac{1}{4\pi\varepsilon_0} \cdot \dfrac{4\sqrt{2}\,q}{a^2}$, parallel to the side having charge $+q$ and $-q$ at its two ends

13. ABC is an equilateral triangle of side 5 cm. Charges of + 60 statC and – 30 statC are placed at points A and B respectively. Calculate completely the electric field at point C. Given, 1 C = 3 × 10^9 statC. [**Ans.** 6·24 × 10^4 N C^{-1} making 90° with CB and 30° with AC (when produced)]

14. ABC is a right-angled triangle, the right angle being at point B. Charges of –10·24, 11·52, + 3·24 $\mu\mu$C are placed at points A, B and C respectively. If AB = 4 cm and BC = 3 cm, calculate the magnitude and direction of the resultant electric field at the foot D of the perpendicular drawn from point B on the side AC.

[**Ans.** $180\sqrt{2}$ N C^{-1}, inclined equally with both DA and BD (when produced)]

ype C. On Electric field due to an electric dipole

15. Two point charges of 2 μC but opposite in sign are placed 10 cm apart. Calculate the electric field at a point distant 10 cm from the mid point on the axial line of the dipole. (*P.S.S.C.E. 2002*) [**Ans.** 6·4 × 10^6 N C^{-1}]

16. Two charges each of 0·1 μC but opposite in sign are 1 mm apart. What is the electric field at a point on the line joining them at a distance of 10 cm from the mid-point ? [**Ans.** 1800 N C^{-1}]

17. Two charges of + 25 × 10^{-9} coulomb and – 25 × 10^{-9} coulomb are placed 6 m apart. Find the electric field at a point 4 m from the centre of the electric dipole (*i*) on axial line (*ii*) on equitorial line.

[**Ans.** (*i*) 220·4 N C^{-1} (*ii*) 10·8 N C^{-1}]

18. Two charges ± 10 μC are placed 5·0 mm apart. Determine the electric field at (*a*) a point on the axis of the dipole 15 cm away from its centre O on the side of the positive charge, (*b*) a point 15 cm away from point O on a line passing through O and normal to the axis of the dipole.

[**Ans.** (*a*) 2·67 × 10^5 N C^{-1} ; (*b*) 1·33 × 10^5 N C^{-1}]

19. The electric field at a point on the axial line at a distance of 10 cm from the centre of an electric dipole is 3·75 × 10^5 N C^{-1} in air, while at a distance of 20 cm, the electric field is 3 × 10^4 N C^{-1}. Calculate the length of the electric dipole. [**Ans.** 0·1 m]

ype D. On Torque on an electric dipole

20. An electric dipole of dipole moment 4 × 10^{-5} C m is placed in a uniform electric field of 10^{-3} N C^{-1} making an angle of 30° from direction of field. Determine the torque exerted by the electric field on the dipole. (*H.S.S.C.E. 2002*) [**Ans.** 2 × 10^{-8} N m]

21. A dipole consisting of an electron and a proton separated by a distance 4 × 10^{-10} m is situated in an electric field of intensity 3 × 10^5 N C^{-1} at an angle of 30° with the field. Calculate the dipole moment and the torque acting on it. (Charge on an electron = 1·602 × 10^{-19} coulomb). (*Pre-degree Kerala, 1994*)

[**Ans.** 6·41 × 10^{-29} C m, 9·615 × 10^{-24} N m]

22. An electric dipole, when held at 30° with respect to an uniform electric field of 3 × 10^4 N C^{-1} experiences a torque of 27 × 10^{26} N m. Calculate the dipole moment of the dipole. (*C.B.S.E. 1996*) [**Ans.** 1·8 × 10^{-29} C m]

23. An electric dipole is placed at angle of 60° with an electric field of strength 4 × 10^{-5} N C^{-1}. It experiences a torque equal to $8\sqrt{3}$ N m. Calculate the charge on the dipole, if dipole is of length 4 cm. [**Ans.** 10^{-3} C]

MISCELLANEOUS PROBLEMS

24. A copper ball of density 8·6 g cm^{-3}, 1 cm in diameter is immersed in oil of density 0·8 g cm^{-3}. If the ball remains suspended in oil in a uniform electric field of intensity 36000 N C^{-1} acting in upward direction, what is the charge on the ball ? [**Ans.** 1·11 × 10^{-6} C]

25. A charge of 4 × 10^{-9} C is distributed uniformly over the circumference of a conducting ring of radius 0·3 m. Calculate the field intensity at a point on the axis of the ring at 0·4 m from its centre. Also, calculate the electric field at the centre of the ring. (*Roorkee 1990*)

[**Ans.** 115·2 N C^{-1}, zero]

26. A dipole consists of two charges +10 μC and –10 μC separated by a certain distance. Let they be located at x = 6·0 cm, y = 0 and x = –6·0 cm, y = 0 respectively. Calculate the field strength at a point x = 0, y = 8 cm.

[**Ans.** 1·08 × 10^7 N C^{-1}, parallel to the line joining the two charges]

27. An inclined plane making an angle of 30° with the horizontal is placed in a uniform horizontal electric field of 100 V m^{-1} as shown in Fig. 2.32. A particle of mass 1 kg and charge 0·01 C is allowed to slide down from rest from a height of 1 m. If the coefficient of friction is 0·2, find the time it will take the particle to reach the bottom. (*Roorkee, 1987*) [**Ans.** 1·337 s]

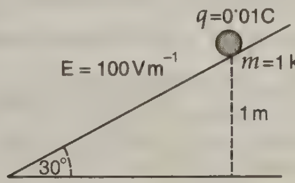

Fig. 2.32

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Force on proton at point A,

$$F = q\,E_A = 1{\cdot}6 \times 10^{-19} \times 40 = \mathbf{6{\cdot}4 \times 10^{-18}\ N}$$

Since separation between electric field lines at point B is twice as that point A, electric field at point B,

$$E_B = 40 \times \frac{1}{2} = \mathbf{20\ N\ C^{-1}}$$

2. Proceed as in solved problem no. 2.01.

3. The direction of electric field is vertically upwards and charge on deutron, $q = e = 1{\cdot}6 \times 10^{-19}$ C

Now, proceed as in solved problem no. 2.01.

4. Proceed as in solved problem no. 2.01.

5. Let n be the number of electrons removed from the coin. Then, charge on coin, $q = +\,n\,e$

Now, $q\,E = m\,g$ or $(n\,e)\,E = m\,g$

or $$n = \frac{m\,g}{e\,E} = \frac{1{\cdot}6 \times 10^{-3} \times 9{\cdot}8}{1{\cdot}6 \times 10^{-19} \times 10^{9}} = \mathbf{9{\cdot}8 \times 10^7}$$

6. Since electric field is applied so as to oppose the motion of electron,

$$a = -\frac{e\,E}{m} \text{ (retardation)}$$

$$= -\frac{1{\cdot}6 \times 10^{-19} \times 10^3}{9{\cdot}1 \times 10^{-31}} = -1{\cdot}758 \times 10^{14}\ \text{m s}^{-2}$$

Now, $u = 5 \times 10^6$ m s^{-1}, $v = 0$

Using the relation : $v^2 - u^2 = 2\,a\,S$, we get

$$S = 7{\cdot}11 \times 10^{-2}\ \mathrm{m}$$

Using the relation : $v = u + a\,t$, we get

$$t = 2{\cdot}844 \times 10^{-8}\ \mathrm{s}$$

7. Refer to Fig. 2.30 (*a*) :

Here, $a = \dfrac{eE}{m} = \dfrac{1{\cdot}6\times10^{-19}\times2{\cdot}0\times10^{4}}{9{\cdot}1\times10^{-31}}$

$$= 3{\cdot}516 \times 10^{-15}\ \mathrm{m\,s^{-2}}$$

Now, $u = 0$ and $S = 1{\cdot}5\ \mathrm{cm} = 1{\cdot}5 \times 10^{-2}\ \mathrm{m}$

Using the relation : $S = u\,t + \frac{1}{2}\,a\,t^2$, we get

$$t = 2{\cdot}92 \times 10^{-9}\ \mathrm{s}$$

Refer to Fig. 2.30 (*b*) :

Here, $a = \dfrac{eE}{m} = \dfrac{1{\cdot}6\times10^{-19}\times2{\cdot}0\times10^{4}}{1{\cdot}67\times10^{-27}}$

$$= 1{\cdot}916 \times 10^{12}\ \mathrm{m\,s^{-2}}$$

Using the relation : $S = u\,t + \frac{1}{2}\,a\,t^2$, we get

$$t = 1{\cdot}566 \times 10^{-7}\ \mathrm{s}$$

8. Let q be charge on the particle. The charged particle experiences a force q E along horizontal, which takes it away from the wall as shown in Fig. 2.33.

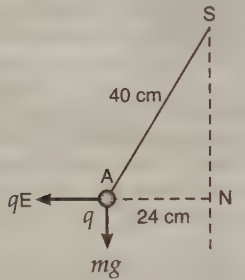

Fig. 2.33

Since the charged particle is in equilibrium,

$$\frac{qE}{AN} = \frac{mg}{SN} \quad \text{or} \quad q = \frac{mg}{E} \times \frac{AN}{SN}$$

Here, $m = 1\ \mathrm{g} = 10^{-3}\ \mathrm{kg}$, $E = 4{\cdot}0 \times 10^4\ \mathrm{N\,C^{-1}}$,

$g = 9{\cdot}8\ \mathrm{m\,s^{-2}}$, $AN = 24\ \mathrm{cm} = 0{\cdot}24\ \mathrm{m}$

and $SN = \sqrt{40^2 - 24^2} = 32\ \mathrm{cm} = 0{\cdot}32\ \mathrm{m}$

$$\therefore \quad q = \frac{10^{-3}\times9{\cdot}8\times0{\cdot}24}{4{\cdot}0\times10^{4}\times0{\cdot}32} = 1{\cdot}838 \times 10^{-7}\ \mathrm{C}$$

9. Proceed as in solved problem no. 2.06.

10. Here, AB = BC = CD = AD = a

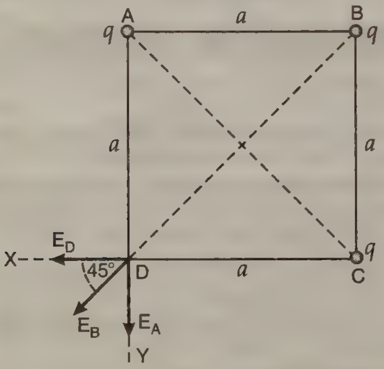

Fig. 2.34

$$\therefore \quad BD = \sqrt{a^2 + a^2} = \sqrt{2}\,a$$

Now, $E_A = E_C = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q}{a^2}$

and $E_B = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q}{(\sqrt{2}\,a)^2} = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q}{2a^2}$

Net electric field along DX,

$$E_1 = E_C + E_B\cos 45^\circ = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{a^2} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{2a^2}\times$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{a^2}\left(1 + \frac{1}{2\sqrt{2}}\right)$$

Similarly, net electric field along DY,

$$E_2 = E_A + E_B\sin 45^\circ = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{a^2}\left(1 + \frac{1}{2\sqrt{2}}\right)$$

Hence, resultant electric field at point D

$$E = \sqrt{E_1^{\,2} + E_2^{\,2}} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{\sqrt{9 + 4\sqrt{2}}\;q}{2a^2} \quad \textbf{(along BD)}$$

11. Here, AB = BC = CD = AD = 2 cm

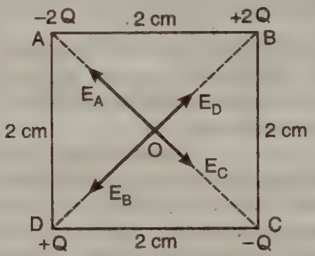

Fig. 2.35

$$\therefore AO = BO = CO = DO = \frac{\sqrt{2^2 + 2^2}}{4^2} = \sqrt{2}\ \mathrm{cm}$$

$$= \sqrt{2} \times 10^{-2}\,\mathrm{m}$$

Now, $E_A = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{2Q}{(OA)^2} = \dfrac{1}{4\pi\varepsilon_0}\cdot Q\times10^4$ (along O

$E_B = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{2Q}{(OB)^2} = \dfrac{1}{4\pi\varepsilon_0}\cdot Q\times10^4$ (along OI

$E_C = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{Q}{(OC)^2} = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{Q}{2}\times10^4$ (along O

and $E_D = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{Q}{(OB)^2} = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{Q}{2}\times10^4$ (along OB

Net electric field along OA,

$$E_1 = E_A - E_C = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Q}{2}\times10^4$$

Also, net electric field along OD,

$$E_2 = E_B - E_D = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Q}{2}\times10^4$$

Hence, resultant electric field at point O,

$$E = \sqrt{E_1^{\,2} + E_2^{\,2}} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Q}{\sqrt{2}}\times10^4$$

(parallel to side I

Now, $Q = 0{\cdot}02\ \mu\mathrm{C} = 0{\cdot}02 \times 10^6$

$$\therefore \quad E = 9\times10^9\cdot\frac{0{\cdot}02\times10^{-6}\times10^4}{\sqrt{2}}$$

$$= \mathbf{9\sqrt{2}\times10^5\ N\,C^{-1}}\ \textbf{(parallel to side BA)}$$

12. Proceed as in problem no. 11.

13. Here, AB = BC = CA = 5 cm = 5×10^{-2} m

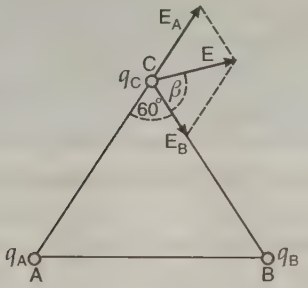

Fig. 2.36

$$q_A = 60 \text{ statC} = \frac{60}{3\times 10^9} = 2 \times 10^{-8}\text{ C},$$

$$q_B = -30 \text{ statC} = -10^{-8}\text{ C}$$

Now, $E_A = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q_A}{AC^2} = 7.2 \times 10^4 \text{ N C}^{-1}$

(along AC, when produced)

and $E_B = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q_B}{BC^2} = 3.6 \times 10^4 \text{ N C}^{-1}$ (along CB)

Electric fields E_A and E_B are inclined at angle 180° – 60° *i.e.* 120°.

Therefore, resultant electric field at point C,

$$E = \sqrt{{E_A}^2 + {E_B}^2 + 2\,E_A\,E_B \cos 120^\circ} = \mathbf{6.24 \times 10^4\ N\ C^{-1}}$$

If resultant electric field makes an angle β with CB, then

$$\tan\beta = \frac{E_A \sin 120^\circ}{E_B + E_A \cos 120^\circ} = \infty \quad \text{or} \quad \beta = 90^\circ$$

14. The charges $q_A = -10.24 \times 10^{-12}$ C, $q_B = 11.52 \times 10^{-12}$ C and $q_C = 3.24 \times 10^{-12}$ C are placed at corners A, B and C of right angled Δ ABC as shown in Fig. 2.37. The point D is foot of the perpendicular drawn from point B on the side AC.

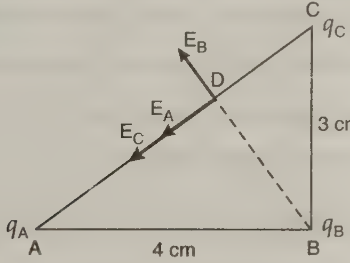

Fig. 2.37

Since AB = 4 cm and BC = 3 cm, it can be obtained that

AC = 5 cm, CD = 1.8 cm,

AD = 3.2 cm and BD = 2.4 cm

Now, $E_A = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q_A}{AD^2} = 90 \text{ N C}^{-1}$ (along DA)

$E_B = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q_B}{BD^2} = 180 \text{ N C}^{-1}$

(along BD, when produced)

and $E_C = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q_C}{CD^2} = 90 \text{ N C}^{-1}$ (along DA)

The resultant electric field at point D,

$$E = \sqrt{(E_A + E_C)^2 + {E_B}^2} = \mathbf{180\sqrt{2}\ N\ C^{-1}}$$

Since $(E_A + E_C)$ and E_B are equal, the resultant electric field will be inclined equally with DA and BD (when produced).

15. Proceed as in solved problem no. 2.10.

16. Proceed as in solved problem no. 2.11.

17. Here, $q = 25 \times 10^{-9}$ C, $2a = 6$ m, $r = 4$ m

$\therefore \quad p = q\,(2a) = 25 \times 10^{-9} \times 6 = 1.5 \times 10^{-7}$ C m

Now, $E_{axial} = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{2pr}{(r^2 - a^2)^2} = \mathbf{220.4\ N\ C^{-1}}$

and $E_{equi} = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{p}{(r^2 + a^2)^{3/2}} = \mathbf{10.8\ N\ C^{-1}}$

18. Here, $q = 10\ \mu$C $= 10^{-5}$ C, $2a = 5.0$ mm $= 5 \times 10^{-3}$ m, $r = 15$ cm $= 0.15$ m,

$\therefore \quad p = q\,(2a) = 10^{-5} \times 5 \times 10^{-3} = 5 \times 10^{-8}$ C m

For an electric dipole of short length ($2a << r$),

$$E_{axial} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2p}{r^3} = \frac{9\times 10^9 \times 2 \times 5 \times 10^{-8}}{(0.15)^3}$$

$$= \mathbf{2.67 \times 10^5\ N\ C^{-1}}$$

and $E_{equi} = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{p}{r^3} = \dfrac{9\times 10^9 \times 5 \times 10^{-8}}{(0.15)^3}$

$$= \mathbf{1.33 \times 10^5\ N\ C^{-1}}$$

19. $E_{axial} = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{2pr}{(r^2 - a^2)^2}$

In first case :

When $r = 10$ cm $= 0.1$ m, $E_{axial} = 3.75 \times 10^5$ N C^{-1}

$$\therefore \quad 3.75 \times 10^5 = 9 \times 10^9 \times \frac{2p \times 0.1}{[(0.1)^2 - a^2]^2} \qquad ...(i)$$

In second case :

When $r = 20$ cm $= 0.2$ m, $E_{axial} = 3 \times 10^4$ N C^{-1}

$$\therefore \quad 3 \times 10^4 = 9 \times 10^9 \times \frac{2p \times 0.2}{[(0.2)^2 - a^2]^2} \qquad ...(ii)$$

Solving equations (*i*) and (*ii*), we obtain

$a = 0.5$ m

Therefore, length of dipole, $2a = 0.5 \times 2 = \mathbf{0.1\ m}$

20. $\tau = p\,E \sin\theta = 4 \times 10^{-5} \times 10^{-3} \sin 30^\circ = \mathbf{2 \times 10^{-8}\ N\ m}$

21. $p = q\,(2a) = 1.602 \times 10^{-19} \times 4 \times 10^{-10} = \mathbf{6.41 \times 10^{-29}\ C\ m}$

and $\tau = p\,E \sin\theta = 6.41 \times 10^{-29} \times 3 \times 10^5 \times \sin 30^\circ$

$= \mathbf{9.615 \times 10^{-24}\ N\ m}$

22. Proceed as in solved problem no. 2.13.

23. To find p, proceed as in solved problem no. 2.13.

Then, $q = \dfrac{p}{2a}$

24. Apparent weight of the ball = $m\,g$ – upthrust

$$= \frac{4}{3}\pi r^3 (\rho - \sigma)\,g = \frac{4}{3}\pi \times (0.5)^3 \times (8.6 - 0.8) \times 980$$

$= 4002.4$ dyne $= 4.0024 \times 10^{-2}$ N

Let q be charge on the ball. As the ball remains suspended,

$q\,E$ = apparent weight of the ball

or $q = \dfrac{\text{apparent weight}}{E} = \dfrac{4.0024 \times 10^{-2}}{36000} = \mathbf{1.11 \times 10^{-6}\ C}$

25. Now, $E = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q\,x}{(x^2 + a^2)^{3/2}}$

Here, $a = 0.3$ m, $x = 0.4$ m and $q = 4 \times 10^{-9}$ C

$$\therefore \quad E = \frac{9 \times 10^9 \times 4 \times 10^{-9} \times 0.4}{[(0.4)^2 + (0.3)^2]^{3/2}} = \mathbf{115.2\ N\ C^{-1}}$$

Electric field at the centre of the ring is zero.

26. Here, $q = 10\ \mu$C $= 10^{-5}$ C, $2a = 6 - (-6) = 12$ cm $= 0.12$ m,

$r = 8$ cm $= 0.08$ m

Now, $E_{equi} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p}{(r^2+a^2)^{3/2}}$

$$= \frac{9\times10^9\times1\cdot2\times10^{-6}}{[(0\cdot08)^2+(0\cdot06)^2]^{3/2}} = \mathbf{1{\cdot}08\times10^7\ N\ C^{-1}}$$

27. The various forces act on the charged particle as shown in Fig. 2.38.

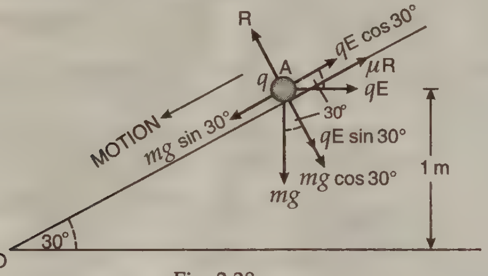

Fig. 2.38

Net force on the charged particle along the inclined pla in downward direction,

$F = m\,g \sin 30° - \mu\,R - q\,E \cos 30°$

Now, $R = m\,g \cos 30° + q\,E\ \sin 30°$

$\therefore\quad F = m\,g\,(\sin 30° - \mu \cos 30°) - q\,E\,(\cos 30° + \mu \sin 3$

$= 1 \times 9{\cdot}8\ (0{\cdot}5 - 0{\cdot}2 \times 0{\cdot}866)$

$- 0{\cdot}01 \times 100\ (0{\cdot}866 + 0{\cdot}2 \times 0$

$= 2{\cdot}237\ N$

Acceleration of the particle along the inclined plane,

$$a = \frac{F}{m} = \frac{2\cdot237}{1} = 2\cdot237\ m\,s^{-2}$$

Let OA = S. Then, $\sin 30° = \frac{AQ}{OA}$

or $\quad S = OA = \frac{AQ}{\sin 30°} = 2\ m$

Initial velocity of charged particle, $u = 0$

Using the relation : $S = u\,t + \frac{1}{2}\,a\,t^2$, we have

$t = \mathbf{1{\cdot}337\ s}$

CHAPTER

3

Electric Potential

3.01. CONSERVATIVE NATURE OF ELECTROSTATIC FORCE

A force is said to be conservative, if work done by the force between two points is ndependent of the path followed between the two points. Further, work done by a onservative force along a closed path is always zero.

All the forces, which obey inverse square law are conservative in nature. Therefore, gravitational and electrostatic forces are conservative forces. Hence, work done by electrostatic force between two points is same for all the paths between the wo points. Also, the work done by electrostatic force along a closed path is zero.

Key point

The electrostatic and gravitational forces are conservative in nature.

3.02. INDEPENDENCE OF LINE INTEGRAL OF ELECTRIC FIELD ON THE NATURE OF PATH BETWEENTWO POINTS

The electric field possesses one basic property that *the line integral of electric field etween two points is independent of the path followed between the two points.*

This property of electric field leads to the concept of electric potential, an lectrical parameter of great importance. As we shall learn, electric field can also e represented in terms of electric potential. Before doing so, let us first prove that ine integeral of electric field between two points is independent of the path followed etween the two points.

Consider a point charge + q located at the origin O of the co-ordinate frame OXYZ as shown in Fig. 3.01. The electric field due to the point charge will be directed long the dotted arrows *i.e.* radially outwards from the point charge + q. Suppose hat AB is any path (straight or curved) between two points A and B in the electric ield of the point charge + q, such that OA = r_A and OB = r_B. Further, suppose that is any point on the path AB and $\vec{E}$ is electric field due to the point charge + q at his point. Suppose that distance of point P from the point charge + q is OP = r. Let $\overrightarrow{PQ} = \vec{dl}$ be infinitesimally small displacement along the path AB. Since electric ield $\vec{E}$ gives measure of force on a unit positive charge placed at point P,

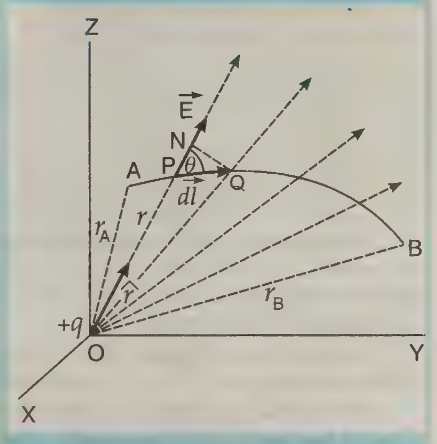

Fig. 3.01

$\vec{E} \cdot \vec{dl}$ = work done by the electric field $\vec{E}$ in moving a unit positive charge from point P to Q *i.e.* through $\overrightarrow{PQ}\ (= \vec{dl})$

Hence, $\int_A^B \vec{E} \cdot \vec{dl}$ = work done by the electric field $\vec{E}$ in moving a unit positive charge from the point A to B

Here, $\int_A^B \vec{E} \cdot \vec{dl}$ is called *the line integral of the electric field $\vec{E}$ between points A and B.*

Let us now find the value of integral $\int_A^B \vec{E} \cdot \vec{dl}$.

The electric field at point P due to point charge + q located at the point O is iven by

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\,\hat{r},$$

vhere $\hat{r}$ is unit vector along the line OP. If θ is angle between the directions of $\vec{E}$ and $\vec{dl}$, then

$$\vec{E}\cdot\vec{dl} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\,\hat{r}\cdot\vec{dl} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\,(1)\,(dl)\cos\theta$$

or $$\vec{E}\cdot\vec{dl} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\,dl\cos\theta \qquad \text{...(3.01)}$$

From point Q, drop QN perpendicular to OP. Then, from right angled Δ PNQ, we have

$$PN = PQ\cos\theta = dl\cos\theta$$

Further, as PN (the projection of $\vec{dl}$ along the line OP) is in the direction of increasing r, the distance PN is taken as $+dr$. Therefore,

$$dl\cos\theta = dr$$

Setting $dl\cos\theta = dr$ in equation (3.01), we have

$$\vec{E}\cdot\vec{dl} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\,dr$$

Hence, $$\int_A^B \vec{E}\cdot\vec{dl} = \int_A^B \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\,dr = \frac{1}{4\pi\varepsilon_0}\cdot q\int_A^B r^{-2}\,dr \qquad \text{...(3.02)}$$

The values of r corresponding to points A and B are r_A and r_B respectively. Therefore, in equation (3.02), corresponding to the limits from A to B, the proper limits of integration are from r_A to r_B. Likewise, equation (3.02) becomes

$$\int_A^B \vec{E}\cdot\vec{dl} = \frac{1}{4\pi\varepsilon_0}\cdot q\int_{r_A}^{r_B} r^{-2}\,dr = \frac{1}{4\pi\varepsilon_0}\,q\left|\frac{r^{-1}}{-1}\right|_{r_A}^{r_B} = \frac{1}{4\pi\varepsilon_0}\cdot q\left|-\frac{1}{r_B}-\left(-\frac{1}{r_A}\right)\right|$$

or $$\int_A^B \vec{E}\cdot\vec{dl} = \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r_A}-\frac{1}{r_B}\right) \qquad \text{...(3.03)}$$

Key point

Line integral of electric field between tw
points is independent of the path followe
between the points.

The equation (3.03) gives the value of line integral of the electric field between two points A and B along the path AB shown in Fig. 3.01. It follows that the expression depends only on the distances of the end points A and B (*i.e.* r_A and r_B) and not upon the path AB.

Hence, *the line integral of the electric field between two points is same for all the paths between the two points i.e. it is independent of the path followed between the two points.*

The following points may be noted about the line integral of an electric field :

1. Line integral of an electric field along a closed path is zero. Consider a closed path AP_1BP_2A in the electric field of point charge $+q$ [Fig. 3.02]. Then, line integral of electric field between points A and B along path P_1 is given by

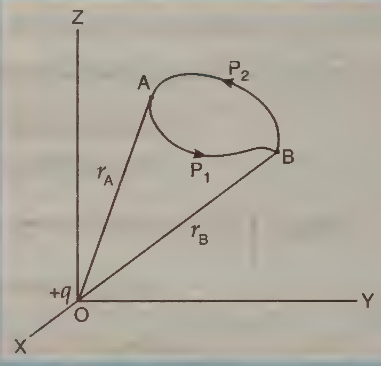

Fig. 3.02

$$\underset{\text{along path } P_1}{\int_A^B \vec{E}\cdot\vec{dl}} = \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r_A}-\frac{1}{r_B}\right)$$

Similarly, line integral of electric field between points B and A along path P_2 is given by

$$\underset{\text{along path } P_2}{\int_B^A \vec{E}\cdot\vec{dl}} = \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r_B}-\frac{1}{r_A}\right)$$

$$\therefore \quad \underset{\text{along path } P_1}{\int_A^B \vec{E}\cdot\vec{dl}} + \underset{\text{along path } P_2}{\int_B^A \vec{E}\cdot\vec{dl}} = \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r_A}-\frac{1}{r_B}\right) + \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r_B}-\frac{1}{r_A}\right)$$

or $$\underset{\text{along path } P_1}{\int_A^B \vec{E}\cdot\vec{dl}} + \underset{\text{along path } P_2}{\int_B^A \vec{E}\cdot\vec{dl}} = 0$$

Key point

Line integral of electric field along
closed path is zero.

The L.H.S. of the above equation represents sum of the line integrals of electric field from point A to B along path P_1 and then from point B to A along path P_2. Mathematically, this sum of two integrals is denoted as $\oint \vec{E}\cdot\vec{dl}$ *i.e.* line integral of the electric field along the closed path AP_1BP_2A. Therefore, the above equation may be expressed as

$$\oint \vec{E} \cdot \vec{dl} = 0 \qquad \text{...(3.04)}$$

Hence, *the line integral of an electric field along a closed path in an electric field is always zero.*

2. Line integral of electric field between two points is equal to work done by electric field in moving a unit positive test charge between the two points in the electric field. The electric field at a point measures the force experienced by a unit positive test charge placed at that point. Therefore,

$$\vec{E} \cdot \vec{dl} = \text{work done by electric field in moving a unit positive test charge through } \vec{dl}$$

Hence, work done by the electric field in moving a unit positive test charge from point A to B,

$$W = \int_A^B \vec{E} \cdot \vec{dl} \qquad \text{...(3.05)}$$

Key point ✓

$\int_A^B \vec{E} \cdot \vec{dl}$ represents work done by electric field $\vec{E}$ in moving a unit positive cnarge from point A to B.

Obviously, work done in moving a unit positive test charge against the electric field from point A to B

$$W = -\int_A^B \vec{E} \cdot \vec{dl} \qquad \text{...(3.06)}$$

Key point ✓

$-\int_A^B \vec{E} \cdot \vec{dl}$ represents work done by an external agent to move a unit positive charge against the electrostatic force exerted on the charge due to electric field $\vec{E}$.

3. Line integral of electric field is same for all the paths between two points only in case of static electric fields. The equation (3.03) does not hold for electric fields due to moving charges.

3.03. CONCEPT OF ELECTROSTATIC POTENTIAL DIFFERENCE AND POTENTIAL FROM THE LINE INTEGRAL OF ELECTRIC FIELD

Consider a point charge $+q$ located at the origin O of the co-ordinate frame OXYZ as shown in Fig. 3.03. The electric field due to charge $+q$ will be directed along the dotted arrows *i.e.* radially outwards from the charge $+q$. Let A and B be two points in the electric field of charge $+q$ and AB be any arbitrary path between the two points.

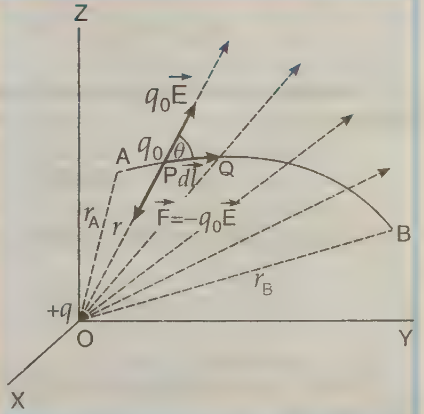

Fig. 3.03

The electrostatic potential difference between two points B and A in an electric field is defined as the amount of work done per unit positive test charge in moving it from point A to B against the electrostatic force due to the electric field.

If V_A and V_B are electrostatic potentials at points A and B in the electric field of point charge $+q$ and W_{AB} is work done in moving a vanishingly small positive test charge q_0, then by definition

$$V_B - V_A = \frac{W_{AB}}{q_0} \qquad \text{...(3.07)}$$

Suppose that at any instant, the test charge q_0 is at point P, such that $OP = r$. Let $\vec{E}$ be electric field at point P due to the source charge $+q$ placed at point O.

The force on test charge q_0 due to electric field of source charge $= q_0 \vec{E}$

To keep the charge in equilibrium, an external force $\vec{F} = -q_0 \vec{E}$ has to be applied on the test charge so as to balance the electrostatic force due to the source charge. Further, suppose that the test charge q_0 is moved through an infinitesimally small displacement $\vec{PQ} = \vec{dl}$. Then, small work done in moving the test charge from point P to Q,

$$dW = \vec{F} \cdot \vec{dl} = (-q_0 \vec{E}) \cdot \vec{dl}$$

Therefore, work done in moving the test charge q_0 from point A to B is given by

$$W_{AB} = \int_A^B dW = \int_A^B (-q_0 \vec{E}) \cdot \vec{dl} = -q_0 \int_A^B \vec{E} \cdot \vec{dl}$$

The work done per unit positive test charge in moving it from point A to B,

$$\frac{W_{AB}}{q_0} = -\int_A^B \vec{E} \cdot \vec{dl} \qquad ...(3.08)$$

From equations (3.07) and (3.08), we have

$$V_B - V_A = -\int_A^B \vec{E} \cdot \vec{dl} \qquad ...(3.09)$$

Hence, *the electrostatic potential difference between two points B and A in an electric field is equal to the negative of the line integral of the electric field between the points A and B.*

Key point

Potential difference between two points B and A in an electric field $\vec{E}$ is equal to negative of line integral of $\vec{E}$ from point A to B.

To define and express electrostatic potential at a point in an electric field, consider that point A is located at infinity. The electrostatic potential at a point at infinite distance from charge $+q$ is zero. As such, the electrostatic potential difference between point B and point A (at infinity) will be just the electrostatic potential at point B. Likewise, electrostatic potential at a point is defined as below :

The electrostatic potential at a point in an electric field is defined as the amount of work done per unit positive test charge in moving it from infinity to that point against the electrostatic force due to the electric field.

If V_B is electrostatic potential at point B in the electric field of point charge $+q$ and $W_{\infty B}$ is work done in moving a vanishingly small positive charge q_0 from infinity to point B, then by definition

$$V_B = \frac{W_{\infty B}}{q_0} \qquad ...(3.10)$$

By proceeding as above, it can be obtained that work done in moving the positive test charge q_0 from infinity to point B,

$$W_{\infty B} = -q_0 \int_\infty^B \vec{E} \cdot \vec{dl}$$

Therefore, work done per unit positive test charge in moving it from infinity to point B,

$$\frac{W_{\infty B}}{q_0} = -\int_\infty^B \vec{E} \cdot \vec{dl} \qquad ...(3.11)$$

From equations (3.10) and (3.11), we have

$$V_B = -\int_\infty^B \vec{E} \cdot \vec{dl} \qquad ...(3.12)$$

Thus, *electrostatic potential at a point in an electric field is equal to the negative of the line integral of the electric field between infinity and that point.*

Key point

Potential at a point in an electric field $\vec{E}$ is equal to line integral of $\vec{E}$ between infinity and that point.

3.04. EXPRESSION FOR ELECTRIC POTENTIAL DIFFERENCE

The electrostatic potential difference between two points in an electric field may be defined as the amount of work done per unit positive test charge in moving it from one point to the other (without acceleration) against the electrostatic force due to the electric field.

Since potential difference is defined as the work done per unit positive charge between two points, it is a ***scalar quantity.***

Consider that a point charge $+q$ is placed at point O and points A and B are any two points in the electric field of the point charge $+q$. Let r_A and r_B be distances of points A and B from the point charge $+q$ [Fig. 3.04]. Suppose that V_A and V_B are electric potentials at the points A and B respectively.

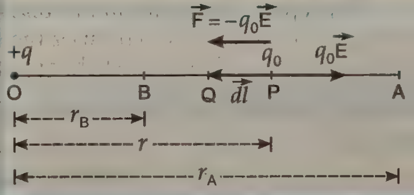

Fig. 3.04

If W_{AB} is the amount of work done in moving a vanishingly small positive test charge q_0 from point A to B, then

$$V_B - V_A = \frac{W_{AB}}{q_0} \qquad ...(3.13)$$

Suppose that at any instant, the test charge is at point P. If $\vec{E}$ is electric field at point P due to charge $+q$ placed at point O, then

force on the test charge q_0 due to the electric field of the source charge $= q_0 \vec{E}$

To move the test charge against this electrostatic force without acceleration, the external force to be applied is given by

$$\vec{F} = -q_0\,\vec{E}$$

Suppose the test charge is moved through infinitesimally small displacement $\overrightarrow{PQ} = \vec{dl}$, then small work done to move the test charge from point P to Q,

$$dW = \vec{F}\,.\,\vec{dl} = (-q_0\,\vec{E})\,.\,\vec{dl} = -q_0\,E\,dl\cos 180° = q_0\,E\,dl$$

As the test charge is moved from point A to B, the distance r decreases in the direction of displacement $\vec{dl}$. For this reason, the distance dl is taken as $-dr$. Therefore,

$$dW = q_0 E\,(-dr) = -q_0\,E\,dr$$

Now, electric field at point P due to the charge $+q$,

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}$$

$$\therefore \qquad dW = -q_0\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\right)dr = -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q\,q_0}{r^2}\,dr$$

Hence, work done in moving the test charge q_0 from point A to B is given by

$$W_{AB} = \int_A^B dW = \int_{r_A}^{r_B} -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q\,q_0}{r^2}\,dr = -\frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\int_{r_A}^{r_B} r^{-2}\,dr$$

$$= -\frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left|\frac{r^{-1}}{-1}\right|_{r_A}^{r_B} = \frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left|\frac{1}{r}\right|_{r_A}^{r_B}$$

or

$$W_{AB} = \frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left(\frac{1}{r_B}-\frac{1}{r_A}\right) \qquad ...(3.14)$$

From equations (3.13) and (3.14), we have

$$V_B - V_A = \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r_B}-\frac{1}{r_A}\right) \qquad ...(3.15)$$

Unit of electrostatic potential difference. The SI unit of potential difference is **volt (V).** In SI, work and charge are measured in joule and coulomb respectively. Therefore, from equation (3.13), the SI unit of potential difference is also given by

$$\mathbf{1\ volt\ (V)} = \frac{\mathbf{1\ joule}}{\mathbf{1\ coulomb}} = \mathbf{1\ joule\ coulomb^{-1}\ (J\,C^{-1})}$$

The electrostatic potential difference between two points is said to be 1 volt, if 1 joule of work is done in moving a charge of 1 coulomb from one point to the other (without acceleration) against the electrostatic force due to electric field.

Note. If the source charge is located at a point, whose position vector is $\vec{r}\,'$, then

$$V_B - V_A = \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{|\vec{r}_B - \vec{r}\,'|}-\frac{1}{|\vec{r}_A - \vec{r}\,'|}\right) \qquad ...(3.16)$$

Key point

Electric potential is a characteristic of electric field. It does not matter, whether a charge is placed in the electric field or not.

3.05. ELECTRICAL POTENTIAL DUE TO A POINT CHARGE

The electrostatic potential at a point in an electric field may be defined as the amount of work done per unit positive test charge in moving it from infinity to that point (without acceleration) against the electrostatic force due to the electric field.

It is a ***scalar quantity.***

Consider a point charge $+q$ placed at point O. Suppose that V_A is electric potential at point A, whose distance from the source charge $+q$ is r_A[Fig. 3.05].

If $W_{\infty A}$ is work done in moving a vanishingly small positive test charge q_0 from infinity to point A, then

$$V_A = \frac{W_{\infty A}}{q_0} \qquad ...(3.17)$$

Suppose that at any instant, the test charge is at point P. The electric field $\vec{E}$ due to the charge $+q$ exerts force $q_0\,\vec{E}$ on the test charge placed at point P. The test

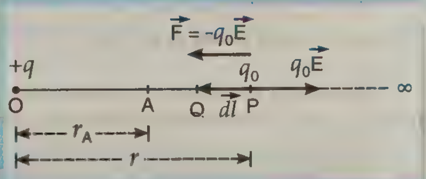

Fig. 3.05.

charge can be moved against this force without acceleration by applying an external force $\vec{F} = -q_0\,\vec{E}$ on it. If the test charge q_0 is moved through infinitesimally small displacement $\overrightarrow{PQ} = \vec{dl}$, then small work done is given by

$$dW = \vec{F}\,.\,\vec{dl} = (-q_0\,\vec{E})\,.\,\vec{dl} = -q_0\,E\,dl\cos 180^\circ = q_0\,E\,dl$$

or
$$dW = -q_0\,E\,dr$$

Here, as discussed in last section, dl has been taken as $-dr$, as the distance r decreases in the direction of $\vec{dl}$.

Since
$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\text{, we have}$$

$$dW = -q_0\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}\right)dr = -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q\,q_0}{r^2}\,dr$$

Hence, work done in moving the test charge from infinity to point A is given by

$$W_{\infty A} = \int_{\infty}^{A} dW = \int_{\infty}^{r_A} -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q\,q_0}{r^2}\,dr = -\frac{1}{4\pi\varepsilon_0}\,q\,q_0\int_{\infty}^{r_A} r^{-2}\,dr$$

$$= -\frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left|\frac{r^{-1}}{-1}\right| = \frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left|\frac{1}{r}\right|_{\infty}^{r_A}$$

$$= -\frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left(\frac{1}{r_A}-\frac{1}{\infty}\right) = \frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left(\frac{1}{r_A}-0\right)$$

or
$$W_{\infty A} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_0}{r_A} \qquad ...(3.18)$$

From equations (3.17) and (3.18), we have

$$V_A = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r_A}$$

In case, the distance of point A is from the charge $+q$ is denoted by r (in place of r_A), then subscript A may be dropped. If V denotes the electrostatic potential at any point at distance r from the charge $+q$, then

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r} \qquad ...(3.19)$$

Unit of electrostatic potential. The unit of electric potential is also **volt (V).**

1 volt (V) = 1 joule coulomb^{-1} (J C^{-1})

The electrostatic potential at a point is said to be 1 volt, if 1 joule of work is done in moving a charge of 1 coulomb from infinity to that point (without acceleration) against the electrostatic force due to electric field.

Note. If the source charge is located at a point, whose position vector is $\vec{r}\,'$, then

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{|\vec{r}-\vec{r}\,'|} \qquad ...(3.20)$$

3.06. ELECTRIC POTENTIAL DUE TO A SYSTEM OF CHARGES

Let us now find electrostatic potential at a point P due to a group of point charges $q_1, q_2, q_3 .... q_n$ lying at distances $r_1, r_2, r_3 .... r_n$ from point P [Fig. 3.06]. The electrostatic potential at point P due to these charges is found by calculating electrostatic potential at point P due to each individual charge, considering the other charges to be absent and then adding up these electrostatic potentials algebraically.*

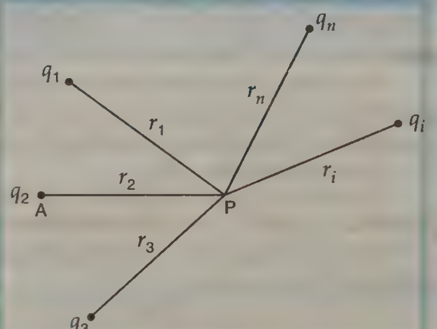

Fig. 306.

The electrostatic potential at point P due to charge q_1, when other charges are considered absent,

$$V_1 = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{r_1}$$

Similarly, electrostatic potentials at point P due to the individual charges $q_2, q_3, ... q_n$ (when other charges are absent) are given by

$$V_2 = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_2}{r_2}\,;\ V_3 = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_3}{r_3}\,;\,.........;\ V_n = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_n}{r_n}$$

---

*Because, electrostatic potential is a scalar quantity.

Hence, electrostatic potential at point P due to the group of n point charges,

$$V = V_1 + V_2 + V_3 + \ldots\ldots + V_n$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{r_1} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_2}{r_2} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_3}{r_3} + \ldots\ldots + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_n}{r_n}$$

$$= \frac{1}{4\pi\varepsilon_0}\left(\frac{q_1}{r_1} + \frac{q_2}{r_2} + \frac{q_3}{r_3} \ldots\ldots + \frac{q_n}{r_n}\right)$$

or

$$V = \frac{1}{4\pi\varepsilon_0}\sum_{i=1}^{n}\frac{q_i}{r_i} \qquad \ldots(3.21)$$

Key point

Electric potential at a point due to a group of charges is equal to algebraic sum of the potentials at that point due to individual charges.

Note. 1. In case the electric charges $q_1, q_2, q_3, \ldots\ldots q_n$, are located at points, whose sition vectors are $\vec{r}_1, \vec{r}_2, \vec{r}_3, \ldots\ldots \vec{r}_n$, then electrostatic potential at a point at ation $\vec{r}$ can be found by making use of equation (3.20). Therefore, electrostatic tential due to the discrete distribution of charges is given by

$$V = \frac{1}{4\pi\varepsilon_0}\sum_{i=1}^{n}\frac{q_i}{|\vec{r} - \vec{r}_i|} \qquad \ldots(3.22)$$

Here, $\vec{r}_i$ is position vector of the ith charge q_i.

2. It can be easily deduced that electrostatic potential at location $\vec{r}$

(*a*) due to the line charge distribution L is given by

$$V = \frac{1}{4\pi\varepsilon_0}\int_L \frac{\lambda\, dl}{|\vec{r} - \vec{r}\,'|} \qquad \ldots(3.23)$$

(*b*) due to the surface charge distribution S is given by

$$V = \frac{1}{4\pi\varepsilon_0}\int_S \frac{\sigma\, dS}{|\vec{r} - \vec{r}\,'|} \qquad \ldots(3.24)$$

(*c*) and due to the volume charge distribution V is given by

$$V = \frac{1}{4\pi\varepsilon_0}\int_V \frac{\rho\, dV}{|\vec{r} - \vec{r}\,'|} \qquad \ldots(3.25)$$

Here, in equations (3.23), (3.24) and (3.25), λ, σ and ρ are linear charge density, face charge density and volume charge density respectively and $\vec{r}\,'$ is position ctor of the elementary portion dl, dS or dV of the linear, surface or volume charge tribution.

3.07. ELECTRIC POTENTIAL AT ANY POINT DUE TO AN ELECTRIC DIPOLE

Consider an electric dipole AB having charge $-q$ at point A and charge $+q$ point B. Let O be the centre of the dipole and P be any point at a distance r m its centre, where electric potential due to the dipole is to be determined. Let POB = θ [Fig. 3.07].

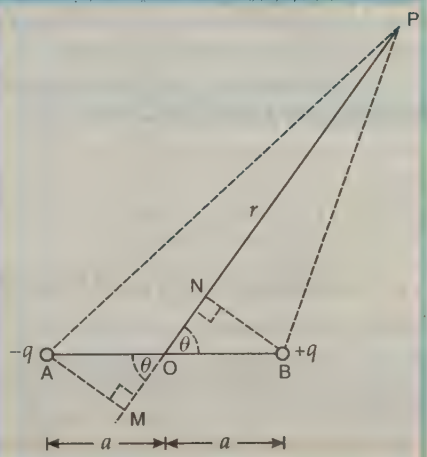

Fig. 3.07

The potential at point P due to charge $-q$,

$$V_1 = -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{PA}$$

and the potential at point P due to charge $+q$,

$$V_2 = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{PB}$$

Therefore, net potential at point P due to the dipole,

$$V = V_1 + V_2 = -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{PA} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{PB}$$

or

$$V = \frac{1}{4\pi\varepsilon_0}\cdot q\left[\frac{1}{PB} - \frac{1}{PA}\right] \qquad \ldots(3.26)$$

To find PB and PA, draw BN perpendicular to OP and AM perpendicular to PO after producing it. From right angled Δ AMO, we have

$$\cos\theta = \frac{\text{OM}}{\text{OA}} = \frac{\text{OM}}{a} \quad \text{or} \quad \text{OM} = a\cos\theta$$

In case the length of the dipole is very small as compared to distance r, then

$$\text{PA} \approx \text{PM} = \text{PO} + \text{OM} = r + a\cos\theta$$

Similarly, it can be obtained that

$$\text{PB} = r - a\cos\theta$$

Substituting for PA and PB in equation (3.26), we have

$$\text{V} = \frac{1}{4\pi\varepsilon_0}\cdot q\left[\frac{1}{r - a\cos\theta} - \frac{1}{r + a\cos\theta}\right] = \frac{1}{4\pi\varepsilon_0}\cdot q\left[\frac{r + a\cos\theta - r + a\cos\theta}{r^2 - a^2\cos^2\theta}\right]$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q \cdot \frac{2a\cos\theta}{(r^2 - a^2\cos^2\theta)}$$

Since $q\,(2\,a) = p$, the electric dipole moment of the dipole, the above equation becomes

$$\text{V} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{p\cos\theta}{(r^2 - a^2\cos^2\theta)} \qquad \text{...(3.27)}$$

The equation (3.27) gives electric potential due to the dipole at a distance r from its centre in a direction making an angle θ with the dipole.

Special cases. Let us find the electric potential due to the dipole in the following two cases :

1. *When point P lies on the axial line of the dipole.* In such a case, $\theta = 0°$ and $\cos\theta = \cos 0° = 1$

Therefore, equation (3.27) gives

$$\text{V}_{axial} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{p}{(r^2 - a^2)} \qquad \text{...(3.28)}$$

In case $a << r$, then

$$\text{V}_{axial} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{p}{r^2} \qquad \text{...(3.29)}$$

2. *When point P lies on the equatorial line of the dipole.* In such a case, $\theta = 90°$ and $\cos\theta = \cos 90° = 0$

Therefore, equation (3.27) gives

$$\text{V}_{equi} = 0 \qquad \text{....(3.30)}$$

Key point

Electric potential at a point on equitoria line of an electric dipole is always zero.

Note. For derivation of expressions for electric potential due to a dipole at a point on its axial and equitorial lines independently, refer to SAQ 3.10 and SAQ 3.11 respectively.

3.08. ELECTRIC FIELD AS GRADIENT OF POTENTIAL

Consider a point charge $+q$ placed at point O. Suppose that V and V + dV are electrostatic potentials at points P and Q, whose distances from the charge $+q$ are r and $r - dr$ respectively [Fig. 3.08].

If dW is the amount of work done in moving a vanishingly small positive test charge q_0 from point P to Q, then

$$(\text{V} + d\text{V}) - \text{V} = \frac{d\text{W}}{q_0}$$

$$\text{or} \qquad d\text{V} = \frac{d\text{W}}{q_0} \qquad \text{...(3.31)}$$

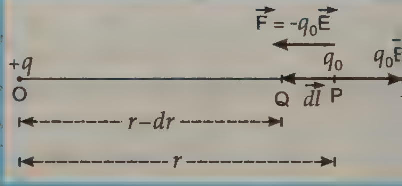

Fig. 3.08

If $\vec{E}$ is electric field at point P due to charge $+q$ placed at point O, then the test charge q_0 experiences a force equal to $q_0\vec{E}$ and the external force required to move the test charge (without acceleration) against the electric field $\vec{E}$ is given by

$$\vec{F} = -q_0\vec{E}$$

Therefore, work done to move the test charge through an infinitesimally small displacement $\overrightarrow{PQ} = \vec{dl}$ is given by

$$d\text{W} = \vec{F}\cdot\vec{dl} = (-q_0\vec{E})\cdot\vec{dl} = -q_0\,\text{E}\,dl\cos 180° = q_0\,\text{E}\,dl$$

As the distance r decreases in the direction of $\vec{dl}$, the distance dl is taken as $-dr$. erefore, the above equation becomes

$$dW = -q_0 E\, dr$$

or $$\frac{dW}{q_0} = -E\, dr \qquad ...(3.32)$$

From equations (3.31) and (3.32), we have

$$dV = -E\, dr$$

or $$E = -\frac{dV}{dr} \qquad ...(3.33)$$

Therefore, *electric field at a point is equal to the negative gradient of the electrostatic tential at that point.* The negative sign indicates that the direction of $\vec{E}$ is always the direction of decrease of electric potential.

Unit of potential gradient. In SI, the unit of potential gradient is **volt etre^{-1} (V m^{-1}).**

3.09. EQUIPOTENTIAL SURFACES

Any surface, which has same electrostatic potential at every point, is called an uipotential surface.

The equipotential surfaces can be drawn through any region, in which there electric field. If all the points at same potential in the electric field are joined, an uipotential surface is obtained.

Since all points of an equipotential surface are at same potential, no work is ne in moving a test charge between any two points on the equipotential surface. us, if $\vec{E}$ is electric field at a point on the equipotential surface and a test charge is moved through a displacement $\vec{dl}$ on the surface, then

$$q_0\, \vec{E} \cdot \vec{dl} = 0 \qquad \text{or} \qquad \vec{E} \cdot \vec{dl} = 0$$

. $\vec{E}$ is perpendicular to $\vec{dl}$. Since $\vec{dl}$ is along the equipotential surface, electric eld $\vec{E}$ must be perpendicular to it. In other words, electric lines of force are always rpendicular to the equipotential surface.

3.10. PROPERTIES OF EQUIPOTENTIAL SURFACES

The following properties are associated with the equipotential surfaces :

1. No work is done in moving a test charge over an equipotential surface. t A and B be two points on an equipotential surface [Fig. 3.09]. If a positive test arge q_0 is moved from point A to B, then work done in moving the test charge is lated to electrostatic potential difference between the two points as

$$V_B - V_A = \frac{W_{AB}}{q_0}$$

Since the two points A and B are on the same equipotential surface,

$$V_B - V_A = 0$$

$$\therefore \qquad \frac{W_{AB}}{q_0} = 0 \qquad \text{or} \qquad W_{AB} = 0$$

Hence, no work is done in moving a test charge between two points on an uipotential surface.

2. The electric field is always at right angles to the equipotential surface. Since ork done in moving a test charge between two points on an equipotential surface zero, the displacement of the test charge and the force applied on it must be rpendicular to each other. Since displacement is along the equipotential surface, d force on test charge if $q_0 \vec{E}$, the electric field ($\vec{E}$) must be at right angles to the uipotential surface.

3. The equipotential surfaces help to distinguish regions of strong field from ose of weak field. We know that

$$E = -\frac{dV}{dr} \qquad \text{or} \qquad dr = -\frac{dV}{E}$$

Key point

Electric field at a point is equal to the negative gradient of potential at that point and is directed in the direction of decrease of potential.

Watch out !

Electric potential is a scalar quantity but electric potential gradient is a vector quantity !

Self-test Question

Show that electric field may also be measured as **volt metre^{-1} (V m^{-1})**

Key point

Electric field is always perpendicular to an equipotential surface and as a result, work done in moving a charge between two points on an equipotential surface is zero.

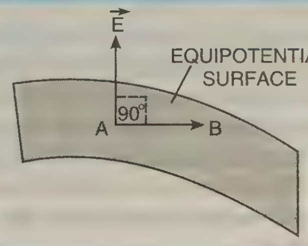

Fig. 3.09

Key point

In the regions, where equipotential surfaces are relatively closer, the electric field is stronger and vice-versa.

For same change in value of dV *i.e.* dV=constant, we have

$$dr \propto \frac{1}{E}$$

i.e. the spacing between the equipotential surfaces will be lesser in the regions, where the electric field is stronger and vice-versa. Therefore, *the equipotential surfaces are closer together, where the electric field is stronger and farther apart, where the field is weaker.*

4. The equipotential surfaces tell the direction of the electric field. Again,

$$E = -\frac{dV}{dr}$$

The negative sign tells that electric field is directed in the direction of electric potential with distance. Therefore, direction of electric field is from the equipotential surfaces which are closer to each other to those which are more and more away from each other, provided such surfaces having been drawn for same change in value of dV.

5. No two equipotential surfaces can intersect each other. In case, two equipotential surfaces intersect each other, then at their point of intersection, there will be two values of electric potential. As it is not possible, the two equipotential surfaces can not intersect each other.

3.11. TO DRAW EQUIPOTENTIAL SURFACES

The various properties of equipotential surfaces discussed in last section can be used to draw and study the equipotential surfaces in different situations. Let us now study the equipotential surfaces in the following cases :

1. For a uniform electric field. In a uniform electric field, the strength and direction of the field is same at every point inside it. A uniform electric field is represented by a set of parallel arrows. For a uniform electric field (E = constant), we have

$$\frac{dV}{dr} = \text{constant} \qquad \text{or} \qquad dV \propto dr$$

Therefore, in a uniform electric field, equipotential surfaces differing by same amount of potential difference will be equidistant from each other. Since electric field is perpendicular to the equipotential surface, such surfaces will be a set of parallel planes. Fig. 3.10 shows equipotential surfaces I, II and III at potentials V_1, V_2 and V_3 respectively. Since electric field is in the direction of decrease of potential, $V_1 > V_2 > V_3$. Further, as the equipotential surfaces are equidistant from each other, $V_1 - V_2$ is equal to $V_2 - V_3$.

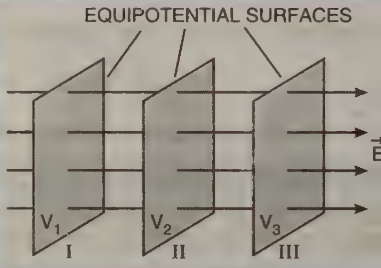

Fig. 3.10

2. For an isolated point charge. The electric field due to an isolated point charge is radial in nature and varies inversely as the square of the distance from the charge. The potential at all the points equidistant from the charge is same. All such points lie on the surface of a spherical shell, such that the charge lies at its centre. Therefore, for a point charge, equipotential surfaces will be a series of concentric spherical shells with the charge at the centre. Since for same change dV in potential,

$$dr \propto \frac{1}{E},$$

the separation dr between the equipotential surfaces will go on increasing with decrease of electric field. Fig. 3.11 shows equipotential surfaces I, II and III due to an isolated positive charge. The potential of each of the three surfaces is different, but it has the same value for all points on the surface. As the separation between surfaces II and III is more than that between I and II, it follows that electric field is stronger at points near the charge and weaker at points away from it. The electric lines of force are perpendicular to equipotential surfaces and point radially outwards.

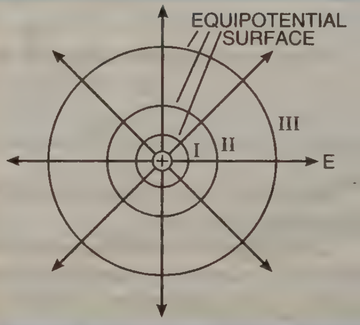

Fig. 3.11

3. For a system of two point charges. Fig. 3.12 and Fig. 3.13 represent the equipotential surfaces and electric lines of force for two equal positive charges and a pair of equal and opposite charges respectively. The dotted lines represent electric lines of force. The thick circles around the charges represent equipotential surfaces due to individual charges. In the two cases, the equipotential surfaces due to the wo charges are obtained by adding potentials at a point due to two charges lgebraically. They have been represented by thick curves or lines.

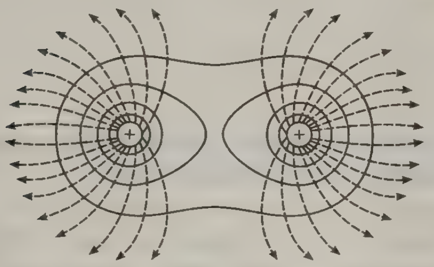

Fig. 3.12

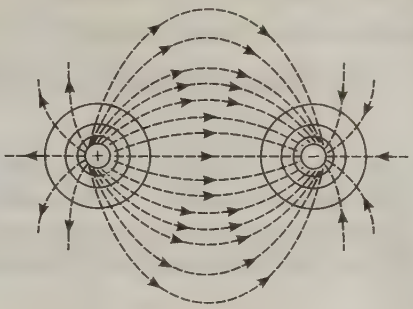

Fig. 3.13.

3.12. ELECTROSTATIC POTENTIAL ENERGY OF A SYSTEM OF CHARGES

The electrostatic potential energy of a system of point charges is defined as the work quired to be done to bring the charges constituting the system to their respective locations om infinity.

We first obtain expression for electrostatic potential energy of a system of two oint charges, then for a system of three point charges and finally we shall generalise e result for a system of n point charges.

(*a*) Potential energy of a system of two point charges. Consider two point harges q_1 and q_2 lying at points A and B, whose locations are $\vec{r_1}$ and $\vec{r_2}$ respectively ig. 3.14].

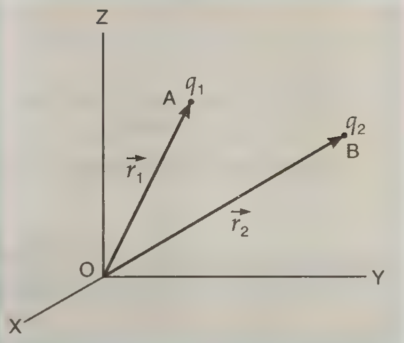

Fig. 3.14

To calculate the electric potential energy of the two charges, remove the two harges to positions, such that they are at infinite distance from each other. First of l, bring the charge q_1 from infinity to its original position A. For this, no work is equired. It is because, when charge q_1 is moved, no electrostatic force due to any ther charge opposes it.

Now, move charge q_2 to its original position B. When charge q_2 is moved, the ectric field due to the charge q_1 lying at point A, opposes it. Hence, work has to e done. The work done in moving charge q_2 from infinity to point B in the electric eld of charge q_1 is given by

$$W = (\text{electric potential due to charge } q_1 \text{ at B}) \times q_2 = \left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{AB}\right)q_2$$

Since $AB = |\vec{r_1} - \vec{r_2}|$, we have

$$W = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{|\vec{r_1} - \vec{r_2}|}$$

The work donw in bringing the two charges to their respective positions is ored as the potential energy of the configuration of two charges *i.e.*

$$U = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{|\vec{r_1} - \vec{r_2}|} \qquad ...(3.34)$$

If distance $|\vec{r_1} - \vec{r_2}|$ is denoted as r_{12}, then

$$U = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{r_{12}} \qquad ...(3.35)$$

The equations (3.34) and (3.35) give electric potential energy of a system of two oint charges.

Key point

Potential energy of a configuration of two charges is due to work done in bringing the charges to their respective positions after having been put infinite distance apart.

(*b*) Potential energy of a system of three point charges. Consider that three oint charges q_1, q_2 and q_3 are lying at locations $\vec{r_1}$, $\vec{r_2}$ and $\vec{r_3}$ respectively. Let us nd the electric potential energy of the system of the three charges.

(*i*) First of all, remove all the three charges to infinite distance from each other nd then move the charge q_1 to its location $\vec{r_1}$. For this, no work has to be done.

(*ii*) Now, move the charge q_2 from infinity to its location $\vec{r_2}$. The work has to be done for moving charge q_2 in the electric field produced by charge q_1 (or due to electric potential of charge q_1) at the location $\vec{r_2}$. The work done for moving the charge q_2 from infinity to location $\vec{r_2}$, when charge q_1 is present at $\vec{r_1}$ is given by

$$W_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{|\vec{r_1} - \vec{r_2}|}$$

(*iii*) Now, move charge q_3 from infinity to its location $\vec{r_3}$. The work, say W_{13} has to be done for moving charge q_3 in the electric field of charge q_1 and work, say W_{23} has to be done for moving it in the electric field of charge q_2. The values of W_{13} and W_{23} are given by

$$W_{13} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_3}{|\vec{r_1} - \vec{r_3}|} \quad \text{and} \quad W_{23} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_2 q_3}{|\vec{r_2} - \vec{r_3}|}$$

Therefore, total work done in order to bring all the three charges at their respective locations and hence the electric potential energy of the system of the three point charges is given by

$$U = W_{12} + W_{13} + W_{23}$$

or
$$U = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{|\vec{r_1} - \vec{r_2}|} + \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_3}{|\vec{r_1} - \vec{r_3}|} + \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_2 q_3}{|\vec{r_2} - \vec{r_3}|}$$

or
$$U = \frac{1}{4\pi\varepsilon_0} \left(\frac{q_1 q_2}{|\vec{r_1} - \vec{r_2}|} + \frac{q_1 q_3}{|\vec{r_1} - \vec{r_3}|} + \frac{q_2 q_3}{|\vec{r_2} - \vec{r_3}|} \right) \qquad \text{...(3.36)}$$

The result (3.36) can also be expressed as

$$U = \frac{1}{2} \left(\frac{1}{4\pi\varepsilon_0} \sum_{j=1}^{3} \sum_{\substack{i=1 \\ j \neq i}}^{3} \frac{q_i q_j}{|\vec{r_i} - \vec{r_j}|} \right) \qquad \text{...(3.37)}$$

The factor $\frac{1}{2}$ has been included for the reason that when potential energy of the three charges is expressed in summation form, each term gets counted twice. For example, if in equation (3.37), a term is obtained for $i = 1$ and $j = 2$, then the same term comes in again for $i = 2$ and $j = 1$.

If we denote the distance $|\vec{r_1} - \vec{r_2}|$, $|\vec{r_1} - \vec{r_3}|$ and $|\vec{r_2} - \vec{r_3}|$ as r_{12}, r_{13} and r_{23} respectively, then

$$U = \frac{1}{4\pi\varepsilon_0} \left(\frac{q_1 q_2}{r_{12}} + \frac{q_1 q_3}{r_{13}} + \frac{q_2 q_3}{r_{23}} \right) \qquad \text{...(3.38)}$$

The result (3.38) can also be expressed as

$$U = \frac{1}{2} \left[\frac{1}{4\pi\varepsilon_0} \sum_{j=1}^{3} \sum_{\substack{i=1 \\ j \neq i}}^{3} \frac{q_i q_j}{r_{ij}} \right] \qquad \text{...(3.39)}$$

(*c*) **Potential energy of a system of *n* point charges.** The expression obtained for the potential energy of a system of three point charges can be easily generalised to a system of *n* point charges. The potential energy of a system of *n* point charges $q_1, q_2, q_3, \ldots, q_n$ present at locations $\vec{r_1}, \vec{r_2}, \vec{r_3}, \ldots, \vec{r_n}$ respectively is given by

$$U = \frac{1}{2} \left(\frac{1}{4\pi\varepsilon_0} \sum_{j=1}^{n} \sum_{\substack{i=1 \\ j \neq i}}^{n} \frac{q_i q_j}{|\vec{r_i} - \vec{r_j}|} \right) \qquad \text{...(3.40)}$$

If we write the distance $|\vec{r_i} - \vec{r_j}|$ as r_{ij}, the above equation may be expressed as

$$U = \frac{1}{2}\left(\frac{1}{4\pi\varepsilon_0}\sum_{j=1}^{n}\sum_{\substack{i=1\\ j\neq i}}^{n}\frac{q_i\, q_j}{r_{ij}}\right) \qquad ...(3.41)$$

3.13. POTENTIAL ENERGY OF AN ELECTRIC DIPOLE, WHEN PLACED IN UNIFORM ELECTRIC FIELD

Suppose that an electric dipole having dipole moment p is placed along a rection making an angle θ with the direction of an external uniform electric field Then, torque acting on the dipole is given by

$$\tau = p\, E \sin\theta$$

If the dipole is rotated through an infinitesimally small angle $d\theta$ against the rque acting on it, then small work done

$$dW = \tau\, d\theta = p\, E \sin\theta\, d\theta$$

Therefore, work done in rotating the dipole from its orientation making an angle with the direction of electric field to θ_2 is given by

$$W = \int_{\theta_1}^{\theta_2} p\, E \sin\theta\, d\theta = p\, E \left| -\cos\theta \right|_{\theta_1}^{\theta_2}$$

or $$W = p\, E\, (\cos\theta_1 - \cos\theta_2)$$

This work done is stored in the dipole in the form of its potential energy.

Therefore, when an electric dipole is rotated inside the electric field, potential ergy stored in the electric dipole and it is given by

$$U = p\, E\, (\cos\theta_1 - \cos\theta_2) \qquad ...(3.42)$$

Let us assume that dipole is initially oriented perpendicular to the electric field d is then brought to the orientation making an angle θ with the field direction. en, potential energy of the dipole, when it makes angle θ with the direction of e electric field can be obtained from equation (3.42) by setting $\theta_1 = 90°$ and $\theta_2 =$ Therefore,

$$U = p\, E\, (\cos 90° - \cos\theta)$$

or $$U = -p\, E \cos\theta \qquad ...(3.43)$$

In vector notation,

$$U = -\vec{p} \cdot \vec{E} \qquad ...(3.44)$$

Key point

The work done in rotating an electric dipole against the torque acting on it due to the electric field is stored in the dipole in the form of its potential energy.

Key point

In a uniform electric field, an electric dipole experiences a torque only. Whereas in a non-uniform field, it experiences torque as well as a net force.

Key point

The potential energy of an electric dipole in an electric field is zero, when electric dipole moment vector is parallel to the field $(\vec{p} \parallel \vec{E})$ and maximum, when antiparallel.

SOLVED NUMERICAL PROBLEMS

pe A. On Potential difference and work done in moving a charge

Problem 3.01. If 100 joule of work must be done to move ectric charge equal to 4 C from a place, where potential –10 volt to another place, where potential is V volt, find e value of V. *(H.P.S.S.C.E. 1998, 1990)*

Sol. Here, $q_0 = 4\,C$; $V_A = -10$ volt; $V_B = V =$ volt;

$$W_{AB} = 100 \text{ joule}$$

Now, $$V_B - V_A = \frac{W_{AB}}{q_0}$$

or $$V - (-10) = \frac{100}{4} = 25 \quad \text{or} \quad V = \mathbf{15\ volt}$$

pe B. On Potential due to a point charge

Problem 3.02. Calculate the electric potential at the rface of a gold nucleus. Given, the radius of nucleus 6·6 × 10–15 m and atomic number of gold = 79. *(H.P.S.S.C.E. 1996)*

Sol. Here, charge on gold nucleus,

$$q = Z\,e = 79 \times 1{\cdot}6 \times 10^{-19}\, C;$$

radius of gold nucleus, $r = 6{\cdot}6 \times 10^{-15}$ m

Therefore, electric potential at the surface of the nucleus,

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r} = \frac{9\times10^9\times79\times1{\cdot}6\times10^{-19}}{6{\cdot}6\times10^{-15}}$$

$$= \mathbf{1{\cdot}724 \times 10^7\ V}$$

Problem 3.03. (*a*) Calculate the potential at a point P due to a charge of 4 × 10–7 C located 9 cm away [Fig. 3.15].

(*b*) Hence, obtain the work done in bringing a charge of 2 × 10–9 C from infinity to the point P. Does the answer depend on the path along which the charge is brought ? *(Text Problem)*

Sol. Here, $q = 4 \times 10^{-7}$ C; $r = 9$ cm $= 0{\cdot}09$ m

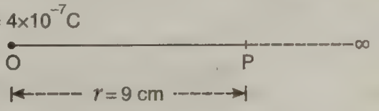

Fig. 3.15

(*a*) Potential at point P due to charge *q*,

$$V_P = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r}$$

$$= 9\times10^9 \times \frac{4\times10^{-7}}{0\cdot09} = \mathbf{4\times10^4\ V}$$

(*b*) From the definition, the potential at point P equals the work done in bringing a unit positive charge from infinity to point P. Therefore, the work done in bringing a charge of 2×10^{-9} C from infinity to point P,

$$W = 2\times10^{-9}\times \text{potential at point P}$$

$$= 2\times10^{-9}\times4\times10^{4}$$

$$= \mathbf{8\times10^{-5}\ J}$$

The work done in bringing the charge from infinity to point P **does not depend** on the path along which the charge is brought.

Problem 3.04. A charge of 20 μC produces an electric field. Two points are 10 cm and 5 cm from this charge. Find the values of potentials at these points and also find the amount of work done to take an electron from one point to the other.

Sol. Here, $q = 20\,\mu C = 20\times10^{-6}$ C

Let A and B be two points at distances 10 cm and 5 cm from the charge. Thus,

$$r_1 = 10\text{ cm} = 0\cdot1\text{ m}\ ;\ r_2 = 5\text{ cm} = 0\cdot05\text{ m}$$

Now, $$V_A = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r_1} = 9\times10^9\times\frac{20\times10^{-6}}{0\cdot1}$$

$$= \mathbf{1\cdot8\times10^6\ V}$$

Also, $$V_B = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r_2} = 9\times10^9\times\frac{20\times10^{-6}}{0\cdot05}$$

$$= \mathbf{3\cdot6\times10^6\ V}$$

$$\therefore\ V_B - V_A = 3\cdot6\times10^6 - 1\cdot8\times10^6 = 1\cdot8\times10^6\text{ V}$$

Work done to take an electron from A to B,

$$W_{AB} = (V_B - V_A)\times\text{charge on electron}$$

$$= 1\cdot8\times10^6\times1\cdot6\times10^{-19} = \mathbf{2\cdot88\times10^{-13}\ J}$$

Problem 3.05. At a point due to a point charge, the values of electric field intensity and potential are 32 N C^{-1} and 16 J C^{-1} respectively. Calculate magnitude of charge and distance of the charge from the point of observation. *(C.B.S.E. 2002)*

Sol. Let the observation point be at a distance *r* from the given point charge *q*. Since at the observation point, the electric field is 32 N C^{-1},

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2} = 32 \qquad ...(i)$$

Also, as the electric potential at the observation point is 16 J C^{-1},

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r} = 16 \qquad ...(ii)$$

Dividing equation (*ii*) by (*i*), we have

$$r = \frac{16}{32} = \mathbf{0\cdot5\ m}$$

Substituting for *r* in equation (*ii*), we have

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{0\cdot5} = 16 \quad\text{or}\quad 9\times10^9\times\frac{q}{0\cdot5} = 16$$

or $$q = \frac{16\times0\cdot5}{9\times10^9} = \mathbf{8\cdot89\times10^{-10}\ C}$$

Type C. On potential due to a group of Charges

Problem 3.06. Calculate the potential at the centre a square ABCD of each side $\sqrt{2}$ m due to charges 2, –2, and 6 μC at four corners of it. *(H.S.S.C.E. 199*

Sol. Four charges q_1, q_2, q_3 and q_4 are placed at the fo corners of the square ABCD as shown in Fig. 3.16.

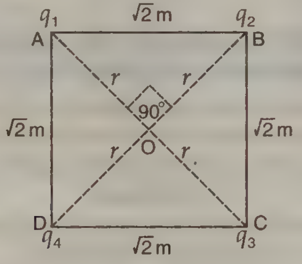

Fig. 3.16

Here, $$q_1 = 2\,\mu C = 2\times10^{-6}\,C\,;$$
$$q_2 = -2\,\mu C = -2\times10^{-6}\,C\,;$$
$$q_3 = -3\,\mu C = -3\times10^{-6}\,C\,;$$
$$q_4 = 6\,\mu C = 6\times10^{-6}\,C$$

and $$AB = BC = CD = AD = \sqrt{2}\text{ m}$$

Let *r* be the distance of each charge from the centre O the square.

Then, $$\sqrt{r^2+r^2} = \sqrt{2} \quad\text{or}\quad r = 1\text{ m}$$

Potential at point O due to charges at the four corne

$$V = \frac{1}{4\pi\varepsilon_0}\left(\frac{q_1}{r}+\frac{q_2}{r}+\frac{q_3}{r}+\frac{q_4}{r}\right)$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{1}{r}(q_1+q_2+q_3+q_4)$$

$$= \frac{9\times10^9}{1}\left(2\times10^{-6}+(-2\times10^{-6})+(-3\times10^{-6})+6\times10^{-}\right.$$

$$= \mathbf{2\cdot7\times10^4\ V}$$

Q. 3.07. A regular hexagon of side 10 cm has a char 5 μC at each of its vertices. Calculate the potential at t centre of the hexagon. *(Text Proble*

Ans. Let O be the centre of the hexagon [Fig. 3.17]. follows that the point O, when joined to the two ends of a si of the hexagon forms an equilateral triangle. Therefore,

$$AO = BO = CO = DO = EO = FO = 10\text{ cm} = 0\cdot1\text{ m}$$

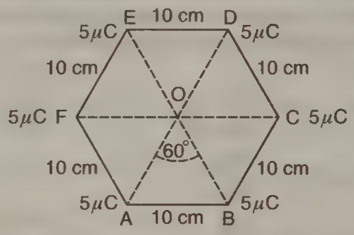

Fig. 3.17

Since at the each corner of the hexagon, a charge of 5 μ *i.e.* 5×10^{-6} C is placed, total electric potential at point O d to the charges at the six corners,

$$V = 6\times\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r}\right)$$

$$= 6\times9\times10^9\times\frac{5\times10^{-6}}{0\cdot1} = \mathbf{2\cdot7\times10^6\ V}$$

Problem 3.08. A cube of side b has a charge q at each of its eight vertices. Determine the potential and electric field due to this charge array at the centre of the cube. *(Text Problem)*

Sol. The charge on each vertex of the cube = q ;
side of the cube = b

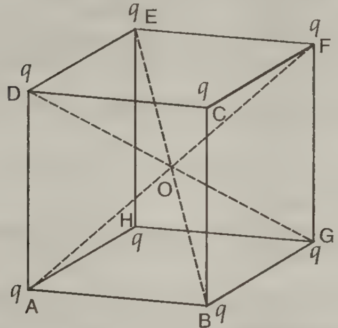

Fig. 3.18

Now, distance r of the centre O of the cube from any vertex of the cube is equal to half of its diagonal of the cube *i.e.*

$$r = \frac{1}{2}\sqrt{b^2 + b^2 + b^2} = \sqrt{3}\,b/2$$

The potential at point O due to charge q at any vertex,

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r}$$

Therefore, potential at the centre of the cube due to charges at its eight vertices,

$$V' = 8\,V = 8 \times \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{\sqrt{3}\,b/2}$$

or $\quad V' = \dfrac{4\,q}{\sqrt{3}\,\pi\,\varepsilon_0\,b}$

From the symmetry, it follows that electric field at point O due to charges at the eight vertices of the cube will be **zero.**

Problem 3.09. A metal wire is bent into a circle of radius 10 cm. It is given a charge of 200 μC, which spreads on it uniformly. Calculate the electric potential at its centre. *(C.B.S.E. 1995)*

Sol. Here r = 10 cm = 0·1 m

and $\quad q = 200\ \mu C = 200 \times 10^{-6}$ C

Consider an elementary portion of the circular wire. Suppose that it possesses a small amount of charge dq over it. If we assume that the charge on elementary portion behave as point charge, then potential due to elementary portion at the centre,

$$dV = \frac{1}{4\pi\varepsilon_0}\cdot\frac{dq}{r}$$

The potential due to the whole circular wire,

$$V = \Sigma\, dV = \Sigma\,\frac{1}{4\pi\varepsilon_0}\,\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0\, r}\,\Sigma\, dq = \frac{1}{4\pi\varepsilon_0}\,\frac{q}{r}$$

$$= 9 \times 10^9 \times \frac{200 \times 10^{-6}}{0{\cdot}1} = \mathbf{1{\cdot}8 \times 10^7\ V}$$

Problem 3.10. Two charges 3×10^{-8} C and -2×10^{-8} C are located 15 cm apart. At what point on the line joining the two charges is the electrical potential zero ? Take the potential at infinity to be zero. *(C.B.S.E. 2000 ; Text Problem)*

Sol. Here, $q_A = 3 \times 10^{-8}$ C ; $q_B = -2 \times 10^{-8}$ C ;
r = 15 cm = = 0·15 m

Let O be the point, where the electric potential is zero due to the two charges [Fig. 3.19].

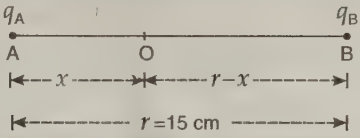

Fig. 3.19

Suppose that the distance AO = x. Then,

$$BO = r - x = 0{\cdot}15 - x$$

Electric potential at point O due to q_A,

$$V_A = \frac{1}{4\pi\varepsilon_0}\,\frac{q_A}{AO}$$

$$= 9 \times 10^9 \times \frac{3 \times 10^{-8}}{x} = \frac{270}{x}$$

Electric potential at point O due to q_B,

$$V_B = \frac{1}{4\pi\varepsilon_0}\,\frac{q_B}{BO}$$

$$= 9 \times 10^9 \times \frac{(-2 \times 10^{-8})}{0{\cdot}15 - x} = -\frac{180}{0{\cdot}15 - x}$$

Since the electric potential at point O is zero, we have

$$V_A + V_B = 0$$

or $\quad \dfrac{270}{x} + \left(-\dfrac{180}{0{\cdot}15 - x}\right) = 0 \quad$ or $\quad \dfrac{270}{x} = \dfrac{180}{0{\cdot}15 - x}$

or $\quad x = 0{\cdot}09$ m = **9 cm (from charge of 3×10^{-8} C)**

Problem 3.11. ABCD is a square of side 0·2 m. Charges of 2×10^{-9}, 4×10^{-9}, 8×10^{-9} coulomb are placed at the corners A, B and C respectively. Calculate the work required to transfer a charge of 2×10^{-9} coulomb from corner D to the centre of the square. *(Karnataka, 1988)*

Sol. The charges of $q_A = 2 \times 10^{-9}$ C ; $q_B = 4 \times 10^{-9}$ C and $q_C = 8 \times 10^{-9}$ C are placed at the corners A, B and C of the square ABCD of each side of length 0·2 m [Fig. 3.20].

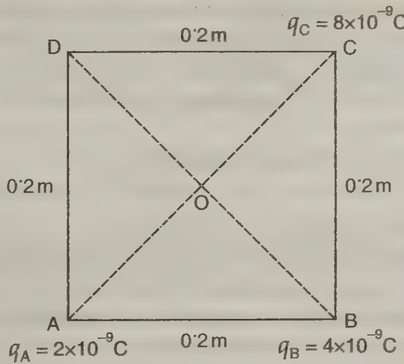

Fig. 3.20

Let V_D be potential at point D due to charges placed at points A, B and C. Then,

V_D = sum of the potentials due the charges q_A, q_B and q_C

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A}{AD} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_B}{BD} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_C}{CD}$$

$$= \frac{1}{4\pi\varepsilon_0}\left(\frac{q_A}{AD} + \frac{q_B}{BD} + \frac{q_C}{CD}\right)$$

Here, AD = CD = 0 · 2 m

and $\quad BD = \sqrt{(0{\cdot}2)^2 + (0{\cdot}2)^2} = 0{\cdot}2\sqrt{2}$ m

$$\therefore \quad V_D = 9\times10^{9}\left(\frac{2\times10^{-9}}{0\cdot2}+\frac{4\times10^{-9}}{0\cdot2\sqrt{2}}+\frac{8\times10^{-9}}{0\cdot2}\right)$$

$$= \frac{9\times10^{9}\times2\times10^{-9}}{0\cdot2}(1+\sqrt{2}+4)$$

$$= 577{\cdot}26 \text{ V}$$

Now, potential at point O due to charges q_A, q_B and q_C,

$$V_O = \frac{1}{4\pi\varepsilon_0}\left(\frac{q_A}{AO}+\frac{q_B}{BO}+\frac{q_C}{CO}\right)$$

Now, $AO = BO = CO = \frac{1}{2}\times$ diagonal of square

$$= \frac{1}{2}\times0\cdot2\sqrt{2} = 0\cdot1\sqrt{2}\text{ m} \quad (\because\ BD = 0{\cdot}2\sqrt{2}\text{ m})$$

$$\therefore \quad V_O = 9\times10^{-9}\times\left(\frac{2\times10^{-9}}{0\cdot1\sqrt{2}}+\frac{4\times10^{-9}}{0\cdot1\sqrt{2}}+\frac{8\times10^{-9}}{0\cdot1\sqrt{2}}\right)$$

$$= \frac{9\times10^{9}\times2\times10^{-9}}{0\cdot1\sqrt{2}}(1+2+4) = 890{\cdot}82\text{ V}$$

Potential difference between the points O and D,

$$V_O - V_D = 890{\cdot}82 - 577{\cdot}26 = 313{\cdot}56\text{ V}$$

Therefore, work done to transfer a charge $q = 2\times10^{-9}$ C from point D to O is given by

$$W = q\times(V_O - V_D) = 2\times10^{-9}\times313{\cdot}56$$

$$= \mathbf{6{\cdot}27\times10^{-7}\ J}$$

Type D. On Potential gradient and electric field

Problem 3.12. Two parallel plates are 5 cm apart and a potential difference of 60 V is set up across them. Find the electric field intensily between the two plates.

Sol. Here, $dV = 60$ V ; $dr = 5$ cm $= 0\cdot05$ m

Now, $$E = -\frac{dV}{dr} = -\frac{60}{0\cdot05} = \mathbf{-1200\ V\ m^{-1}}$$

The negative sign indicates that electric field is directed in the direction of decrease of potential.

Problem 3.13. Calculate the voltage needed to balance an oil drop carrying 10 electrons, when located between plates of a capacitor, which are 5 mm apart. Given, mass of the drop = 3×10^{-16} kg, charge on electron = $1{\cdot}6\times10^{-19}$ C and $g = 9.8$ m s^{-2}. *(C.B.S.E. 1995 S)*

Sol. Here, charge on oil drop,

$$q = 10\,e = 10\times1{\cdot}6\times10^{-19} = 1{\cdot}6\times10^{-18}\text{ C}$$

Mass of oil drop, $m = 3\times10^{-16}$ kg

Distance between the plates of the capacitor,

$$r = 5\text{ mm} = 5\times10^{-3}\text{ m}$$

The electric field at a point is numerically equal to the gradient of electric potential at that point. Since electric field between the plates of a capacitor is uniform, it is given by

$$E = \frac{V}{r}$$

Here, V is potential difference between the plates of the capacitor held at distance r apart.

So that the oil drop is balanced,

$$qE = mg \quad\text{or}\quad q\left(\frac{V}{r}\right) = mg$$

or $$V = \frac{mgr}{q} = \frac{3\times10^{-16}\times9\cdot8\times5\times10^{-3}}{1\cdot6\times10^{-18}} = \mathbf{9{\cdot}19\ V}$$

Type E. On Potential energy of a group of charges

Problem 3.14. (*a*) Determine the electrostatic energy o a system containing two charges 7 μC and – 2 μC separated by a distance of 18 cm.

(*b*) How much work is required to separate the tw charges infinitely away from each other ?

Sol. Here, $q_1 = 7\,\mu C = 7\times10^{-6}$ C ;

$$q_2 = -2\,\mu C = -2\times10^{-6}\text{ C};$$

$$r_{12} = 18\text{ cm} = 0{\cdot}18\text{ m}$$

(*a*) Electrostatic potential energy of the system of tw charges,

$$U = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{r_{12}}$$

$$= 9\times10^{9}\times\frac{(7\times10^{-6})\times(-2\times10^{-6})}{0\cdot18} = \mathbf{-0{\cdot}7\ J}$$

(*b*) When the two charges are separated infinitely awa ($r_{12} = \infty$) from each other, the electrostatic potential energ of the system becomes zero. Therefore,

work required to separate the two charges infinitel away from each other,

$$W = \text{final P.E.} - \text{initial P.E.} = 0 - (-0{\cdot}7) = \mathbf{0{\cdot}7\ J}$$

Problem 3.15. An electron is circulating around th nucleus of a hydrogen atom in a circular orbit of radiu $5{\cdot}3\times10^{-11}$ m. Calculate (*a*) the electric potential at thi radius. (*b*) the electric potential energy of the atom in eV What would be the electric potential due to a heliun nucleus at the same radius. Given, $(4\pi\varepsilon_0)^{-1} = 9\times10^{9}$ m F^{-1} and $e = 1{\cdot}6\times10^{-19}$ C. *(I.S.C.E. 1997*

Ans. Here, $\frac{1}{4\pi\varepsilon_0} = 9\times10^{9}$ m F^{-1} ; $e = 1{\cdot}6\times10^{-19}$ C

(*a*) Radius of electron orbit in hydrogen atom,

$$r = 5{\cdot}3\times10^{-11}\text{ m}$$

The nucleus of hydrogen atom contains one proton Therefore, charge on the nucleus of hydrogen atom,

$$q_1 = +e = 1{\cdot}6\times10^{-19}\text{ C}$$

Electric potential at electron orbit of hydrogen atom,

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{r} = \frac{9\times10^{9}\times1\cdot6\times10^{-19}}{5\cdot3\times10^{-11}} = \mathbf{27{\cdot}17\ V}$$

(*b*) Charge on electron, $q_2 = -e = -1{\cdot}6\times10^{-19}$ C

Therefore, potential energy of H-atom (proton-electror system),

$$U = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{r}$$

$$= \frac{9\times10^{9}\times1\cdot6\times10^{-19}\times(-1\cdot6\times10^{-19})}{5\cdot3\times10^{-11}}$$

$$= -27\cdot17\times1\cdot6\times10^{-19}\text{ J}$$

Now, 1 eV $= 1{\cdot}6\times10^{-19}$ J

$$\therefore \quad U = -\frac{27\cdot17\times1\cdot6\times10^{-19}}{1\cdot6\times10^{-19}} = \mathbf{-27{\cdot}17\ eV}$$

A helium nucleus contains two protons. Therefore, charge on helium nucleus,

$$q = +2e = 2\times1{\cdot}6\times10^{-19} = 3{\cdot}2\times10^{-19}\text{ C}$$

Hence, electric potential at distance r (= $5{\cdot}3\times10^{-11}$ m)

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r} = \frac{9\times10^{9}\times3\cdot2\times10^{-19}}{5\cdot3\times10^{-11}} = \mathbf{54{\cdot}34\ V}$$

Problem 3.16. If one of the two electrons of a H_2 olecule is removed, we get a hydrogen molecular ion H_2^+). In the ground state of a H_2^+, the two protons are eparated by roughly 1·5 Å and the electron is roughly 1 Å rom each proton. Determine the potential energy of the ystem in eV. (1 eV = $1\cdot6 \times 10^{-19}$ J).

Sol. Let r_{12} be the distance between the two protons $_1$and p_2. Further, let r_{13} and r_{23} be the distances of the electron from the protons p_1 and p_2 respectively [Fig. 3.21].

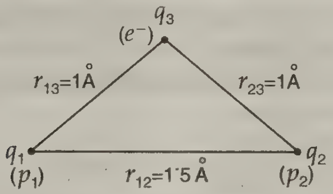

Fig. 3.21

Here, $r_{12} = 1\cdot5$ Å $= 1\cdot5 \times 10^{-10}$ m ;

$r_{13} = r_{23} = 1$ Å $= 10^{-10}$ m,

$q_1 = q_2 = +\,1\cdot6 \times 10^{-19}$ C and $q_3 = -\,1\cdot6 \times 10^{-19}$ C

Therefore, potential energy of the system,

$$U = \frac{1}{4\pi\varepsilon_0}\left(\frac{q_1 q_2}{r_{12}} + \frac{q_1 q_3}{r_{13}} + \frac{q_2 q_3}{r_{23}}\right)$$

$$= 9 \times 10^{-19}\left(\frac{1\cdot6 \times 10^{-19} \times 1\cdot6 \times 10^{-19}}{1\cdot5 \times 10^{-10}} + \frac{1\cdot6 \times 10^{-19} \times (-\,1\cdot6 \times 10^{-19})}{10^{-10}} + \frac{1\cdot6 \times 10^{-19} \times (-\,1\cdot6 \times 10^{-19})}{10^{-10}}\right)$$

$$= 9 \times 10^{9}\,(1\cdot707 \times 10^{-28} - 2\cdot56 \times 10^{-28} - 2\cdot56 \times 10^{-28})$$

$$= 9 \times 10^{9} \times (-\,3\cdot413 \times 10^{-28})$$

$$= -\,30\cdot72 \times 10^{-19}\text{ J}$$

$$= -\frac{30\cdot72 \times 10^{-19}}{1\cdot6 \times 10^{-19}} = \mathbf{-\,19\cdot2\ eV}$$

Type F. On Potential energy of an electric dipole

Problem 3.17. An electric dipole consists of two opposite charges each of 1 μC separated by 2 cm. The dipole is placed in an external uniform field of 10^5 N C^{-1} intensity. Find (*a*) maximum torque exerted by the field on the dipole and (*b*) the work done in rotating the dipole through 180° starting from the position $\theta = 0°$.

Sol. Here, $E = 10^5$ N C^{-1} ; $q = 1\,\mu$C $= 10^{-6}$ C ;

$2a = 2$ cm $= 0\cdot02$ m

$\therefore \quad p = q\,(2a) = 10^{-6} \times 0\cdot02 = 2 \times 10^{-8}$ C m

(*a*) The torque acting on a dipole is given by

$$\tau = p\,E \sin\theta$$

Torque is maximum, when $\sin\theta = 1$

$$\therefore \quad \tau_{max} = 2 \times 10^{-8} \times 10^5 \times 1$$

$$= \mathbf{0\cdot002\ N\ m}$$

(*ii*) Now, work done in rotating the dipole from $\theta = \theta_1$ to $\theta = \theta_2$ is given by

$$W = p\,E\,(\cos\theta_1 - \cos\theta_2)$$

Here, $\theta_1 = 0°,\ \theta_2 = 180°$

$$\therefore \quad W = 2 \times 10^{-8} \times 10^5\,(\cos 0° - \cos 180°)$$

$$= 0\cdot002\,(1 - (-1))$$

$$= \mathbf{0\cdot004\ J}$$

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 3.18. A point charge of 8 mC is located at the origin [Fig. 3.22]. Calculate the work done in taking a nall charge of $-\,2 \times 10^{-9}$ C from a point A (0, 0, 3 cm) to a oint B (0, 4 cm, 0) via a point C (0, 6 cm, 9 cm).

(*Text Problem*)

Ans. Fig. 3.22 shows the charge q (= 8 mC or 8×10^{-3} C) ocated at the origin. A charge q_0 (= -2×10^{-9} C) is moved from oint A (0, 0, 3 cm) to point B (0, 4 cm, 0) via point C (0, 6 cm, 9 cm).

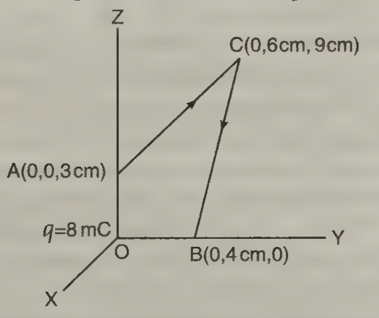

Fig. 3.22

The initial distance of charge q_0 from q,

r_A = OA = 3 cm = 0·03 m

The final distance of charge q_0 from q,

r_B = OB = 4 cm = 0·04 m

Work done in moving the charge q_0 from point A to B is ndependent of the path followed and depends only upon the initial and final distances *i.e.* r_A and r_B. Therefore, work done to move charge q_0 from point A to B is given by

$$W = \frac{1}{4\pi\varepsilon_0}\cdot q\,q_0\left(\frac{1}{r_B} - \frac{1}{r_A}\right)$$

$$= 9 \times 10^9 \times 8 \times 10^{-3} \times (-\,2 \times 10^{-9}) \times \left(\frac{1}{0\cdot04} - \frac{1}{0\cdot03}\right)$$

$$= \mathbf{1\cdot2\,J}$$

Problem 3.19. Two tiny spheres carrying charges 1·5 μC and 2·5 μC are located 30 cm apart. Find the potential and electric field (*a*) at the mid-point of the line joining the two charges and (*b*) at a point 10 cm from this mid-point in a plane normal to the line and passing through the mid-point. (*Text Problem*)

Sol. Here, $q_A = 1\cdot5\,\mu$C $= 1\cdot5 \times 10^{-6}$ C ;

$q_B = 2\cdot5\,\mu$C $= 2\cdot5 \times 10^{-6}$ C

(*a*) The point P is mid-point of the line joining the two charges [Fig. 3.23].

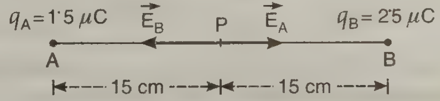

Fig. 3.23

Therefore, AP = BP = 15 cm = 0·15 m

Potential at point P due to the two charges,

$$V = V_A + V_B = \frac{1}{4\pi\varepsilon_0}\left(\frac{q_A}{AP} + \frac{q_B}{BP}\right)$$

$$= 9 \times 10^9 \left(\frac{1{\cdot}5 \times 10^{-6}}{0{\cdot}15} + \frac{2{\cdot}5 \times 10^{-6}}{0{\cdot}15}\right) = \mathbf{2{\cdot}4 \times 10^5\ V}$$

Electric field at point P due to charge q_A,

$$E_A = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A}{(AP)^2} = 9 \times 10^9 \times \frac{1{\cdot}5 \times 10^{-6}}{(0{\cdot}15)^2}$$

$$= 6 \times 10^5\ N\ C^{-1} \qquad \text{(along PB)}$$

Electric field at point P due to charge q_B,

$$E_B = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_B}{(BP)^2} = 9 \times 10^9 \times \frac{2{\cdot}5 \times 10^{-6}}{(0{\cdot}15)^2}$$

$$= 10^6\ N\ C^{-1} \qquad \text{(along PA)}$$

Therefore, net electric field at point P due to the two charges,

$$E = E_B - E_A = 10^6 - 6 \times 10^5$$

$$= \mathbf{4 \times 10^5\ N\ C^{-1}} \qquad \textbf{(along PA)}$$

(*b*) The point Q is at a distance of 10 cm from the mid-point P on a plane normal to the line AB and passing through the point P [Fig. 3.24].

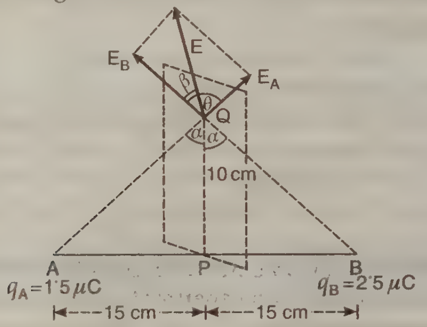

Fig. 3.24

Now, $AQ = BQ = \sqrt{15^2 + 10^2} = 18\ cm = 0 \cdot 18\ m$

Potential at point Q due to the two charges,

$$V = V_A + V_B$$

or $$V = \frac{1}{4\pi\varepsilon_0}\left(\frac{q_A}{AQ} + \frac{q_B}{BQ}\right)$$

$$= 9 \times 10^9 \left(\frac{1{\cdot}5 \times 10^{-6}}{0{\cdot}18} + \frac{2{\cdot}5 \times 10^{-6}}{0{\cdot}18}\right)$$

$$= \mathbf{2 \times 10^5\ V}$$

Electric field at point Q due to charge q_A,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A}{(AQ)^2} = 9 \times 10^9 \times \frac{1{\cdot}5 \times 10^{-6}}{(0{\cdot}18)^2}$$

$$= 4{\cdot}167 \times 10^5\ N\ C^{-1} \qquad \text{(along AQ)}$$

Electric field at point Q due to charge q_B,

$$E_B = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_B}{(BQ)^2} = 9 \times 10^9 \times \frac{2{\cdot}5 \times 10^{-6}}{(0{\cdot}18)^2}$$

$$= 6{\cdot}944 \times 10^5\ N\ C^{-1} \qquad \text{(along BQ)}$$

The net electric field at point Q is given by

$$E = (E_A{}^2 + E_B{}^2 + 2\,E_A\,E_B \cos\theta)^{1/2},$$

where θ is angle between the directions of E_A and E_B.

If $\angle AQP = \angle BQP = \alpha$, then $\theta = 2\,\alpha$

In right angled Δ APQ,

$$\tan\alpha = \frac{15}{10} = 1{\cdot}5 \qquad \text{or} \qquad \alpha = 56{\cdot}3°$$

$$\therefore \quad \theta = 56{\cdot}3° \times 2 = 112{\cdot}6°$$

and $$E = [(4{\cdot}167 \times 10^5)^2 + (6{\cdot}944 \times 10^5)^2 + 2 \times 4{\cdot}167 \times 10^5 \times 6{\cdot}944 \times 10^5 \cos 112{\cdot}6°]^{\frac{1}{2}}$$

$$= 10^5 \times [17{\cdot}364 + 48{\cdot}219 + 57{\cdot}871 \times (-0{\cdot}3843)]^{\frac{1}{2}}$$

$$= \mathbf{6{\cdot}58 \times 10^5\ N\ C^{-1}}$$

Suppose that the direction of E makes an angle β wit the direction of E_B. Then,

$$\tan\beta = \frac{E_A \sin\theta}{E_B + E_A \cos\theta}$$

$$= \frac{4{\cdot}167 \times 10^5 \sin 112{\cdot}6°}{6{\cdot}944 \times 10^5 + 4{\cdot}167 \times 10^5 \cos 112{\cdot}6°}$$

$$= \frac{4{\cdot}167 \times 10^5 \times 0{\cdot}9232}{6{\cdot}944 \times 10^5 + 4{\cdot}167 \times 10^5 \times (-0{\cdot}3843)}$$

$$= \frac{3{\cdot}847}{6{\cdot}944 - 1{\cdot}601} = 0{\cdot}7193$$

or $\beta = \mathbf{35{\cdot}7°}$ **(with the direction of E_B)**

Note. To find the direction of E w.r.t. the line AB, suppos that $\angle QBP = \gamma$. Then,

$$\gamma = 90° - \alpha = 90° - 56{\cdot}3° = 33{\cdot}7°$$

The resultant electric field is inclined at an angle $\gamma +$ *i.e.* $33{\cdot}7° + 35{\cdot}7°$ = **69·4° with the line AB joining the tw charges.**

Problem 3.20. An infinite number of charges eac equal to q are placed along the X-axis at $x = 1$, $x = 2$ $x = 4$, $x = 8$..... and so on.

(*a*) Find potential at the point X = 0 due to this set o charges.

(*b*) What will be the potential, if in the above set up the consecutive charges have opposite sign ? (*I.I.T. 1974*

Sol. Suppose that charges q_1, q_2, q_3, q_4, ... are place at distances r_1, r_2, r_3, r_4, ... from the origin. Then, potentia at the origin ($x = 0$) due to the system of charges,

$$V = \frac{1}{4\pi\varepsilon_0}\left[\frac{q_1}{r_1} + \frac{q_2}{r_2} + \frac{q_3}{r_3} + \frac{q_4}{r_4} + ...\right]$$

(*a*) Here, $q_1 = q_2 = q_3 = ... = q$

and $r_1 = 1,\ r_2 = 2,\ r_3 = 3, r_4 = 4,$ .....

$$\therefore \quad V = \frac{1}{4\pi\varepsilon_0}\left[\frac{q}{1} + \frac{q}{2} + \frac{q}{4} + \frac{q}{8} + ...\right]$$

$$= \frac{1}{4\pi\varepsilon_0} \cdot q\left[\frac{1}{1} + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + ...\right] = \frac{1}{4\pi\varepsilon_0} \cdot q \, . S_\infty$$

where $$S_\infty = \frac{1}{1} + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + ...$$

i.e. sum of a geometrical progression, whose first term $a =$ and the common ratio $r = 1/2$. Therefore,

$$S_\infty = \frac{a}{1-r} = \frac{1}{1 - 1/2} = 2$$

Hence, $$V = \frac{1}{4\pi\varepsilon_0} q \times 2 = \frac{q}{2\pi\varepsilon_0}$$

(*b*) When the consecutive charges have opposite sign,

$$V=\frac{1}{4\pi\varepsilon_0}\left[\frac{q}{1}-\frac{q}{2}+\frac{q}{4}-\frac{q}{8}+.....\right]$$

$$=\frac{1}{4\pi\varepsilon_0}\cdot q\left[\frac{1}{1}-\frac{1}{2}+\frac{1}{4}-\frac{1}{8}+.....\right]$$

$$=\frac{1}{4\pi\varepsilon_0}\cdot q\times\frac{1}{1-(-1/2)}=\frac{q}{6\pi\varepsilon_0}$$

Problem 3.21. Fig. 3.25 shows a charge array known as an electric quadrupole. For a point P on the axis of the uadrupole, obtain the dependence of potential on distance for $r/a>>1$. (*Text Problem*)

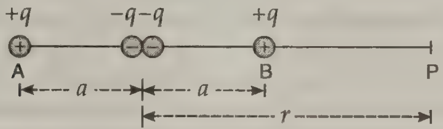

Fig. 3.25

Sol. The electric potential V at the point P due to electric uadrupole can be found by just adding the potentials at point due to the four charges forming the quadrupole. Thus,

$$V=\frac{1}{4\pi\varepsilon_0}\left(\frac{q}{AP}+\frac{(-q)}{BP}+\frac{(-q)}{BP}+\frac{q}{CP}\right)$$

or
$$V=\frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{AP}-\frac{2}{BP}+\frac{1}{CP}\right)$$

Here, $AP=r+a$; $BP=r$ and $CP=r-a$

$$\therefore\quad V=\frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r+a}-\frac{2}{r}+\frac{1}{r-a}\right)$$

$$=\frac{q}{4\pi\varepsilon_0}\times\frac{r(r-a)-2(r^2-a^2)+r(r+a)}{r(r^2-a^2)}$$

$$=\frac{q}{4\pi\varepsilon_0}\cdot\frac{2qa^2}{r(r^2-a^2)}$$

Since $r/a>>1$ or $r>>a$; in the above expressin, a^2 can e neglected in comparison to r^2.

$$\therefore\quad V=\frac{1}{4\pi\varepsilon_0}\cdot\frac{2qa^2}{r(r^2)}=\frac{1}{4\pi\varepsilon_0}\cdot\frac{2qa^2}{r^3}$$

Thus, for $r/a>>1$, potential due to an electric uadrupole falls off as $1/r^3$.

Problem 3.22. Three point charges q, $2q$, $8q$ are to be placed on a 0·09 m long straight line. Find the ositions, where the charges should be placed such that the otential energy of this system is minimum. In this onfiguration, what is the electric field at the charge q due o the other two charges ?

Sol. The potential energy of the system of three charges , $2q$ and $8q$ is contributed by the three pairs, which these harges form with one another. So that the potential energy f the system is minimum, the first condition is that the harges constituting the strongest pair *i.e.* charges $2q$ and $8q$ hould be at the largest separation and the smallest charge hould be between them. Therefore, the charges should be placed as shown in Fig. 3.26.

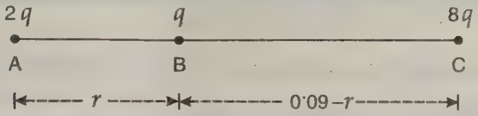

Fig. 3.26

Thus, the distance between the charges $2q$ and $8q$,

$$AC=0{\cdot}09\text{ m}$$

Let $AB=r$. Then, $BC=(0{\cdot}09-r)$

The potential energy of the system

$$U=\frac{1}{4\pi\varepsilon_0}\cdot\left[\frac{(2q)q}{AB}+\frac{q(8q)}{BC}+\frac{(2q)(8q)}{AC}\right]$$

$$=\frac{1}{4\pi\varepsilon_0}\cdot 2q^2\left[\frac{1}{r}+\frac{4}{(0{\cdot}09-r)}+\frac{8}{0{\cdot}09}\right]$$

$$=\frac{1}{4\pi\varepsilon_0}\cdot 2q^2\cdot x,$$

where
$$x=\frac{1}{r}+\frac{4}{(0{\cdot}09-r)}+\frac{8}{0{\cdot}09}$$

The potential energy will be minimum, if x is minimum

i.e.
$$\frac{dx}{dr}=0\quad\text{or}\quad\frac{d}{dr}\left[\frac{1}{r}+\frac{4}{(0{\cdot}09-r)}+\frac{8}{0{\cdot}09}\right]=0$$

$$\text{or}\quad-\frac{1}{r^2}+\frac{4}{(0{\cdot}09-r)^2}+0=0\quad\text{or}\quad\frac{1}{r^2}=\frac{4}{(0{\cdot}09-r)^2}$$

or $r=$ **0·03 m**

The electric field at point B (the position of charge q)

$$E=E_A-E_B=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q(2q)}{(0{\cdot}03)^2}-\frac{1}{4\pi\varepsilon_0}\cdot\frac{q(8q)}{(0{\cdot}06)^2}=0$$

Problem 3.23. In a hydrogen atom, the electron and proton are bound at a distance of about 0·53 Å.

(*a*) Estimate the potential energy of the system in eV, taking the zero of potential energy at infinite separation of the electron from proton.

(*b*) What is the minimum work required to free electron, given that its kinetic energy in the orbit is half the magnitude of potential energy obtained in (*a*) ?

(*c*) What is the answer to (*a*) above, if the zero of potential energy is taken at 1·06 Å separation ? (*Text Problem*)

Ans. Here, charge on electron, $q_1=-1{\cdot}6\times10^{-19}$ C ;

charge on proton $=q_2=1{\cdot}6\times10^{-19}$ C

distance between electron and proton,

$$r_{12}=0{\cdot}53\text{ Å}=0{\cdot}53\times10^{-10}\text{ m}$$

(*a*) Potential energy of system,

$$U=\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1q_2}{r_{12}}$$

$$=9\times10^9\times\frac{(-1{\cdot}6\times10^{-19})\times1{\cdot}6\times10^{-19}}{0{\cdot}53\times10^{-10}}$$

$$=-43{\cdot}47\times10^{-19}\text{ J}$$

$$=-\frac{43{\cdot}47\times10^{-19}}{1{\cdot}6\times10^{-19}}=-27{\cdot}17\text{ eV}$$

At infinite separation, potential energy is zero. Therefore, if zero of potential energy is taken at infinite separation,

potential energy of the system $=-27{\cdot}17-0=$ **−27·17 eV** (*b*) The magnitude of kinetic energy of electron (always positive) is half of the potential energy.

Therefore, K.E. of electron $= \frac{27\cdot17}{2} = 13\cdot585$ eV

Therefore, total energy of electron

$= -27\cdot17 + 13\cdot585 = \mathbf{-13\cdot585\ eV}$

Therefore, work required to free the electron

$= 0 - (-13\cdot585) = \mathbf{13\cdot585\ eV}$

(*c*) Potential energy of system at 1·06 Å (= $1\cdot06 \times 10^{-10}$ m) separation,

$$U' = 9 \times 10^9 \times \frac{(-1\cdot6 \times 10^{-19}) \times 1\cdot6 \times 10^{-19}}{1\cdot06 \times 10^{-10}}$$

$$= -21\cdot74 \times 10^{-19}\ \text{J}$$

$$= -\frac{21\cdot74 \times 10^{-19}}{1\cdot6 \times 10^{-19}}\ \text{eV} = -13\cdot585\ \text{e V}$$

If – 13·585 eV is taken as zero of potential energy, then potential energy of the system

$= -27\cdot17 - (-13\cdot585) = \mathbf{-13\cdot585\ eV}$

Problem 3.24. A molecule of a substance has permanent electric dipole moment equal to 10^{-29} C m. A mole of this substance is polarized (at low temperature) by applying a strong electrostatic field of magnitude 10^6 V m^{-1}. The direction of the field is suddenly changed by an angle of 60°. Estimate the heat released by the substance in aligning its dipoles along the new direction of the field. For simplicity, assume 100% polarization of the sample.

(*Text Problem*)

Sol. Here, strength of electrostatic field, $E = 10^6$ V m^{-1}

Electric dipole moment of a molecule, $p = 10^{-29}$ C m

In one mole, there are molecules equal to Avogadro number N (= $6\cdot023 \times 10^{23}$ mole^{-1}).

Therefore, electric dipole moment of one mole of substance,

$$N\,p = 6\cdot023 \times 10^{23} \times 10^{-29} = 6\cdot023 \times 10^{-6}\ \text{C m}$$

When the substance is completely polarised, the electric dipole moment is along the direction of the electric field *i.e.* $\theta = 0°$.

Therefore, initial potential energy of the molecular dipoles,

$$U_1 = (N\,p)\,E \cos\theta = 6\cdot023 \times 10^{-6} \times 10^6 \times 1 = 6\cdot023\ \text{J}$$

When the direction of the electric field is changed by 60°, then final potential energy of the molecular dipoles,

$$U_2 = (N\,p)\,E \cos 60° = 6\cdot023 \times 10^{-6} \times 10^6 \times 0\cdot5$$
$$= 3\cdot012\ \text{J}$$

The loss in potential energy of the dipoles is released as the heat.

Therefore, heat released,

$U_1 - U_2 = 6\cdot023 - 3\cdot012 = \mathbf{3\cdot011\ J}$

FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 3.01. What is the work done by the field of a nucleus in a complete circular orbit of the electron ? What, if the orbit is elliptical ?

Ans. In either case, work done by the field is zero. It is because,

$$\oint \vec{E}\,.\,\vec{dl} = 0$$

Q. 3.02. A charge 5 μC is placed at a point. What is the work required to carry 1 C of charge once round it in a circle of 12 cm radius ?

Ans. It is zero. It is because, all the points on the circular path are at same potential.

Q. 3.03. What would be the work done, if a point charge +*q* is taken from a point A to a point B on the circumference of a circle drawn with another point charge +*q* at the centre ? (*C.B.S.E. 2001 S*)

Ans. Since points A and B are at the same distance from the charge + *q* placed at centre of the circle [Fig. 3.27], the points A and B are at same potential.

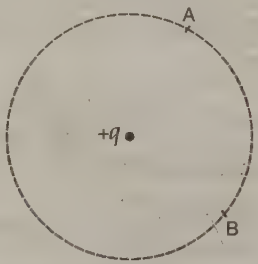

Fig. 3.27

Hence, work done in taking a charge + *q* from point A to B is zero.

Q. 3.04. What is the work done in moving a 2 μC point charge from corner A to corner B of a square ABCD [Fig. 3.28], when a 10 μC charge exists at the centre of the square ? (*C.B.S.E. 1998 S*)

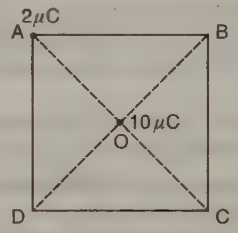

Fig. 3.28

Ans. The points A and B are at the same distance from 10 μC charge. Since $V_A = V_B$, no work will be done in moving a 2 μC charge from point A to B.

Q. 3.05. A uniform field E exists between two charged plates as shown in Fig. 3.29. What would be the work done in moving a charge *q* along the closed rectangular path ABCDA ? (*C.B.S.E. 2001 S*)

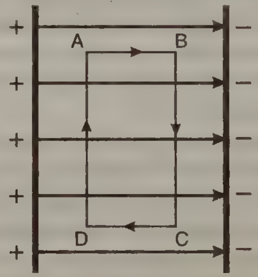

Fig. 3.29

Ans. It is zero.

Also refer to SAQ 3.04.

Q. 3.06. Define electric potential difference between two points. Is it scalar or vector ? *(P.S.S.C.E. 2001 ; H.S.S.C.E. 1996)*

Ans. For definition, refer to section 3.03.

Electric potential difference is a scalar quantity.

Q. 3.07. 5 J work is done in moving a positive charge of 0·5 C between two points. What is the potential difference between these points ? *(I.S.C.E. 1995)*

Ans. Now, $V_B - V_A = \frac{W_{AB}}{q_0} = \frac{5}{0 \cdot 5} = 10$ **volt**

Q. 3.08. A charge of 2 C moves between two plates maintained at a potential difference of 1 volt. What is the energy acquired by the charge ? *(I.S.C.E. 1994)*

Ans. Energy gained by charge = $V.\, q = 1 \times 2 = 2$ **J**

Q. 3.09 If a point charge + q is taken first from A to C and then from C to B of a circle drawn with another point charge + q as centre, then along which path more work will be done ? *(C.B.S.E. 2001 S)*

Ans. As explained in VSAQ 3.03, points A and B are at same potential [Fig. 3.30]. It follows that

$$V_C - V_A = V_C - V_B$$

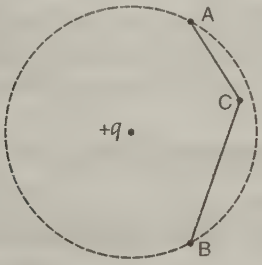

Fig. 3.30

Hence, work done in taking a point charge from A to C or from C to B will be the same.

Q. 3.10. Define electric potential at a point in an electric field. *(P.S.S.C.E. 2001 ; I.S.C.E. 1998)*

Ans. Refer to section 3.04.

Q. 3.11. Is electric potential a scalar or a vector quantity ?

Ans. It is scalar quantity.

Q. 3.12. Define the unit of electric potential. *(P.S.S.C.E. 2002, 2000, 1999, 1998 S)*

Ans. It is volt. For definition, refer to section 3.04.

Q. 3.13. Name the physical quantity, whose SI unit is joule coulomb^{-1}. *(C.B.S.E. 1998)*

Ans. Electric potential or potential difference.

Q. 3.14. How is electric field at a point related to potential gradient ?

Ans. Electric field at any point is equal to the negative of potential gradient at that point *i.e.*

$$E = -\frac{dV}{dr}$$

Q. 3.15. In a certain 0·1 m^3 of space, electric potential is found to be 5 V throughout. What is the electric field in this region ? *(I.S.S.C.E. 1997)*

Ans. Now, $E = -\frac{dV}{dr}$

As electric potential is 5 V throughout *i.e.* constant, electric field in the region will be zero.

Q. 3.16. The electric potential is constant in a region. What can you say about electric field there ? *(H.S.S.C.E. 2001 ; H.P.S.S.C.E. 1998 S)*

Ans. We know, $E = -\frac{dV}{dr}$

Since V is constant, electric field is zero.

Q. 3.17. If the electrostatic field at a given point is zero, must the electrostatic potential be also zero at that point ?

Ans. No. Electric potential may be zero or constant at that point.

Q. 3.18. Two protons A and B are placed between two parallel plates having a potential difference V as shown in the Fig. 3.31. Will these protons experience equal or unequal force ? *(C.B.S.E. 1998)*

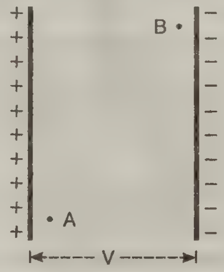

Fig. 3.31

Ans. The electric field due to the potential difference V applied across the two parallel plates of the capacitor is same everywhere. Hence, two protons A and B will experience equal force.

Q. 3.19. We know that electric field is discontinuous across the surface of a charged conductor. Is electric potential also discontinuous there ? *(Text Question)*

Ans. No, electric potential is continuous.

Q. 3.20. What is an equipotential surface ? *(P.S.S.C.E. 2002, 2000, 1999, 1998 S, 1997 ; H.S.S.C.E. 1997 S)*

Ans. *Any surface, which has same electrostatic potential everywhere, is called an equipotential surface.*

Q. 3.21. What is the shape of equipotential surfaces for a given point charge ? *(P.S.S.C.E. 2001 ; C.B.S.E. 1995)*

Ans. For a point charge, the equipotential surfaces are concentric spherical shells, whose centres are located at the given point charge.

Q. 3.22. What is the shape of equipotential surfaces for a uniform electric field ? *(P.S.S.C.E. 2001)*

Ans. For a uniform electric field, equipotential surfaces are planes at right angle to the direction of electric field.

Q. 3.23. How much work is done in moving a charge 500 μC charge between two points on an equipotential surface ? *(C.B.S.E. 2002, 2000, 1996 ; H.P.S.S.C.E. 2002)*

Or

No work is done in moving a test charge over an equipotential surface. Explain, why. *(P.S.S.C.E. 2001)*

Ans. As the two points on an equipotential surface are at the same potential, no work is done in moving a charge between two points.

Q. 3.24. A charge of +1 C is placed at the centre of a spherical shell of radius 10 cm. What will be the work done in moving a charge of +1 μC on its surface through a distance of 5 cm ? *(H.S.S.C.E. 1998 S)*

Ans. It is zero.

Q. 3.25. What is the direction of electric field w.r.t. an equipotential surface ?

Ans. It is along the normal to the equipotential surface.

Q. 3.26. Why does a configuration of charges possess potential energy ?

Ans. Work done in putting the charges at their present locations gets stored in the configuration as its potential energy.

Q. 3.27. When is the potential energy of an electric dipole maximum, when placed in uniform electric field ?

Ans. The potential energy of an electric dipole is maximum, when it is aligned antiparallel to electric field.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 3.01. Work done in moving a test charge between two points in an electric field is independent of the path followed. Comment.

Ans. The work done in moving a test charge between two points in an electric field is independent of path *i.e.* the work done depends only on the location of initial and final positions of the charge. In fact, it is true for all the fields obeying inverse square law.

Q. 3.02. A positive charge + q is located at a point. What is the work done, if a unit positive charge is carried once around this charge along a circle of radius r about this point ? (*I.I.T. 1974*)

Ans. The potential at each point on the circular path around the charge are at same potential *i.e.* potential difference between the initial and final position is zero.

Therefore, work done, $W = V \times q = 0 \times 1 = 0$

Q. 3.03. If a point charge be rotated in a circle of radius r around a charge q, what will be work done and why ? (*P.S.S.C.E. 1996*)

Ans. Refer to SAQ 3.02.

Q. 3.04. The intensity of an electric field inside a capacitor is $\vec{E}$. Calculate the work needed to move a charge q along a closed rectangular path ABCD [Fig. 3.32].

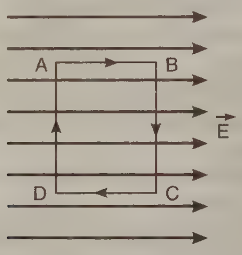

Fig. 3.32

Ans. Force on charge q in electric field $\vec{E}$, $\vec{F} = q\vec{E}$

Work done to move charge q along path ABCD,

$$W = W_{AB} + W_{BC} + W_{CD} + W_{DA}$$

$$= q\vec{E}.\overrightarrow{AB} + q\vec{E}.\overrightarrow{BC} + q\vec{E}.\overrightarrow{CD} + q\vec{E}.\overrightarrow{DA}$$

$$= qE\,(AB)\cos 0^\circ + qE\,(BC)\cos 90^\circ + qE\,(CD)\cos 180^\circ + qE\,(DA)\cos 90^\circ$$

$$= qE\,(AB) + 0 + qE\,(CD)\,(-1) + 0$$

$$= qE\,(AB) - qE\,(CD) = 0$$

Q. 3.05. Fig. 3.33 (*a*) and 3.33 (*b*) show the field lines of a single positive and negative charge respectively :

(*i*) Give the sign of the potential difference $V_P - V_Q$ and $V_B - V_A$.

(*ii*) Give the sign of the potential energy difference of a small negative charge between the points Q and P ; A and B.

(*iii*) Give the sign of the work done by the field in moving a small positive charge from point Q to P.

(*iv*) Give the sign of the work done by an external agency in moving a small negative charge from point B to A.

(*v*) Does the kinetic energy of a small negative charge increase or decrease in going from point B to A ? (*Text Question*)

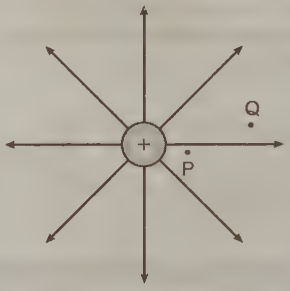

Fig. 3.33 (*a*)

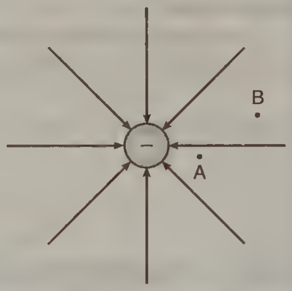

Fig. 3.33 (*b*)

Ans. (*i*) In Fig. 3.33 (*a*), as the field is due to positive charge, $V_P - V_Q > 0$.

In Fig. 3.33 (*b*), as the field is due to negative charge, $V_A - V_B < 0$ or $V_B - V_A > 0$.

(*ii*) The potential energy of a negative charge at point Q will be negative and at point P, it will be still more negative. Therefore,

$$(P.E.)_Q - (P.E.)_P > 0$$

For similar reasons,

$$(P.E.)_A - (P.E.)_B > 0$$

(*iii*) A small positive charge will tend to move from point P to Q and the work done by the field in moving the charge from point P to Q will be positive. Therefore, work done by electric field in moving a small positive charge from point Q to P will be negative.

(*iv*) For the reasons as given in (*iii*), work done by external agency in moving small negative charge from B to A will be positive.

(*v*) As the potential energy of the negative charge increases, kinetic energy of the negative charge decreases in going from point B to A.

Q. 3.06. A point charge q is placed at O as shown in Fig. 3.34. Is $V_A - V_B$ positive, negative or zero, if q is a (*i*) positive, (*ii*) negative charge ? (*C.B.S.E. 2001 S*)

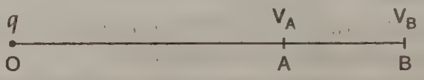

Fig. 3.34

Ans. Let $OA = r_A$ and $OB = r_B$.

Then, $$V_A - V_B = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r_A} - \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r_B}$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r_A} - \frac{1}{r_B}\right)$$

Since $r_A < r_B$, $\frac{1}{r_A} - \frac{1}{r_B}$ = a positive quantity. It follows

(*i*) if q is a positive charge, $V_A - V_B$ = **positive**
(*ii*) if q is a negative charge, $V_A - V_B$ = **negative**

Q. 3.07. The electric potential at 0·1 m from a point ge is 50 V. What is the magnitude of the charge ?

(P.S.S.C.E. 1998 S ; H.S.S.C.E. 1992)

Ans. Here, V = 50 volt ; r = 0·1 m

Now, $$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r}$$

$$\therefore \quad q = 4\pi\varepsilon_0 V r = \frac{1}{9\times10^9}\times 50\times 0{\cdot}1$$

$$= \frac{5}{9}\times10^{-9}\ \text{C}$$

Q. 3.08. Define electric potential at a point. When kept n electric field does a proton move from lower to higher ential or from higher to lower potential region ?

(C.B.S.E. 1997)

Ans. For definition of electric potential, refer to section .

In an electric field, a proton (positive charged particle) move in the direction of electric field *i.e.* from the higher wer potential region.

Q. 3.09. Is the electrostatic potential necessarily zero point, where the electric field strength is zero ? Give xample to illustrate your answer.

Ans. If the electric field strength is zero at a point, the trostatic potential is not necessarily zero at that point. For nple, at a point midway between two equal and similar ges, the electric field strength is zero but the electrostatic ential is twice that due to a single charge.

Q. 3.10. Derive an expression for the potential at a nt along the axial line of a short electric dipole.

(C.B.S.E. 2001 S)

Ans. Fig. 3.35 shows an electric dipole consisting of ges – q at point A and + q at point B. Let P be any point he axial line of the dipole at a distance r from its centre.

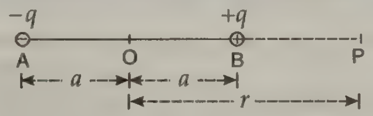

Fig. 3.35

If $2a$ is length of the dipole, then

PA = $r + a$ and PB = $r - a$

Electric potential at point P due to the dipole,

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{(-q)}{PA} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{PB}$$

$$= -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{(r+a)} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{(r-a)}$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q\left(\frac{1}{r-a} - \frac{1}{r+a}\right)$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot q\,\frac{(r+a)-(r-a)}{(r^2-a^2)}$$

or $$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{p}{(r^2-a^2)}$$

For a dipole of short length, a^2 can be neglected as compared to r^2. Then,

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{p}{r^2}$$

Q. 3.11. Show mathematically that the potential at a point on the equitorial line of an electric dipole is zero.

(C.B.S.E. 2001 S)

Ans. Fig 3.36 shows an electric dipole consisting of charges – q at point A and + q at point B.

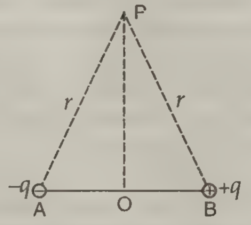

Fig. 3.36

Let P be at point on the equitorial line of the dipole.

Then, PA = PB = r (say)

Electrical potential at point P due to the dipole,

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{(-q)}{PA} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{PB}$$

$$= -\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r} = 0$$

Q. 3.12. What is an equipotential surface ? Give two properties of equipotential surface. *(H.S.S.C.E. 2001)*

Ans. Equipotential surface. Refer to section 3.09

Properties of equipotential surface. Refer to section 3.10.

Q. 3.13. What is an equipotential surface ? Show that the electric field is always directed perpendicular to an equipotential surface. *(C.B.S.E. 2001 S)*

Ans. Equipotential surface. Refer to section 3.09.

Let $\vec{E}$ be electric field at a point on equipotential surface. Then, small work done in moving a test charge q_0 through a small displacement $\vec{dr}$ along the surface,

$$dW = \vec{F}\cdot d\vec{r} = (-q_0\vec{E})\cdot d\vec{r}$$

Since work done in moving a test charge along an equipotential surface is always zero,

$$(-q_0\vec{E})\cdot d\vec{r} = 0 \quad \text{or} \quad \vec{E}\cdot d\vec{r} = 0$$

Hence, electric field is directed perpendicular to the surface.

Q. 3.14. Show that the amount of work done in moving a test charge along the equipotential surface is zero.

(H.P.S.S.C.E. 1997)

Ans. Refer to section 3.10.

Q. 3.15. What the electric field is always at right angles to the equipotential surface ? Give reasons. (*P.S.S.C.E. 2001*)

Ans. The work done in moving a test charge between two points on an equipotential surface can be zero, only if electric field is at right angles to the equipotential surface.

Q. 3.16. No two equipotential surfaces intersect each other. Why ? Explain. (*P.S.S.C.E. 2001*)

Ans. Refer to section 3.10.

Q. 3.17. Draw one equipotential surface (*i*) in a uniform electric field and (*ii*) for a point charge (Q < 0). (*P.S.S.C.E. 2001*)

Ans. (*i*) In a uniform electric field, the equipotential surface is a plane at right angle to direction field [Fig. 3.10].

(*ii*) For a point charge, equipotential surface is a spherical shell with the charge lying at the centre of the shell [Fig. 3.11].

Q. 3.18. What will be the equipotential surfaces corresponding to

(*i*) a constant electric field in the Z-direction ?

(*ii*) a field that uniformly increases in magnitude but remains in the same direction (say Z-axis) ?

(*iii*) a single positive charge at the origin ?

(*iv*) a uniform grid consisting of long equally spaced parallel charged wires in a plane ?

Ans. (*i*) For a constant electric field in the Z-direction, equipotential surfaces will be planes parallel to XY- plane.

(*ii*) In this case also, the equipotential surfaces will be planes parallel to XY-plane. However, as field increases, such planes will get closer.

(*iii*) For a single positive charge at the origin, the equipotential surfaces will be concentric spherical shells having origin as their common centre.

(*iv*) Near the grid consisting of long equally spaced parallel charged wires, the equipotential surfaces will have varying shapes. At far off distances, the equipotential surfaces will be planes parallel to the grid.

Q. 3.19. The equipotential surfaces of a certain electric field are shown in Fig. 3.37. It is known that $V_1 > V_2$. Use this pattern to reproduce approximately the lines of force of this field. Also indicate the region in which the intensity of the electric field is highest.

Ans. The lines of force are everywhere perpendicular to the equipotential surfaces and are directed in the direction of decreasing potential. Likewise, for the equipotential surfaces shown in Fig. 3.37, the lines of fo will be as shown in Fig. 3.38.

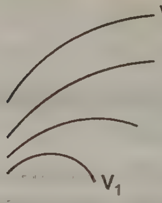

Fig. 3.37

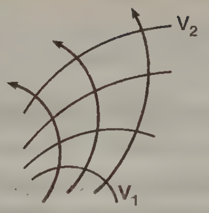

Fig. 3.38

The intensity of electric field is highest in the regi where the equipotential surfaces are closest to each othe

Q. 3.20. Distinguish between electric potential a potential energy and state the relation between these. (*P.S.S.C.E. 1996*

Ans. For definitions of electric potential and potent energy, refer to sections 3.04 and 3.12.

Electric potential due to a charge q_1 at a point P distance r is given by

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{r}$$

If another charge q_2 is placed at observation point P, th potential energy of the system of the two charges is given

$$U = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{r} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{r}\times q_2$$

= electric potential due to charge q_1 at the location of q_2 ×

Q. 3.21. What do you mean by potential energy of electric dipole, when placed in electric field ?

Ans. An electric dipole always tends to orient itself alo the direction of electric field. Work has to be done in rotati the dipole to some other orientation and this work done rotating the dipole gets stored in the dipole in the form of potential energy.

Q. 3.22. What does the negative sign in the expressi for potential energy ($U = -p\,E\cos\theta$) signify ?

Ans. While deriving the expression for potential ener the potential energy of the dipole is taken as zero, when i oriented perpendicular to the direction of the electric fie In any other orientation between $\theta = 0°$ to $\theta = 90°$, the potent energy of the dipole is less than zero and hence the negat sign.

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 3.01. 'Work done to move a charge along a closed path inside an electric field is always zero.' Use this fact to prove that it is impossible to produce an electric field in which all the lines of force would be parallel straight lines and the density of their distribution would constantly increase in a direction perpendicular to the lines of force [Fig. 3.39].

Ans. Suppose that a charge q is moved along a closed path ABCD inside the electric field [Fig. 3.40]. Since work done to move a charge q along a closed path inside an electric field is zero,

$$W_{AB} + W_{BC} + W_{CD} + W_{DA} = 0$$

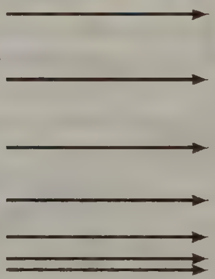

Fig. 3.39

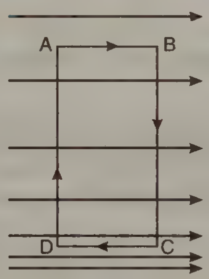

Fig. 3.40

Since electric field is perpendicular to paths BC and D $W_{BC} = W_{DA} = 0$.

$\therefore \qquad W_{AB} + 0 + W_{CD} + 0 = 0$

or $\qquad W_{AB} - = - W_{CD}$

But for the electric field shown in Fig. 3.40, work done to ve a charge along paths AB and CD can not be equal in gnitude. As the lines of force are closer to each other near path CD, intensity of electric field is more along path CD n along path AB. Therefore, work done to move the nge q along the path CD will be more than that along the h AB. Thus, work done to move a charge along a closed h cannot be zero for the electric field as shown in Fig. 3.39 l hence, it is impossible to produce an electric field shown he figure.

Q. 3.02. Prove that if the lines of force are shaped like arcs of concentric circles with their centre at point O certain section of an electric field [Fig. 3.41], the intensity the field in this section at each point is inversely portional to its distance from point O.

Ans. Consider a closed path ABCD in the electric field, h that paths AB and CD are circular arcs of radii r_1 and r_2 pectively as shown in Fig. 3.42.

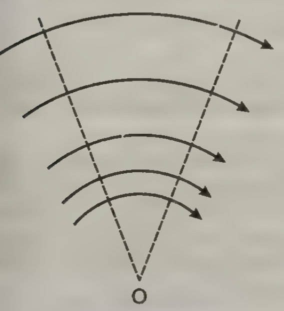

Fig. 3.41

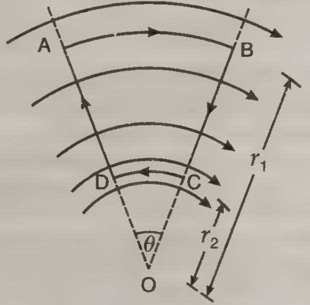

Fig. 3.42

Suppose that a charge q is moved along the path ABCD. en,

$$W_{AB} + W_{BC} + W_{CD} + W_{DA} = 0 \qquad ...(i)$$

As electric field is perpendicular to paths BC and DA,

$$W_{BC} = W_{DA} = 0$$

Therefore, equation (*i*) becomes

$$W_{AB} + W_{CD} = 0 \qquad ...(ii)$$

Let $\vec{E_1}$ and $\vec{E_2}$ be electric fields along paths AB and CD pectively. Then,

$$W_{AB} = q\,\vec{E_1} \cdot \vec{(AB)} = q\,E_1\,(AB) \cos 0°$$

$$= q\,E_1\,(AB) = q\,E_1\,(r_1\,\theta)$$

$$W_{CD} = q\,\vec{E_2} \cdot \vec{(CD)} = q\,E_2\,(CD) \cos 180°$$

$$= -q\,E_2\,(CD) = -q\,E_2\,(r_2\,\theta)$$

Substituting for W_{AB} and W_{CD} in equation (*ii*), we have

$$q\,E_1\,(r_1\,\theta) - q\,E_2\,(r_2\,\theta) = 0$$

or $\qquad \dfrac{E_1}{E_2} = \dfrac{r_2}{r_1} \quad$ or $\quad E \propto \dfrac{1}{r}$

Q. 3.03. Two point charges $+q$ and $-q$ are separated by a distance d. Where besides at infinity is the electric potential zero ?

Ans. Suppose that electric potential is zero at the point, which is at a distance r_1 from charge $+q$ and r_2 from charge $-q$. Then,

$$\frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r_1} + \frac{1}{4\pi\varepsilon_0} \cdot \frac{-q}{r_2} = 0 \quad \text{or} \quad r_1 = r_2$$

All such points for which $r_1 = r_2$ lie on a plane, which is right bisector of the line joining the two charges.

Q. 3.04. Two small charged bodies ineract in air with a force F. What will the force of interaction between these bodies be after they are placed in a dielectric of permitivity K, if their potentials are kept the same as they were in air ?

Ans. Suppose that the two charged bodies possess charges q_1 and q_2 and are placed in air at a distance r apart. The force between the two charged bodies in air is given by

$$F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2} \qquad ...(i)$$

When the charges are placed in dielectric of permitivity K, the potential due to each charged body will decrease by a factor K. In order to keep their potentials same, the charges on the two bodies should be increased K times *i.e.* the two bodies should possess charges K q_1 and K q_2 respectively. Then, the force between the two charged bodies, when placed in dielectric is given by

$$F' = \frac{1}{4\pi\varepsilon_0 K} \cdot \frac{(K q_1)(K q_2)}{r^2} = K\left(\frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}\right) \qquad ...(ii)$$

From equations (*i*) and (*ii*), it follows that

$$F' = K F$$

Q. 3.05. Two charges 2μC and −2μC are placed at points A and B 6 cm apart. (*a*) Identify an equipotential surface of the system. (*b*) What is the direction of the electric field at every point on this surface ? (*Text Question*)

Ans. Fig. 3.43 shows two charges of 2 μC and − 2 μC located at points A and B, such that AB = 6 cm.

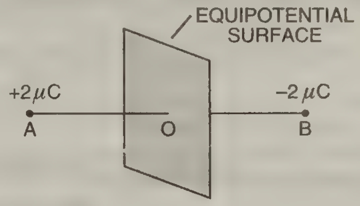

Fig. 3.43

(*a*) For the given system of two charges, the equipotential surface will be a plane normal to the line AB joining the two charges and passing through its mid-point O. On any point on this plane, potential is zero.

(*b*) The electric field is in a direction from point A to point B *i.e.* from positive charge to negative charge and normal to the equipotential surface.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. Find an expression for line integral of electric intensity. (*H.S.S.C.E. 2001*)
2. Derive a relation for the work done in moving a charge in an electric field. (*P.S.S.C.E. 1998*)
3. Show that the work done in moving a unit charge along a closed path is zero. (*H.P.S.S.C.E. 2000*)
4. Derive an expression for electric potential at a point due to a point charge. (*P.S.S.C.E. 1999 S ; C.B.S.E. 1993*)

5. Define electric potential at a point. Is it a scalar or a vector quantity ? Derive an expression for the potential at a point due to a point charge.
6. Derive an expression for the electric potential at a point along the axial line of an electric dipole. *(C.B.S.E. 2002, 2000 ; P.S.S.C.E. 2001)*
7. Define electric potential. Deduce an expression for the electric potential at a point at distance *r* from a point charge ($q > 0$). *(C.B.S.E. 2001)*
8. Find an expression for electric potential due to an electric dipole. *(H.S.S.C.E. 2001)*
9. Define potential gradient. Obtain the relation between electric field and potential gradient at a point in the electric field.
10. What do you mean by an equipotential surface ? What w be the shapes of equipotential surfaces in case of a unifor field and a point charge ? Discuss.
11. What do you mean by potential energy of the config ration of two electric charges ? Derive expression fo system of two point charges lying at distance *r*.
12. Derive expression for potential energy of a system of tv point charges and find its relation with electric potent of a charge. *(P.S.S.C.E. 2000, 199*
13. Derive an expression for the total work done in rotati an electric dipole through an angle θ in a uniform elect field. *(C.B.S.E. 199*
14. Derive an expression for the potential energy of an elect dipole in uniform electric field. *(H.S.S.E.C. 2000, 1994 ; P.S.S.C.E. 1995*

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. Show that the line integral of electric field intensity between any two points depends only on the position of these points and is independent of the path followed between these points. *(H.P.S.S.C.E. 2002 ; P.S.S.C.E. 1993)*
2. Show that work done in moving an electric charge between two points in the electric field of a point charge is independent of the path along which the charge is moved. *(P.S.S.C.E. 1992)*
3. Define potential difference between two points in an electric field. Hence, obtain expression for it.
4. Define the potential difference between two points in an electric field and derive an expression for it. Also give SI unit of potential difference. *(P.S.S.C.E. 1999 S)*
5. Define potential difference between two points in an electric field. Derive the relationship between electric field and the potential difference.
6. Show that electric potential can be represented as li integral of an electric field. *(H.S.S.C.E. 199*
7. Obtain an expression for the electrostatic potential a point in a space due to an electric dipole consisting charges $+q$ at $\left(0, 0, \frac{a}{2}\right)$ and $-q$ at $\left(0, 0, -\frac{a}{2}\right)$.
8. Obtain expression for potential energy of the configurati of three charges. Hence, generalise the result for a syste of *n* point charges.
9. Derive expression for potential energy of an electric dipo placed in a uniform electric field. *(H.P.S.S.C.E. 200*
10. What is meant by potential energy of an electric dipo when placed in an external electric field ? Show that t potential energy U of an electric dipole of dipo moment $\vec{p}$ in a uniform field $\vec{E}$ is given by

$$U = -\vec{p} \cdot \vec{E}$$

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Potential difference and Work done in moving a charge

1. 60 J of work must be done to move electric charge equal to 5 C from a point, where potential is +20 V to another point, where potential is V volt. Find the value of V. **[Ans.** 32 V]
2. 10 joule of work must be done to move a charge of – 200 C from the point A to point B.
   (*i*) Which of the two points is at higher potential ?
   (*ii*) What is the potential difference ?
   [Ans. (*i*) A ; (*ii*) 0·05 V]

Type B. On Potential due to point charges

3. The potential at a point 0·1 m from an isolated point charge is +100 volt. Find the nature and magnitude of the point charge. **[Ans.** $1{\cdot}11 \times 10^{-9}$ C (positive)]
4. What is the electric potential at the surface of an iron nucleus ? The radius of the nucleus is $4{\cdot}2 \times 10^{-15}$ m and the atomic number is 26. **[Ans.** $8{\cdot}91 \times 10^{6}$ V]
5. The electric field at a point due to a point charge is 20 N C^{-1} and the electric potential at that point is 10 J C^{-1}. Calculate the distance of the point from the charge and the mangitude of the charge. *(C.B.S.E. 1996)* **[Ans.** 0·5 m ; $5{\cdot}56 \times 10^{-10}$ C]
6. The potential at a certain distance from a point charge is 600 volt and the electric field is 200 N C^{-1}. Find
   (*i*) the distance of the point from the charge ;
   (*ii*) the magnitude of the charge. **[Ans.** 3 m ; 2×10^{-7}
7. A spherical oil drop of raidus 10^{-4} cm has on it at a certa time a charge of 40 electrons. Calculate the energy th would be required to place an additional electron on t drop. Charge on an electron = $1{\cdot}6 \times 10^{-19}$ C. **[Ans.** $9{\cdot}22 \times 10^{-21}$

Type C. On Potential due to group of charges

8. Two charges equal to + 20 μC and – 10 μC are placed points 6 cm apart. Find the value of the potential at a poi distant 4 cm on the right bisector of the line joining the tv charges. **[Ans.** $1{\cdot}8 \times 10^{6}$
9. Two tiny spheres carrying charges 1·5 μC and 2·5 μC a located 30 cm apart. Find the potential and electric field the mid-point of the line joining the two charges. **[Ans.** $2{\cdot}4 \times 10^{5}$ V, $4{\cdot}0 \times 10^{5}$ N C^{-1} (from 2·5 μC to 1·5 μC
10. Two charges of values 50 μC and 100 μC are placed a distance of 6 cm apart. Find the field and potential a point (between two charges) 2 cm from the charge of val 50 μC. **[Ans.** $5{\cdot}625 \times 10^{8}$ N C^{-1} (from 50 μC to 100 μC), $4{\cdot}5 \times 10^{7}$
11. Two point charges, each of 3×10^{-9} C located at the tv vertices of an equilateral triangle of side 20 cm. How mu work must be done to bring a charge of 10^{-9} C upto t third corner of the triangle from infinity ? **[Ans.** $2{\cdot}7 \times 10^{-7}$

12. The sides of a rectangle ABCD are 15 cm and 5 cm. Two point charges of $+2\mu$C and -5μC are placed at the corners A and C respectively [Fig. 3.44]. Calculate the work done in carrying a charge of 3 μC from point B to D. [**Ans.** 2·52 J]

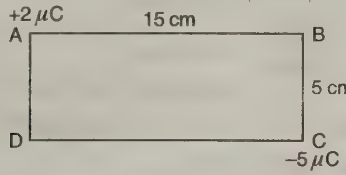

Fig. 3.44

pe D. On Potential gradient and electric field

13. A small particle carrying a negative charge of $1{\cdot}6 \times 10^{-19}$ C is suspended in equilibrium between the horizontal metal plates 5 cm apart, having a potential difference of 3000 volt across them. Find the mass of the particle. [**Ans.** $9{\cdot}8 \times 10^{-16}$ kg]

14. What is the potential gradient (in V m^{-1}) at a distance of 10^{-12} m from the centre of the platinum nucleus ? What is the potential gradient at the surface of the nucleus ? Atomic number of platinum is 78 and the radius of platinum nucleus may be taken as 5×10^{-15} m. [**Ans.** $1{\cdot}123 \times 10^{17}$ V m^{-1} ; $4{\cdot}493 \times 10^{21}$ V m^{-1}]

15. The electric potential V (x) in a region along the X-axis varies with the distance x (in metre) according to the relation $V(x) = 4x^2$. Calculate the force experienced by a 1 μC charge placed at point $x = 1$ m. (*P.S.S.C.E. 1999 S*) [**Ans.** -8×10^{-6} N]

16. In problem no. 2, if the points are 4 cm apart, what is the component of the electric field parallel to the line joining the points A and B. [**Ans.** 1·25 V m^{-1}]

pe E. On Potential energy of a system of charges

17. In the nucleus of ${}_{92}U^{238}$, two protons are at a distance of 6×10^{-15} m. Calcualte their electrostatic potential energy. [**Ans.** $3{\cdot}84 \times 10^{-14}$ J]

18. Two point charges equal to + 4 μC and + 2 μC are 12 cm apart. What is the amount of work done to bring them closer through a distance of 3 cm ? [**Ans.** 0·2 J]

19. There charges $-q$, Q and $-q$ are placed at equal distances on a straight line. If the potential energy of the system of three charges is zero, then what is the ratio of Q : q ? [**Ans.** 1 : 4]

20. Three points charges $+q$, $+2q$ and Q are placed at the three vertices of an equilateral triangle. Find the value of charge Q (in terms of q), so that electric potential energy of the system is zero. [**Ans.** $-2q/3$]

21. Find the electrostatic potential energy of the configuration of four charges $+q, -q, +q$ and $-q$ placed at the four corners A, B, C and D of a square of side r.

$$\left[\textbf{Ans. } \frac{1}{4\pi\varepsilon_0} \cdot \frac{q^2(\sqrt{2}-4)}{r}\right]$$

22. Two isolated metallic solid spheres of radii R and 2 R are charged, such that both of these have same charge density σ. The spheres are located far away from each other and connected by a thin conducting wire. Find the new charge density on the bigger sphere. (*I.I.T. 1996*) [**Ans.** $\frac{5}{6}\sigma$]

23. Two electrons are moving towards each other, each with a velocity of 10^6 m s^{-1}. What will be closest distance of approach between them. [**Ans.** $2{\cdot}53 \times 10^{-10}$ m]

Type F : On potential energy of an electric dipole

24. An electric dipole of length 2 cm is placed with its axis making an angle of 30° to a uniform electric field of 10^5 N C^{-1}. If it experiences a torque of $10\sqrt{3}$ N m, calculate (*i*) the magnitude of the charge on the dipole and (*ii*) potential energy of the dipole. (*C.B.S.E. 2000*) [**Ans.** (*i*) $\sqrt{3} \times 10^{-2}$ C (*ii*) -30 J]

25. An electric dipole consists of two opposite charges each of magnitude $6 \times 10^{-\mathcal{E}}$ coulomb separated by 6·0 cm. The dipole is placed in an external electric field of 5×10^{-5} N C^{-1}. (*i*) What maximum torque will the field exert on the dipole ? (*ii*) How much work will an external agent have to do in turning the dipole through 180°, starting from the position $\theta = 0°$? [**Ans.** (*i*) $1{\cdot}8 \times 10^{-13}$ N m ; (*ii*) $3{\cdot}6 \times 10^{-13}$ J]

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Proceed as in solved problem 3.01.
2. (*i*) Since work is done in moving a negative charge from point A to B, **point A is at higher potential.**

(*ii*) $V_A - V_B = \frac{10}{200} = \mathbf{0{\cdot}05\ V}$

3. Now, $V = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r}$

or $q = 4\pi\varepsilon_0 r V = \frac{0 \cdot 1 \times 100}{9 \times 10^9} = \mathbf{1{\cdot}11 \times 10^{-9}\ C\ (positive)}$

4. Proceed as in solved problem no. 3.02.
5. Proceed as in solved problem no. 3.05.
6. Proceed as in solved problem no. 3.05.
7. Charge on drop, $q = 40\,e = 40 \times 1{\cdot}6 \times 10^{-19} = 6{\cdot}4 \times 10^{-18}$ C

radius of drop, $r = 10^{-4}$ cm $= 10^{-6}$ m

Potential at the surface of the drop,

$$V = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r} = \frac{9 \times 10^9 \times 6 \cdot 4 \times 10^{-18}}{10^{-6}} = 5{\cdot}76 \times 10^{-2}\ \text{V}$$

Energy required to place an additional electron on the drop,

$W = V \times e = 5{\cdot}76 \times 10^{-2} \times 1{\cdot}6 \times 10^{-19} = \mathbf{9{\cdot}22 \times 10^{-21}\ J}$

8. Here, $q_A = +20\ \mu\text{C} = 20 \times 10^{-6}$ C,

$q_B = -10\ \mu\text{C} = -10 \times 10^{-6}$ C,

AB = 6 cm, OP = 4 cm

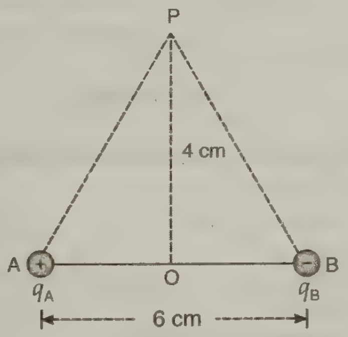

Fig. 3.45

$\therefore$ $AP = BP = \sqrt{3^2 + 4^2} = 5\ \text{cm} = 0{\cdot}05$ m

Potential at point P, $V = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A}{AP} + \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_B}{BP}$

$$= \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A + q_B}{AP} = \frac{9 \times 10^9 \times (20 \times 10^{-6} - 10 \times 10^{-6})}{0 \cdot 05}$$

$= \mathbf{1{\cdot}8 \times 10^6\ V}$

9. Here, $q_A = 1{\cdot}5\ \mu C = 1{\cdot}5 \times 10^{-6}\ C$, $q_B = 2{\cdot}5\ \mu C = 2{\cdot}5 \times 10^{-6}\ C$

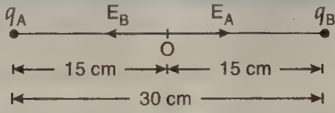

Fig. 3.46

Potential at point O, $V = \dfrac{1}{4\pi\varepsilon_0}\cdot\left(\dfrac{q_A}{OA}+\dfrac{q_B}{OB}\right)$

$= \mathbf{2{\cdot}4 \times 10^5\ V}$

Electric field at point O, $E = E_B - E_A$ $(\because E_B > E_A)$

or $E = \dfrac{1}{4\pi\varepsilon_0}\left(\dfrac{q_B}{OB^2}-\dfrac{q_A}{OA^2}\right) = \mathbf{4\times10^5\ N\ C^{-1}}$ **(along OA)**

10. Proceed as in problem no. 9.

11. Suppose that charges q_A and q_B are placed at corners A and B of an equilateral Δ ABC of side r.
Here, $q_A = q_B = 3 \times 10^{-9}$ C and $r = 20$ cm $= 0{\cdot}2$ m
Potential at the corner C due to charges q_A and q_B,

$$V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A}{AC} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_B}{BC} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_A+q_B}{r}$$

$$= 9\times10^9 \times \frac{3\times10^{-9}+3\times10^{-9}}{0{\cdot}2} = 270\ \text{V}$$

Therefore, work done to bring charge of 10^{-9} C from infinity to corner C,

$W = V \times q = 270 \times 10^{-9} = \mathbf{2{\cdot}7 \times 10^{-7}\ J}$

12. $$V_B = \frac{1}{4\pi\varepsilon_0}\cdot\left(\frac{q_A}{AB}+\frac{q_C}{CB}\right)$$

$$= 9\times10^9\left(\frac{2\times10^{-6}}{0{\cdot}15}+\frac{-5\times10^{6}}{0{\cdot}05}\right) = -78\times10^4\ \text{V}$$

$$V_D = \frac{1}{4\pi\varepsilon_0}\cdot\left(\frac{q_A}{AD}+\frac{q_C}{CD}\right)$$

$$= 9\times10^9\left(\frac{2\times10^{-6}}{0{\cdot}05}+\frac{-5\times10^{-6}}{0{\cdot}15}\right) = +6\times10^4\ \text{V}$$

Work done to move 3 μC charge from point B to D,
$W = (V_D - V_B) \times q = [6 \times 10^4 - (-78 \times 10^4)] \times 3 \times 10^{-6}$
$= \mathbf{2{\cdot}52\ J}$

13. $E = \dfrac{V}{d} = \dfrac{3000}{5\times10^{-2}} = 6\times10^4\ \text{V m}^{-1}$

As the charged particle remains suspended,

$qE = mg$ or $m = \dfrac{qE}{g} = \dfrac{1{\cdot}6\times10^{-19}\times6\times10^4}{9{\cdot}8}$

$= \mathbf{9{\cdot}8 \times 10^{-16}\ kg}$

14. Here, $q = +Ze = 78 \times 1{\cdot}6 \times 10^{-19}$
Potential gradient at a point is numerically equal to electric field at that point *i.e.*

$$\frac{dV}{dr} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}$$

$$\therefore \quad \frac{dV}{dr}\ (\text{at } r = 10^{-12}\ \text{m}) = \frac{9\times10^9\times78\times1{\cdot}6\times10^{-19}}{(10^{-12})^2}$$

$= \mathbf{1{\cdot}123 \times 10^{17}\ V\ m^{-1}}$

Similarly, $\dfrac{dV}{dr}$ (at $r = 5 \times 10^{-15}$ m) $= \mathbf{4{\cdot}493 \times 10^{21}\ V\ m^{-1}}$

15. $V(x) = 4x^2$

Now, $E = -\dfrac{dV}{dx} = -\dfrac{d}{dx}(4x^2) = -8x$

$\therefore$ E (at $x = 1$ m) $= -8 \times 1 = -8$ N C^{-1} (or V m^{-1})

Force experienced by the 1 μC charge,
$F = qE = 10^{-6} \times (-8) = \mathbf{-8 \times 10^{-6}\ N}$

16. Here, $dV = V_A - V_B = 0{\cdot}05$ V and $dr = 4$ cm $= 0{\cdot}04$ m

Now, $E = \dfrac{dV}{dr}$ (in magnitude)

$= \dfrac{0{\cdot}05}{0{\cdot}04} = \mathbf{1{\cdot}25\ V\ m^{-1}}$

17. $$U = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{r} = \frac{9\times10^9\times1{\cdot}6\times10^{-19}\times1{\cdot}6\times10^{-19}}{6\times10^{-15}}$$

$= \mathbf{3{\cdot}84 \times 10^{-14}\ J}$

18. Here, $q_1 = 4\ \mu C = 4 \times 10^{-6}$ C and $q_2 = 2\ \mu C = 2 \times 10^{-6}$ C

Now, $U = \dfrac{1}{4\pi\varepsilon_0}\cdot\dfrac{q_1 q_2}{r}$

When at r = 12 cm :

$$U_1 = \frac{9\times10^9\times4\times10^{-6}\times2\times10^{-6}}{0{\cdot}12} = 0{\cdot}6\ \text{J}$$

When at r = 12 − 3 i.e. 9 cm :

$$U_2 = \frac{9\times10^9\times4\times10^{-6}\times2\times10^{-6}}{0{\cdot}09} = 0{\cdot}8\ \text{J}$$

Therefore, work done,
$W = U_2 - U_1 = 0{\cdot}8 - 0{\cdot}6 = \mathbf{0{\cdot}2\ J}$

19. Suppose that charges $-q$, Q and $-q$ are placed at poin A, B and C on a straight line, such that AB = BC = r.

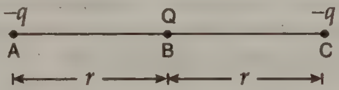

Fig. 3.47

Then, $\dfrac{1}{4\pi\varepsilon_0}\left[\dfrac{(-q)Q}{AB}+\dfrac{(-q)(-q)}{AC}+\dfrac{Q(-q)}{BC}\right] = 0$

or $-\dfrac{Q}{r}+\dfrac{q}{2r}-\dfrac{Q}{r} = 0$ or $\dfrac{2Q}{r} = \dfrac{q}{2r}$

or $\dfrac{Q}{q} = \dfrac{1}{4}$

20. Suppose that charges $+q$, $+2q$ and Q are placed at corne A, B and C of an equilateral ΔABC of side r. Then,

$$\frac{1}{4\pi\varepsilon_0}\left[\frac{q(2q)}{r}+\frac{qQ}{r}+\frac{(2q)Q}{r}\right] = 0$$

or $2q + Q + 2Q = 0$ or $Q = -2q/3$

21. Suppose that charges q_A, q_B, q_C and q_D are placed at t four corners A, B, C and D of a square of each side r.
Here, $q_A = +q$, $q_B = -q$, $q_C = +q$ and $q_D = -q$

$$U = \frac{1}{4\pi\varepsilon_0}$$

$$\times\left[\frac{q_A q_B}{AB}+\frac{q_A q_C}{AC}+\frac{q_A q_D}{AD}+\frac{q_B q_C}{BC}+\frac{q_B q_D}{BD}+\frac{q_C q_D}{CD}\right.$$

$$= \frac{1}{4\pi\varepsilon_0}\left[-\frac{q^2}{r}+\frac{q^2}{\sqrt{2}r}-\frac{q^2}{r}-\frac{q^2}{r}+\frac{q^2}{\sqrt{2}r}-\frac{q^2}{r}\right]$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2(\sqrt{2}-4)}{r}$$

22. Let σ be charge density of the two spheres. Then,

$q_1 = 4\pi R^2\sigma$ and $q_2 = 4\pi(2R)^2\sigma = 16\pi R^2\sigma$

Let q_1' and q_2' be charges on the two spheres, when th are connected with a wire. Then,

$q_1' + q_2' = q_1 + q_2$ ...

Since the two spheres are at same potential,

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1'}{R} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_2'}{2R} \quad \text{and} \quad q_1' = \frac{q_2'}{2}$$

Substituting for q_2' in equation (*i*), we have

$$\frac{q_2'}{2} + q_2' = q_1 + q_2 \quad \text{or} \quad q_2' = \frac{2}{3}(q_1 + q_2)$$

or $$q_2' = \frac{2}{3}(4\pi R^2\sigma + 16\pi R^2\sigma) = \frac{40\pi R^2\sigma}{3}$$

Therefore, new charge density of the bigger sphere,

$$\sigma' = \frac{q_2'}{4\pi(2R)^2} = \frac{40\pi R^2\sigma}{3\times16\pi R^2} = \frac{5}{6}\sigma$$

23. The electrons will approach each other to a distance r_0 (closest distance), where their kinetic energy will become zero. It will appear as their potential energy. Therefore,

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{e\times e}{r_0} = \frac{1}{2}mv^2 + \frac{1}{2}mv^2$$

or $$r_0 = \frac{1}{4\pi\varepsilon_0}\cdot\frac{e^2}{mv^2} = \frac{9\times10^9\times(1\cdot6\times10^{-19})^2}{9\cdot1\times10^{-31}\times(10^6)^2}$$

$$= \mathbf{2{\cdot}53\times10^{-10}\ m}$$

24. **(*i*)** $\tau = pE\sin\theta$

or $$p = \frac{\tau}{E\sin\theta} = \frac{10\sqrt{3}}{10^5\sin30^\circ} = 2\sqrt{3}\times10^{-4}\ \text{C m}$$

Now, $$q = \frac{p}{2a} = \frac{2\sqrt{3}\times10^{-4}}{2\times10^{-2}} = \sqrt{3}\times10^{-2}\ \text{C}$$

(*ii*) $U = -pE\cos\theta = -2\sqrt{3}\times10^{-4}\times10^5\times\cos30^\circ = \mathbf{-30\ J}$

25. Proceed as in solved problem no. 3.17.

CHAPTER
4

Gauss's Theorem

4.01. AREA VECTOR – A MATHEMATICAL NOTE

In many problems, area of a surface is treated as a vector. An area element dS is represented by vector $\vec{dS}$, such that the arrow respresenting the area vector $\vec{dS}$ is perpendicular to the area element [Fig. 4.01.]. The length of the area vector $\vec{dS}$ represents the magnitude of the area element dS. In case $\hat{n}$ is a unit vector along normal to the area element dS, then

$$\vec{dS} = dS\,\hat{n} \qquad \text{...(4.01)}$$

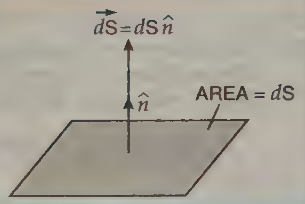

Fig. 4.01

Note. Conventionally, the area vector representing an area element of a closed surface enclosing a volume is assigned direction, such that the area vector is directed along the normal pointing outwards from the closed surface.

4.02. ELECTRIC FLUX

The electric flux through a surface held inside an electric field represents the total number of electric lines of force crossing the surface in a direction normal to the surface.

Electric flux is a ***scalar quantity*** and is denoted by ϕ*.

In fact, flux is property of a vector field and likewise electric flux is associated with electric field.

Relation between electric field intensity and electric flux. Suppose that a surface having area S is placed inside electric field of intensity $\vec{E}$ as shown in Fig. 4.02. In order to find the electric flux through the surface of area S, consider a small area element dS of the surface S. The elementary area dS can be represented by a vector $\vec{dS}$, which is directed along normal to the area element dS. Suppose that electric field $\vec{E}$ makes an angle θ with the area vector $\vec{dS}$. Then, component of electric field along normal to the area element dS *i.e.* along area vector $\vec{dS}$ is given by

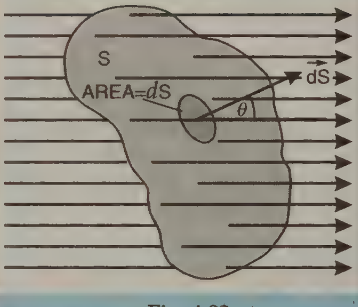

Fig. 4.02

$$E_n = E\cos\theta$$

Hence, electric flux crossing the area element dS in a direction along normal to it given by

$$d\phi = E_n\, dS = (E\cos\theta)\, dS$$

or
$$d\phi = \vec{E}\cdot\vec{dS} \qquad \text{...(4.02)}$$

The electric flux through the whole surface S can be found by integrating the above over the whole surface S. Therefore, total electric flux through the surface S is given by

$$\phi = \int_S \vec{E}\cdot\vec{dS} = \int_S E_n\, dS \qquad \text{...(4.03)}$$

Thus, *electric flux linked with a surface in an electric field may be defined as the surface integral of the electric field over that surface.*

The unit of electric flux is **N m^{-2} C^{-1}**.

Self-test Question

Show that the unit of electric flux
N m^{-2} C^{-1}.

Note. In case the surface S is a closed surface, then the total electric flux through the closed surface is given by

$$\Phi = \oint_S \vec{E}\cdot\vec{dS} = \oint_S E_n\, dS \qquad \text{...(4.04)}$$

---

* The electric flux through a surface is denoted by ϕ, while the electric flux through a closed surface is denoted by Φ.

4.03. GAUSS'S THEOREM

It states that *the total electric flux through a closed surface enclosing a charge is equal* $\frac{1}{\varepsilon_0}$ *times the magnitude of the charge enclosed.*

Here, ε_0 is the absolute permittivity of the free space.

If a closed surface S encloses an electric charge q, then according to Gauss's eorem, the total electric flux through the closed surface is given by

$$\Phi = \frac{q}{\varepsilon_0} \qquad \text{...(4.05)}$$

By definition, the total electric flux through the closed surface S is given by

$$\Phi = \oint_S \vec{E} \cdot \vec{dS},$$

here $\vec{E}$ is electric field at the area element $\vec{dS}$.

Therefore, Gauss's theorem may be expressed as

$$\oint_S \vec{E} \cdot \vec{dS} = \frac{q}{\varepsilon_0} \qquad \text{...(4.06)}$$

Hence, Gauss's theorem may also be stated as below :

If a closed surface encloses a charge, then surface integral of the electric field (due to e enclosed charge) over the closed surface is equal to $\frac{1}{\varepsilon_0}$ *times the charge enclosed.*

4.04. TO PROVE GAUSS'S THEOREM (For a spherically symmetric closed surface)

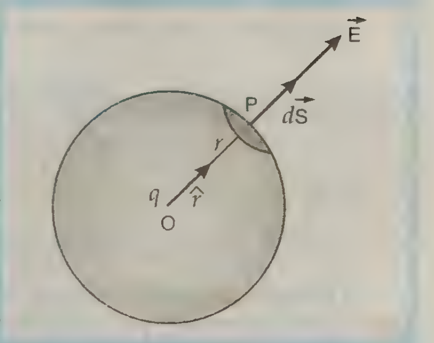

Fig. 4.03

Consider that a point electric charge q is situated at the centre of a sphere of dius r. Let $\vec{E}$ be the electric field at any point P on the surface of the sphere [Fig. 03]. Then, according to Coulomb's law,

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\,\hat{r},$$

here $\hat{r}$ is unit vector along the line OP.

Consider a small area element $\vec{dS}$ (shown shaded) around the point P. Since e small area element is located on the surface of the sphere, the area vector $\vec{dS}$ will so be along OP *i.e.* in the direction of unit vector $\hat{r}$. Therefore, electric flux through ea element $\vec{dS}$ is given by

$$d\phi = \vec{E} \cdot \vec{dS} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\,\hat{r} \cdot \vec{dS} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\,(1)\,(dS)\cos 0^\circ$$

or

$$d\phi = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\,dS$$

Therefore, electric flux through the closed surface of the sphere,

$$\Phi = \oint_S d\phi = \oint_S \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\,dS = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2} \oint_S dS$$

Now, $\oint_S dS$ = surface area of the sphere of radius $r = 4\pi r^2$

$$\therefore \qquad \Phi = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2} \times 4\pi r^2 = \frac{q}{\varepsilon_0}$$

It proves the Gauss's theorem in electrostatics.

Note. Gauss's theorem has been proved above in a special case, when the charge ies at the centre of a sphere. In fact, the theorem holds for a closed surface of any ape.

4.05. GAUSSIAN SURFACE

The expression for electric field intensity can be obtained by applying oulomb's law only in simple cases. In the situations, where Coulomb's law or inciple of superposition cannot be applied to calculate the electric field, the same achieved by using Gauss's law. For this, one has to evaluate the surface integral.

So that surface integral can be evaluated easily, a closed surface is chosen cleverly around the charge distribution. The surface so chosen is called the ***gaussian surface***.

Thus, *gaussian surface around a charge distribution (may be a point charge, a line charge, a surface charge or a volume change) is a closed surface, such that electric field intensity at all the points on the surface is same and the electric flux through the surface is along the normal to the surface.*

4.06. TO DEDUCE COULOMB'S LAW FROM GAUSS'S THEOREM

Consider that two point charges q_1 and q_2 are placed at points A and B at a distance r apart in vacuum. Let E be the magnitude of electric field at the location of point charge q_2 due to the charge q_1. Then, force experienced by the point charge q_2 due to the electric field of the charge q_1,

$$F = q_2 E \qquad ...(4.07)$$

To find E, draw a spherical surface of radius r with point A as the centre as shown in Fig. 4.04. According to Gauss's theorem, the total electric flux through the spherical gaussian surface is given by

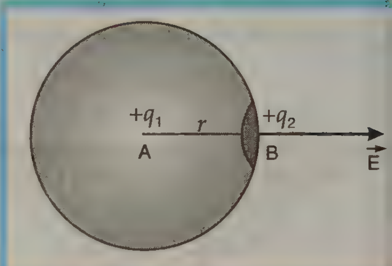

Fig. 4.04

$$\oint_S \vec{E} \cdot \vec{dS} = \frac{q_1}{\varepsilon_0}$$

$$\therefore \quad \frac{q_1}{\varepsilon_0} = \oint_S \vec{E} \cdot \vec{dS} = \oint E\, dS \qquad (\because \vec{E} \parallel \vec{dS})$$

Now, the value of E (magnitude of electric field) is same at all the points on the spherical surface *i.e.* E is constant. Therefore,

$$\frac{q_1}{\varepsilon_0} = E \oint dS$$

Now, $\oint dS = 4\pi r^2$ (surface area of the spherical guassian surface of radius r)

$$\therefore \quad \frac{q_1}{\varepsilon_0} = E \times 4\pi r^2$$

or

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1}{r^2} \qquad ...(4.08)$$

From equations (4.07) and (4.08), we have

$$F = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}$$

It is the mathematical form of Coulomb's law in electrostatics.

4.07. ELECTRIC FIELD DUE TO A LINE CHARGE

Consider a thin infinitely long straight line charge having a uniform linear charge density λ placed along YY′. By symmetry, it follows that electric field due to line charge at a distance r in any plane at right angles to the line charge is of the same magnitude and is directed radially outward. To find electric field due to line charge at point P distant r from it, draw a cylindrical surface of radius r and length l about the line charge as its axis [Fig. 4.05]. This cylindrical surface may be treated as the gaussian surface for the line charge.

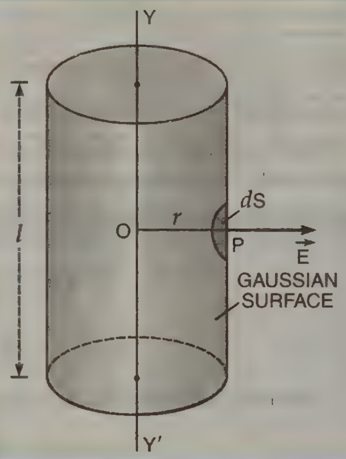

Fig. 4.05

Let us now calculate the electric flux that crosses the Gaussian surface from the charge enclosed by the gaussian surface. Since electric lines of force are parallel to end faces (circular caps) of the cylinder, there is no component of field along the normal to the end faces. The electric flux crosses only through the curved surface of the cylinder, as the electric field due to the line charge is normal to the curved surface. If E is the magnitude of electric field at point P, then electric flux through the gaussian surface is given by

$\Phi = E \times$ area of the curved surface of a cylinder of radius r and length l

or

$$\Phi = E \times 2\pi r l \qquad ...(4.09)$$

According to Gauss's theorem, we have

$$\Phi = \frac{q}{\varepsilon_0}$$

Now, charge enclosed by the gaussian surface, $q = \lambda l$

$$\therefore \quad \Phi = \frac{\lambda l}{\varepsilon_0} \qquad ...(4.10)$$

Key point

The electric field due to a line charge fall off with distance as $1/r$.

From equations (4.09) and (4.10), we have

$$E \times 2\pi r l = \frac{\lambda l}{\varepsilon_0}$$

or $$E = \frac{1}{2\pi\varepsilon_0} \cdot \frac{\lambda}{r} \qquad ...(4.11)$$

In contrast to electric field due to a point charge (which decreases inversely as he square of the distance from the charge), the field due to a line charge falls off as $\frac{1}{r}$.

Note. The above discussion can be easily extended to find electric field due to uniformly charged cylindrical shell. The same has been deduced in section 5.08 cylindrical capacitor) in the next chapter.

4.08. ELECTRIC FIELD DUE TO AN INFINITE PLANE SHEET OF CHARGE

Consider an infinite thin plane sheet* of positive charge having a uniform urface charge density σ on both sides of the sheet. By symmetry, it follows that the lectric field is perpendicular to the plane sheet of charge and is directed in outward irection. To find electric field due to the plane sheet of charge at any point P distant from it, draw a cylinder of area of cross-section A through the point P as the aussian surface [Fig. 4.06]. Since electric lines of force are parallel to the curved urface of the cylinder, the flux due to electric field of the plane sheet of charge passes nly through the two circular caps of the cylinder. If E is the magnitude of electric eld at point P, then electric flux crossing through the gaussian surface is given by

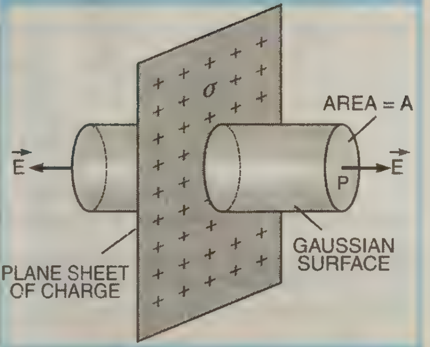

Fig. 4.06

$$\Phi = E \times \text{area of the end faces (circular caps) of the cylinder}$$

or $$\Phi = E \times 2A \qquad ...(4.12)$$

According to Gauss's theorem, we have

$$\Phi = \frac{q}{\varepsilon_0}$$

Here, the charge enclosed by the gaussian surface, $q = \sigma A$

∴ $$\Phi = \frac{\sigma A}{\varepsilon_0} \qquad ...(4.13)$$

From equations (4.12) and (4.13), we have

$$E \times 2A = \frac{\sigma A}{\varepsilon_0}$$

or $$E = \frac{\sigma}{2\varepsilon_0} \qquad ...(4.14)$$

Thus, we find that the magnitude of the electric field at a point due to an infinite lane sheet of charge is independent of its distance from the sheet of charge.

Key point

The magnitude of electric field due to an infinite plane sheet of charge is independent of the distance of the observation point from the sheet of charge.

Note. In case of an infinite plane conductor having finite thickness, the gaussian urface will include charge σ × 2A (σ A on each side of the conductor). Therefore, n such a case,

$$E \times 2A = \frac{\sigma \times 2A}{\varepsilon_0}$$

or $$E = \frac{\sigma}{\varepsilon_0} \qquad ...(4.15)$$

Watch out !

In a sheet of charge, the same charge shows up on its two sides. Since a plane charge conductor has a finite thickness, different charges show up on its two sides !

4.09. ELECTRIC FIELD DUE TO TWO INFINITE PLANE PARALLEL SHEETS OF CHARGE

Consider two infinite plane parallel sheets of charge A and B, having surface harge densities equal to σ_A and σ_B respectively. The two sheets divide the space nto three regions namely region I lying to the left of sheet A, region II between the heets A and B and region III to the right of sheet B as shown in Fig. 4.07.

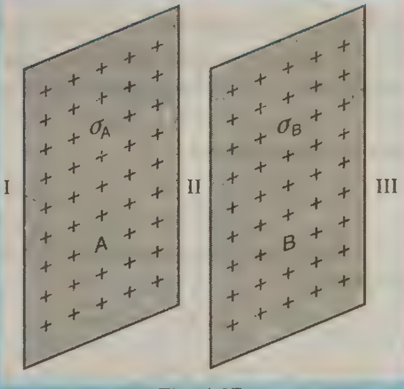

Fig. 4.07

(*i*) ***In region I.*** The electric fields due to both the sheets of charge will be from ight to left (opposite to the direction, in which distances are measured as positive). ince electric field due to a sheet of charge is given by equation (4.14), the electric ield due to sheets A and B in region I will be

$$E = \left(-\frac{\sigma_A}{2\varepsilon_0}\right) + \left(-\frac{\sigma_B}{2\varepsilon_0}\right)$$

---

*In a sheet of charge, the same charge shows up on its two sides.

or $$E = -\frac{1}{2\varepsilon_0}(\sigma_A + \sigma_B) \qquad ...(4.16)$$

(ii) In region II. The electric field due to sheet of charge A will be from left to right (along positive direction) and that due to sheet of charge B will be from right to left (along negative direction). Therefore, in region II,

$$E = \frac{\sigma_A}{2\varepsilon_0} + \left(-\frac{\sigma_B}{2\varepsilon_0}\right)$$

or $$E = -\frac{1}{2\varepsilon_0}(\sigma_A - \sigma_B) \qquad ...(4.17)$$

(iii) In region III. The electric fields due to both the sheets of charge will be from left to right *i.e.* along positive direction. Therefore, in region III,

$$E = \frac{\sigma_A}{2\varepsilon_0} + \frac{\sigma_B}{2\varepsilon_0}$$

$$E = \frac{1}{2\varepsilon_0}(\sigma_A + \sigma_B) \qquad ...(4.18)$$

Special case. If $\sigma_A = \sigma$ and $\sigma_B = -\sigma$, then it follows that electric field is zero in regions I and III, while in the region II, the electric field is given by

$$E = \frac{1}{2\varepsilon_0} + [\sigma - (-\sigma)]$$

or $$E = \frac{\sigma}{\varepsilon_0} \qquad ...(4.19)$$

Thus, in case of two infinite plane sheets of charge having equal and opposite surface charge densities, the field is non-zero only in the space between the two sheets and it is constant *i.e.* uniform in this region. Further, the field is independent of the distance between the infinite plane sheets of charge.

Note. In case two infinite plane charged conductors of finite thickness are placed parallel to each other, the equations (4.16), (4.17) and (4.18) will modify to :

$$E = -\frac{1}{\varepsilon_0}(\sigma_A + \sigma_B) \qquad ...\text{in region I}$$

$$E = \frac{1}{\varepsilon_0}(\sigma_A + \sigma_B) \qquad ...\text{in region II}$$

and $$E = \frac{1}{\varepsilon_0}(\sigma_A + \sigma_B) \qquad ...\text{in region III}$$

4.10. ELECTRIC FIELD DUE TO A UNIFORMLY CHARGED SPHERICAL SHELL

Consider a thin spherical shell of radius R and centre O. Let q be the charge on the spherical shell. Let us find electric field at point P distant r from the centre of the spherical shell.

(a) When point P lies outside the spherical shell. Draw the gaussian surface through point P. It will be a spherical shell of radius r and centre O [Fig. 4.08].

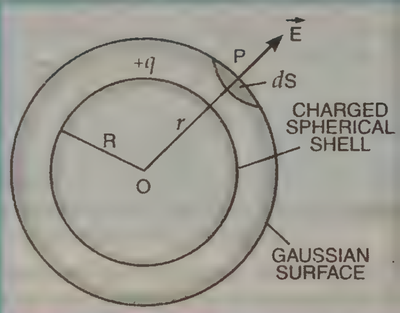

Fig. 4.08

Let $\vec{E}$ be the electric field at point P due to charge q on the spherical shell.

It is evident that the field due to charged spherical shell is radial and spherically symmetric. At every point on the surface of shell, the field has same magnitude and is along normal to the surface. Therefore, total flux through the gaussian surface is given by

$$\Phi = \oint_S \vec{E} \cdot d\vec{S} = \oint_S E\, dS = E \oint_S dS = E \cdot 4\pi r^2$$

Since the charge enclosed by the gaussian surface is q, according to the Gauss's theorem,

$$E \cdot 4\pi r^2 = \frac{q}{\varepsilon_0}$$

or $$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2} \quad (\text{for } r > R) \qquad ...(4.20)$$

From equation (4.20), it follows that for the points outside the charged spherical shell, the shell behaves as if the charge on the shell were concentrated at its centre.

Key point

For points outside a charged spherical shell, the shell behaves as if the charge on it were concentrated at its centre.

The above result for electric field due to a charged spherical shall can also be xpressed in terms of its surface density as explained below :

If σ is uniform surface charge density of the spherical shell, then

$$q = 4\pi R^2 \sigma$$

Substituting for q in equation (4.20), we have

$$E = \frac{\sigma}{\varepsilon_0} \cdot \frac{R^2}{r^2} \qquad (\text{for } r > R) \qquad \text{...(4.21)}$$

Watch out !

When a conducting sphere is charged, the charge appears on its outer surface. A solid sphere of charge is built of charges, which are distributed uniformly inside it and stay there as such !

(b) When point P lies on the surface of spherical shell. The gaussian surface hrough point P will just enclose the charged spherical shell. Therefore, according o Gauss's theorem,

$$E \,.\, 4\pi R^2 = \frac{q}{\varepsilon_0}$$

or
$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{R^2} \qquad (\text{for } r = R) \qquad \text{...(4.22)}$$

Since $q = 4\pi R^2 \sigma$, the equation (4.22) becomes

$$E = \frac{\sigma}{\varepsilon_0} \qquad (\text{for } r = R) \qquad \text{...(4.23)}$$

(c) When point P lies inside the spherical shell. In such a case, the gaussian urface through point P will not enclose any charge and hence according to the Gauss's theorem,

$$E \,.\, 4\pi r^2 = \frac{0}{\varepsilon_0}$$

or
$$E = 0 \qquad (\text{for } r < R) \qquad \text{...(4.24)}$$

Thus, at a point inside the charged spherical shell, electric field is zero.

Key point

At a point inside a charged spherical shell, electric field is zero.

4.11. ELECTRIC FIELD DUE TO A SOLID SPHERE OF CHARGE

Consider an isolated sphere of charge q having radius R. Suppose we have to alculate electric field at point P at a distance r from its centre O.

(a) When point P lies outside the sphere of charge : Draw the gaussian surface hrough point P so as to enclose the sphere of charge. The gaussian surface is a pherical shell of radius r and centre O [Fig. 4.09].

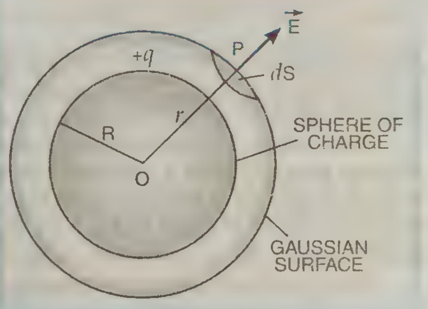

Fig. 4.09

Let $\vec{E}$ be the electric field at point P due to the sphere of charge q. It is evident hat the field due to the sphere charge is spherically symmetric. At every point on he surface of the sphere, the field has same magnitude and is along normal to the urface.

Therefore, total flux through the gaussian surface is given by

$$\Phi = \oint_S \vec{E} \,.\, \vec{dS} = \oint_S E \,.\, \vec{dS} = E \oint_S dS = E \,.\, 4\pi r^2$$

According to Gauss's theorem,

$$E \,.\, 4\pi r^2 = \frac{q}{\varepsilon_0}$$

or
$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2} \qquad (\text{for } r > R) \qquad \text{...(4.25)}$$

It is the same as that at a distance r from a point charge q. It implies that for points outside the sphere of charge, the sphere behaves as if all the charge on the sphere were concentrated at its centre. If ρ is the uniform volume charge density of the sphere of charge, then

Key point

For points outside the sphere of charge, the sphere also behaves as if charge on the sphere were concentrated at its centre.

$$q = \frac{4}{3}\pi R^3 \rho$$

Substituting for q in equation (4.25), we have

$$E = \frac{\rho}{\varepsilon_0} \cdot \frac{R^3}{3r^2} \qquad (\text{for } r > R) \qquad \text{...(4.26)}$$

(b) When point P lies at the surface of the sphere of charge : In such a case, the rea of the gaussian surface is equal to the surface area of the sphere of charge *i.e.* equal to $4\pi R^2$. If E is the electric field at point P on the surface of the sphere of charge, hen according to Gauss's theorem,

$$E \,.\, 4\pi R^2 = \frac{q}{\varepsilon_0}$$

or $$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{R^2} \qquad \text{(for } r = R\text{)} \qquad ...(4.27)$$

Since $q = \frac{4}{3}\pi R^3 \rho$, equation (4.27) becomes

$$E = \frac{\rho R}{3\varepsilon_0} \qquad \text{(for } r = R\text{)} \qquad ...(4.28)$$

(c) When point P lies inside the sphere of charge : In such a case, the gaussian surface is *a* spherical shell, whose centre is O and radius is r (= OP) as shown in Fig. 4.10. If q' is charge enclosed by the gaussian surface, then

$$E \,.\, 4\pi r^2 = \frac{q'}{\varepsilon_0}$$

or $$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q'}{r^2} \qquad \text{(for } r < R\text{)} \qquad ...(4.29)$$

Now, $$q' = \frac{q}{\frac{4}{3}\pi R^3} \times \frac{4}{3}\pi r^3 = q\frac{r^3}{R^3}$$

Substituting for q' in equation (4.29), we have

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q\,r}{R^3} \qquad \text{(for } r < R\text{)} \qquad ...(4.30)$$

Since $q = \frac{4}{3}\pi R^3 \rho$, the equation (4.30) becomes

$$E = \frac{\rho\, r}{3\varepsilon_0} \qquad \text{(for } r < R\text{)} \qquad ...(4.31)$$

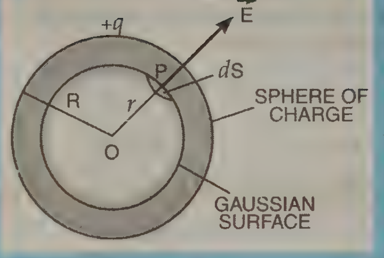

Fig. 4.10

SOLVED NUMERICAL PROBLEMS

Type A. On Electric Flux

Problem 4.01. A rectangular surface of sides 10 cm and 15 cm is placed inside a uniform electric field of 25 V m^{-1}, such that normal to the surface makes an angle of 60° with the direction of electric field. Find the flux of the electric field through the rectangular surface.

Sol. The flux through the rectangular surface is given by

$$\phi = \vec{E} \,.\, \vec{\Delta S} = E\, \Delta S \cos\theta$$

Here, $E = 25 \text{ V m}^{-1}$;

$\Delta S = 10 \times 15 = 150 \text{ cm}^2 = 150 \times 10^{-4} \text{ m}^2$

and $\theta = 60°$

$\therefore$ $\phi = 25 \times 150 \times 10^{-4} \cos 60°$

$= \mathbf{0 \cdot 1875 \text{ N m}^2 \text{ C}^{-1}}$

Problem 4.02. Consider a uniform electric field $\vec{E} = 3 \times 10^3 \,\hat{i}\, \text{N C}^{-1}$. (*a*) What is the flux of this field through a square of 10 cm on a side, whose plane is parallel to the YZ-plane ? (*b*) What is the flux through the same square, if the normal to its plane makes a 60° angle with the X-axis ? (*Text Problem*)

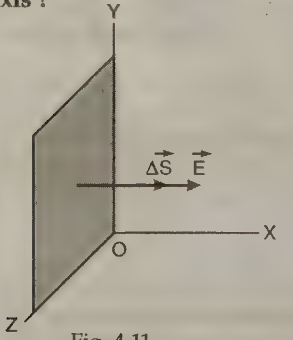

Fig. 4.11

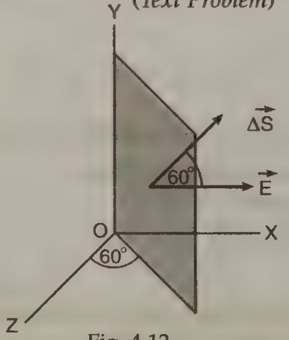

Fig. 4.12

Sol. (*a*) The area of a surface can be represented as a vector along normal to the surface [Fig. 4.11].

Here, $\vec{E} = 3 \times 10^3 \,\hat{i}\, \text{N C}^{-1}$

Area of the square, $\Delta S = 10 \times 10 = 100 \text{ cm}^2 = 10^{-2} \text{ m}^2$

Since normal to the square is along X-axis, we have

$$\vec{\Delta S} = 10^{-2}\, \hat{i} \text{ m}^2$$

Electric flux through the square,

$$\phi = \vec{E} \,.\, \vec{\Delta S} = (3 \times 10^3\, \hat{i}) \,.\, (10^{-2}\, \hat{i})$$

$$= \mathbf{30 \text{ N m}^2 \text{ C}^{-1}}$$

(*b*) Here, angle between normal to the square *i.e.* area vector and the electric field is 60° [Fig. 4.12]. Therefore,

$$\phi = \vec{E} \,.\, \vec{\Delta S} = E\, \Delta S \cos 60° = 3 \times 10^3 \times 10^{-2} \times 0{\cdot}5$$

$$= \mathbf{15 \text{ N m}^2 \text{ C}^{-1}}$$

Type B. On Gauss's Theorem

Problem 4.03. Calculate the number of electric lines of force originating from a charge of 1 C.

Given, $\varepsilon_0 = 8 \cdot 854 \times 10^{-12} \text{ C}^2 \text{ N}^{-1} \text{ m}^{-2}$.

Sol. Here, $q = 1 \text{ C}$; $\varepsilon_0 = 8 \cdot 854 \times 10^{-12} \text{ C}^2 \text{ N}^{-1} \text{ m}^{-2}$

From Gauss's theorem, electric flux *i.e.* electric lines of force through a surface enclosing a charge q is given by

$$\Phi = \frac{q}{\varepsilon_0}$$

Therefore, electric lines of force originating from a charge of 1 C,

$$\Phi = \frac{1}{8{\cdot}854 \times 10^{-12}} = \mathbf{1 \cdot 129 \times 10^{11}}$$

Problem 4.04. Careful measurement of the electric field at the surface of a black box indicates that the net outward flux through the surface of the box is 8 · 0 × 10^3 N m^2 C^{-1}.

) What is the net charge inside the box ? (*b*) If the net itward flux through the surface of the box were zero, uld you conclude that there were no charges inside the x ? Why or why not ? (*Text Problem*)

Sol. Here, $\Phi = 8 \cdot 0 \times 10^3 \text{ N m}^2 \text{ C}^{-1}$

(*a*) Suppose that the net charge inside the box is q. Then, cording to Gauss's theorem,

$$\Phi = \frac{q}{\varepsilon_0} \quad \text{or} \quad q = \varepsilon_0 \Phi$$

Now, $\varepsilon_0 = 8 \cdot 854 \times 10^{-12} \text{ C}^2 \text{ N}^{-1} \text{ m}^{-2}$

$\therefore$ $q = 8 \cdot 854 \times 10^{-12} \times 8{\cdot}0 \times 10^3$

$= \mathbf{70 \cdot 832 \times 10^{-9}}$ **C**

(*b*) If the net outward flux through the surface of the box zero, it cannot be concluded that there is no charge inside e box. There may be equal amounts of positive and negative arges inside the box. Therefore, if the net outward flux is ro, we cannot conclude that the charge inside the box is ro. One can only say that the net charge inside the box is ro.

Problem 4.05. A point charge + 10 μC is at a distance cm directly above the centre of a square of side 10 cm as own in Fig. 4.13. What is the magnitude of the electric flux rough the square ? (*Text Problem*)

Sol. Here, $q = +10 \ \mu\text{C} = 10^{-5}$ C

Consider that the charge q is at a distance of 5 cm from e square ABCD of each side 10 cm [Fig. 4.13]. The square

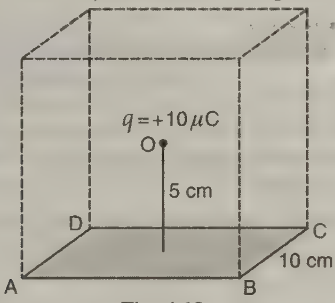

Fig. 4.13

BCD can be considered as one of the six faces of a cube of ch side 10 cm. Then, according to Gauss's theorem, total ectric flux through all the six faces of the cube,

$$\Phi = \frac{q}{\varepsilon_0}$$

Obviously, the flux through the square ABCD will be

$$\phi = \frac{1}{6} \times \Phi = \frac{1}{6} \times \frac{q}{\varepsilon_0}$$

$$= \frac{1}{6} \times \frac{10^{-5}}{8{\cdot}854 \times 10^{-12}}$$

$$= \mathbf{1 \cdot 88 \times 10^5 \text{ N m}^2 \text{ C}^{-1}}$$

pe C. On Calculation of Electric field

Problem 4.06. An infinite line charge produces a field 9 × 10⁴ N C⁻¹ at a distance of 4 cm. Calculate the linear arge density. (*H.S.S.C.E. 2001*)

Sol. Here, $E = 9 \times 10^4 \text{ N C}^{-1}$; $r = 4 \text{ cm} = 0 \cdot 04$ m

Electric field at a distance r from a line charge having ear charge density λ is given by

$$E = \frac{1}{2\pi\varepsilon_0} \cdot \frac{\lambda}{r}$$

$$\therefore \quad \lambda = 2\pi\varepsilon_0 E r = 4\pi\varepsilon_0 \cdot \frac{E r}{2}$$

$$= \frac{1}{9 \times 10^9} \times \frac{9 \times 10^4 \times 0{\cdot}04}{2}$$

$$= \mathbf{2 \times 10^{-7} \text{ C m}^{-1}}$$

Problem 4.07. A large plane sheet of charge having surface charge density $5 \cdot 0 \times 10^{-6}$ C m⁻² lies in the XY-plane. Find the electric flux through a circular area of radius 0 · 1 m, if the normal to the circular area makes an angle of 60° with the Z-axis. Given that $\varepsilon_0 = 8 \cdot 85 \times 10^{-12}$ C² N⁻¹ m⁻².

Sol. The electric flux through a surface,

$$\phi = \vec{E} \cdot \vec{\Delta S} = E \, \Delta S \cos\theta$$

We know that electric field near the plane sheet of charge,

$$E = \frac{\sigma}{2\varepsilon_0}$$

and circular area, $\Delta S = \pi r^2$

$$\therefore \quad \phi = \frac{\sigma}{2\varepsilon_0} \times \pi r^2 \cos\theta$$

Here, $\sigma = 5 \cdot 0 \times 10^{-6} \text{ C m}^{-2}$;

$\varepsilon_0 = 8 \cdot 85 \times 10^{-12} \text{ C}^2 \text{ N}^{-1} \text{ m}^2$; $r = 0 \cdot 1$ m

and $\theta = 60°$

$$\text{Hence, } \phi = \frac{5{\cdot}0 \times 10^{-16} \times \pi \times (0{\cdot}1)^2 \cos 60°}{2 \times 8{\cdot}85 \times 10^{-12}}$$

$$= \mathbf{4 \cdot 44 \times 10^3 \text{ N m}^2 \text{ C}^{-1}}$$

Problem 4.08. Two large thin metal plates are parallel and close to each other as shown in the Fig. 4.14. On their inner faces, the plates have surface charge densities of opposite signs and of magnitude $17 \cdot 0 \times 10^{-22}$ C m⁻². What is E (*a*) to the left of the plates, (*b*) to the right of the plates and (*c*) between the plates ? (*Text Problem*)

Sol. Here, $\sigma = 17 \cdot 0 \times 10^{-22} \text{ C m}^{-2}$

(*a*) ***To the left of plates*** : The region I is to the left of the plates. Therefore, as discussed in section 4.09, the electric field to the left of plates is **zero.**

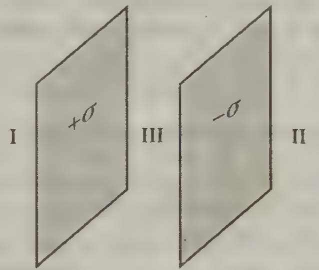

Fig. 4.14

(*b*) ***To the right of plates*** : The region II is to the right of the plates. Again, the electric field in the region II is **zero.**

(*c*) ***Between the two plates*** : In the region III between the two plates, the electric field given by

$$E = \frac{\sigma}{\varepsilon_0} = \frac{17{\cdot}0 \times 10^{-22}}{8{\cdot}854 \times 10^{-12}} = \mathbf{1 \cdot 92 \times 10^{-10} \text{ N C}^{-1}}$$

Problem 4.09. A spherical conductor of radius 12 cm has a charge of $1 \cdot 6 \times 10^{-7}$ C distributed uniformly on its surface. What is the electric field (*a*) inside the sphere (*b*) just outside the sphere (*c*) at a point 18 cm from the centre of the sphere ? (*Text Problem*)

Sol. Here, $q = 1 \cdot 6 \times 10^{-7}$ C ;

radius of the sphere ; R = 12 cm = 0 · 12 cm

(*a*) ***Inside the sphere*** : The charge on a conductor resides on its outer surface. Therefore, electric field inside the sphere is **zero.**

84-0(

(*b*) *Just outside the sphere* : For a point on the charged spherical conductor or outside it, the charge may be assumed to be concentrated at its centre. Therefore,

electric field just outside the sphere

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{R^2} = 9\times10^9\times\frac{1\cdot6\times10^{-7}}{(0\cdot12)^2} = \mathbf{10^5\ N\ C^{-1}}$$

(*c*) *At a point 18 cm from the centre* : Here, $r = 18$ cm

Electric field at a point 18 cm from the centre

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{R^2} = 9\times10^9\times\frac{1\cdot6\times10^{-7}}{(0\cdot18)^2}$$

$$= \mathbf{4\cdot44\times10^4\ N\ C^{-1}}$$

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem. 4.10. A charge q is disturbed uniformly on a ring of radius r. A sphere of equal radius r is centred at the circumference of the ring [Fig. 4.15]. Find the flux of the electric field through the surface of the sphere.

Sol. Let C be the centre of the ring and O be the centre of the sphere. The sphere encloses charge present on the part AOB of the ring.

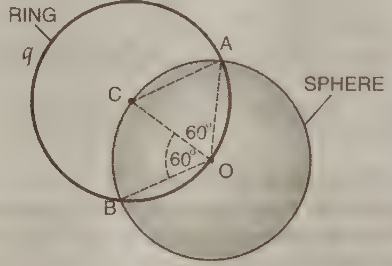

Fig. 4.15

Let us first find the length of part AOB of the ring. It follows that

CA = CO = r (radius of the ring)

and OA = r (radius of the sphere)

Therefore, Δ AOC is an equilaterial triangle and hence ∠ AOC = 60°.

Similarly, it can be proved that ∠ BOC = 60°.

∴ ∠ AOB = ∠ AOC + ∠ BOC = 60° + 60° = 120°

Since the part AOB of the ring subtends an ∠ 120° at the centre of the ring, its one third part is inside the sphere.

Hence, charge enclosed by the sphere, $q' = \frac{q}{3}$

From Gauss's theorem, the flux of the electric field through the surface of the sphere,

$$\phi = \frac{q'}{\varepsilon_0} = \frac{q}{3\varepsilon_0}$$

Problem 4.11. The electric field in a region is radially outward and varies with distance r as

$$\mathbf{E = 250\,r\ V\ m^{-2}}$$

Calculate the charge contained in a sphere of radius 0 · 2 m centred at the origin.

Sol. Here, $E = 250\,r$ V m^{-2} and radius of sphere, $a = 0{\cdot}2$ m

Let $E_{surface}$ be electric field at the surface of the sphere.

Then, $E_{surface} = 250\,a$ V m^2 = 250 × 0 · 2 = 50 V m^{-2}

Electric flux crossing through the sphere,

$$\phi = \oint \vec{E}_{surface}\cdot\vec{dS} = E_{surface}\times4\pi a^2$$

or $\phi = 50\times4\ \pi\times(0\cdot2)^2$ N m^2 C^{-1}

If q is charge contained in the sphere, then according to Gauss's theorem,

$$\phi = \frac{q}{\varepsilon_0}$$

or $q = \varepsilon_0\phi = \varepsilon_0\times50\times4\ \pi\times(0\cdot2)^2$

$$= 4\pi\ \varepsilon_0\times50\times(0\cdot2)^2$$

$$= \frac{1}{9\times10^9}\times50\times(0\cdot2)^2 = \mathbf{2\cdot22\times10^{-10}\ C}$$

Problem 4.12. A spherical conducting shell of inner radius r_1 and outer radius r_2 has a charge Q [Fig. 4.16]. A charge q is placed at the centre of the shell. What is the surface charge density of the inner and outer surfaces of the shell ? (*Text Question*)

Sol. When charge Q is given to the conducting shell, it will appear on its outer surface. When charge q is placed at the centre of the shell, it must induce charge $-q$ on the inner surface and $+q$ on the outer surface of the shell. Otherwise, there will be electric field inside the conducting shell. Thus, there is charge $-q$ on the inner surface and Q + q on the outer surface of the shell.

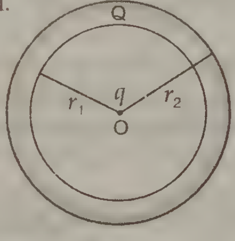

Fig. 4.16

Therefore, charge density of inner surface,

$$\sigma_1 = -\frac{q}{4\pi r_1^2}$$

and charge density of outer surface,

$$\sigma_2 = \frac{Q+q}{4\pi r_2^2}$$

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 4.01. What do you understand by electric flux ? (*P.S.S.C.E. 2001, 2000 ; H.S.S.C.E. 1995*)

Ans. Electric flux is associated with electric field.

The electric flux through a surface held inside an electric field represents the total number of electric lines of force crossing the surface in a direction normal to the surface.

Q. 4.02. Is electric flux a scalar or a vector ? Give the SI unit of electric flux.

Ans. Electric flux is a scalar quantity and its unit is N m^2 C^{-1}.

Q. 4.03. An area S is held inside an electric field E, such that normal to the area S subtends angle θ with the direction

electric field. What is the electric flux linked with the rface area ?

Ans. The electric flux linked with the surface is given by

$$\phi = E\,S\cos\theta$$

Q. 4.04. What is the relation between electric intensity d flux ? *(P.S.S.C.E. 1999, 1998, 1997)*

Ans. If an elementary surface area dS is held inside the ctric field E and E_n is the component of electric field normal he surface area dS, then electric flux through the surface

$$d\phi = E_n\,dS$$

In vector notation, $d\phi = \vec{E}\,.\,\vec{dS}$

Q. 4.05. State Gauss's theorem in electrostatics. *(P.S.S.C.C.E. 2002)*

Ans. Refer to section 4.03.

Q. 4.06. A box encloses an electrical dipole consisting charge 5 μC and – 5 μC and of length 10 cm. What is the al electric flux through the box ?

Ans. Since net charge enclosed by the box is zero, electric x through the box is also zero.

Q. 4.07. What is the use of gaussian surface ?

Ans. For finding electric field due to a charge tribution by apply Gauss's theorem, one is required to aluate a surface integral. The surface integral can be luated easily by choosing a suitable gaussian surface for charge distribution.

Q. 4.08. If Coulomb's law involved $1/r^3$ dependence (instead of $1/r^2$), would Gauss's law be still true ?

Ans. If Coulomb's law involved $1/r^3$ dependence, Gauss's law would not be true.

Q. 4.09. Does the strength of electric field due to an infinitely long line charge depend upon the distance of the observation point from the line charge ?

Ans. Yes, the electric field due to an infinitely long line charge depends upon the distance of the observation point from the line charge.

Q. 4.10. Does the strength of electric field due to an infinite plane sheet of charge depend upon the distance of the observation point from the sheet of charge ?

Ans. No, the electric field due to an infinite plane sheet of charge does not depend upon the distance of the observation point from the plane sheet of charge.

Q. 4.11. What is the difference between a sheet of charge and a plane conductor having charge ?

Ans. On a sheet of charge, the same charge shows up on its two sides ; whereas in case of a charged plane conductor, charges showing up on the two surfaces are not the same.

Q. 4.12. What is the strength of the electric field inside a charged spherical shell ?

Ans. The strength of electric field inside a charged spherical shell is zero.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

Q. 4.01. If the electric field is given by $6\hat{i}+3\hat{j}+4\hat{k}$, culate the electric flux through a surface of area 20 units ng in YZ-plane. *(H.S.S.C.E. 1997 S)*

Ans. Here, $\vec{E} = 6\hat{i}+3\hat{j}+4\hat{k}$

The area vector representing the surface of area 20 units YZ-plane is given by

$$\vec{S} = 20\,\hat{i}$$

Therefore, electric flux through the surface,

$$\phi = \vec{E}\,.\,\vec{S} = (6\hat{i}+3\hat{j}+4\hat{k})\,.\,20\,\hat{i}$$

$$= \mathbf{120\ units}$$

Q. 4.02. What is the importance of Gauss's theorem ?

Ans. Gauss's theorem is of great importance. Those ations, in which calculation of electric field by applying ulomb's law or the principle of superposition of electric ds becomes very difficult, the results can be obtained by plying Gauss's theorem with great ease.

Q. 4.03. What is a gaussian surface ? Explain in brief.

Ans. Refer to section 4.05.

Q. 4.04. Suppose a gaussian surface does not include net charge. Does it necessarily mean that E is equal to o for all points on the surface ? *(Text Question)*

Ans. If a gaussian surface does not include any net rge, there can be electric field on the surface of the gaussian face but parallel to the surface. However, it will require t the source charge should lie outside the gaussian surface.

Q. 4.05. A spherical Gaussian surface encloses a charge 8·85 × 10^{-8} C. (*i*) Calculate the electric flux passing ough the surface, (*ii*) If the radius of the Gaussian surface doubled, how would the flux change ? *(C.B.S.E. 2001)*

Ans. (*i*) Electric flux through the surface,

$$\Phi = \frac{q}{\varepsilon_0} = \frac{8{\cdot}85\times10^{-8}}{8{\cdot}85\times10^{-12}} = \mathbf{10^4\ N\ m^2\ C^{-1}}$$

$$(\because \varepsilon_0 = 8\cdot85\times10^{-12}\ C^2\,N^{-1}\,m^{-2})$$

(*ii*) There will be no effect on electric flux, when the radius of the Gaussian surface is doubled. It is because, the charge enclosed by the Gaussian surface remains the same.

Q. 4.06. A point charge causes an electric flux of $-1\cdot0\times10^3$ N m^2 C^{-1} to pass through a spherical Gaussian surface of 10 · 0 cm radius centred on the charge. (*a*) If the radius of the Gaussian surface were doubled, how much flux would pass through the surface ? (*b*) What is the value of the point charge ? *(Text Question)*

Ans. Here, $\Phi = -1{\cdot}0\times10^3$ N m^2 C^{-1} ;

radius of gaussian surface, r = 10 · 0 cm = 0·1 m

(*a*) If the radius of the gaussian surface is doubled, the electric flux through the new surface will still remain same *i.e.* **$-1\cdot0\times10^3$ N m^2 C^{-1}.**

It is because the same charge is enclosed by the gaussian surface in the two cases.

(*b*) Let q be the charge inside the gaussian surface. Then,

$$\Phi = \frac{q}{\varepsilon_0}$$

$$\text{or}\qquad q = \varepsilon_0\,\phi = 8\cdot854\times10^{-12}\times(-1{\cdot}0\times10^3)$$

$$= \mathbf{-8\cdot854\times10^{9}\ C}$$

Q. 4.07. An electric flux of – 5 × 10^3 N m^2 C^{-1} passes through a spherical Gaussian surface of radius 20 cm due to the charge placed at its centre. (*i*) Calculate the charge enclosed by the Gaussian surface. (*ii*) If the radius of the

Gaussian surface is doubled, how much flux would pass through the surface ? (*C.B.S.E. 1998 S*)

Ans. Proceed as in SAQ 4.06.

Q. 4.08. A uniformly charged conducting sphere of 2·4 m diameter has a surface charge density of 80·0 μC m^{-2}. (*a*) Find the charge on the sphere. (*b*) What is the total electric flux leaving the surface of the sphere ? (*Text Question*)

Ans. Here, $\sigma = 80{\cdot}0\ \mu C\ m^{-2} = 80 \times 10^{-6}\ C\ m^{-2}$;

radius of the charged sphere, $R = \dfrac{2{\cdot}4}{2} = 1{\cdot}2$ m

(*a*) Charge on the sphere $= \sigma \times 4\,\pi R^2$
$= 80 \times 10^{-6} \times 4\,\pi \times (1{\cdot}2)^2 = \mathbf{1 \cdot 45 \times 10^{-3}\ C}$

(*b*) Total electric flux leaving the surface of the sphere,

$$\Phi = \frac{q}{\varepsilon_0} = \frac{1{\cdot}45 \times 10^{-3}}{8{\cdot}854 \times 10^{-12}}$$
$$= \mathbf{1 \cdot 64 \times 10^{8}\ N\ m^2\ C^{-1}}$$

Q. 4.09. Two infinite parallel planes have uniform charge densities ± σ. What is the electric field in (*a*) the region between the planes and (*b*) outside ? In what way does the infinite extension of the planes simplify your derivation ?

Ans. (*a*) In the region between the two infinite parallel planes having uniform charge densities ± σ, the electric field is equal to $\dfrac{\sigma}{\varepsilon_0}$.

(*b*) The electric field is zero in the region outside the plates.

The problem has symmetry due to infinite extension of planes.

Q. 4.10. A and B are two conducting spheres of sam radius, A being solid and B hollow. Both are charged to th same potential. What will be the relation between th charges on the two spheres ? (*C.B.S.E. 2001 S*

Ans. Let Q_A and Q_B be the charges on the solid an hollow conducting spheres respectively and R be the radiu of each sphere. When charge is given to a solid conductin sphere, it appears on the outer surface. However, for th calculation of electric field or potential due to a spher (whether hollow or solid) at a point on or outside th sphere, the charge behaves as if it is concentrated at th centre of the sphere. If V_A and V_B are potentials of the tw spheres, then

$$V_A = \frac{1}{4\pi\varepsilon_0} \cdot \frac{Q_A}{R} \quad \text{and} \quad V_B = \frac{1}{4\pi\varepsilon_0} \cdot \frac{Q_B}{R}$$

Since $V_A = V_B$, it follows that
$$Q_A = Q_B$$

Q. 4.11. What is the principle of electrostatic shielding
(*P.S.S.C.E. 2002, 200*

Ans. The electric field inside a hollow conductor is zer Therefore, if an object located inside a hollow conductor i subjected to electric field, there will be no effect of electric fiel on the object. In other words, the hollow conductor shield the object from external electric field.

This concept is made use of to shield the wires carryin audio signals (low frequency signal) from the external electr fields, such as due to atmospheric electricity or due to electr sparks. If such wires are not shielded, the audio signal wi give rise to a noisy sound on reproduction.

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For **a**mbitious, **b**rilliant & **c**urious Students

Q. 4.01. Is it possible to transfer all the charge from a conductor to another insulated conductor ?

Ans. Yes, it is possible. For this to happen, place the charged conductor inside a hollow conductor so that it touches the inside wall of the hollow conductor. Now, whatsoever charge is given to the charged conductor, it gets immediately transferred to the hollow conductor. It is because of the fact that in case of a charged conductor, the charge resides on its surface.

In fact, it forms the principle of Van de Graaff generator.

Q. 4.02. A conductor A with a cavity as shown in Fig. 4.17 is given a charge Q. Show that the entire charge must appear on the outer surface of the conductor. (*Text Question*)

Ans. Consider the gaussian surface (shown dotted) so as to enclose the cavity but lying wholly inside the conductor A as shown in Fig. 4.17.

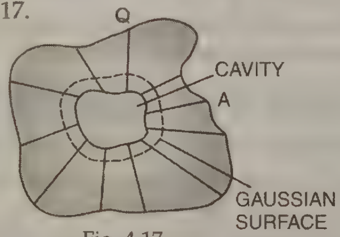

Fig. 4.17

Since the electric field inside a conductor is zero, the part of the conductor within the cavity does not contain any net charge. By extending the same argument, we can say that no charge can be present inside the gaussian surface, which lies just within the conductor.Hence, the entire charge Q mus appear on the outer surface of the conductor A.

Q. 4.03. If in the Q. 4.02, another conductor B wit charge *q* is inserted into the cavity keeping B insulate from A [Fig. 4.18], show that the total charge on the outsid surface of the conductor A is Q + *q*. (*Text Questio*

Ans. Let us again consider the Gaussian surface (show dotted) so that it encloses the cavity and the conductor B wit charge *q* inserted in the cavity [Fig. 4.18].

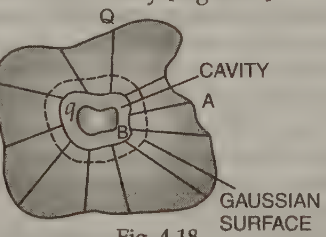

Fig. 4.18

As such, the electric flux will cross the gaussian surfac and it would imply that electric field exists inside th conductor A. But the electric field inside the conductor must be zero. It will be true only if the charge *q* on conduct B induces charge – *q* on the inner surface and + *q* on the oute surface of the conductor A. As there is already a charge + on the outer surface of the conductor A, the total charge o its outer surface becomes Q + *q*.

Q. 4.04. S$_1$ and S$_2$ are two parallel concentric sphere enclosing charges Q and 2 Q respectively as shown i Fig. 4.19.

Vhat is the ratio of the electric flux through S_1 and S_2 ? Iow will the electric flux through the sphere S_1 change, medium of dielectric consant 5 is introduced in the e inside S_1 in place of air ? (C.B.S.E. 2002)

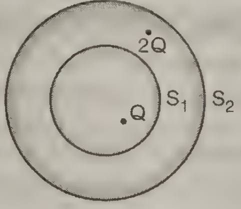

Fig. 4.19

Ans. (*a*) Let Φ_1 and Φ_2 be the electric flux through eres S_1 and S_2 respectively. Then,

$$\Phi_1 = \frac{Q}{\varepsilon_0} \quad \text{and} \quad \Phi_2 = \frac{Q+2Q}{\varepsilon_0} = \frac{3Q}{\varepsilon_0}$$

$$\therefore \quad \frac{\Phi_1}{\Phi_2} = \frac{Q}{\varepsilon_0} \Big/ \frac{3Q}{\varepsilon_0} = \frac{1}{3}$$

(*b*) Let $\vec{E}$ be electric field intensity on the surface of ere S_1 due to charge Q placed inside the sphere. Then, rding to Gauss's theorem,

$$\Phi_1 = \oint \vec{E} \cdot \vec{dS} = \frac{Q}{\varepsilon_0} \qquad ...(i)$$

On introducing medium of dielectric constant K inside the sphere S_1, suppose that electric field on the surface of sphere becomes $\vec{E}'$. Then

$$\vec{E}' = \frac{1}{K}\vec{E} \qquad ...(ii)$$

If the electric flux through the sphere is now Φ_1', then

$$\Phi_1' = \oint \vec{E}' \cdot \vec{dS} = \oint \frac{1}{K}\vec{E} \cdot \vec{dS} = \frac{1}{K}\frac{Q}{\varepsilon_0}$$

[Using equations (*i*) and (*ii*)]

Here, $K = 5$

$$\therefore \quad \Phi_1' = \frac{Q}{5\varepsilon_0}$$

Q. 4.05. A sensitive instrument is to be shielded from the strong electrostatic field in its environment. Suggest a possible way. (*Text Question*)

Ans. The electric field inside a metallic conductor is zero. Therefore, the instrument can be shielded from the strong electrostatic fields by enclosing it with a hollow metallic structure.

Q. 4.06. A man inside an insulated metallic cage does not receive a shock, when the cage is highly charged. Why ?

Ans. It is because, the potential at each point inside the cage is same as that of the cage itself. Since there is no potential difference between the man and the highly charged cage, the man does not receive any shock.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. What is electric flux ? Explain, how the electric flux through a surface is related to electric field intensity, when the surface is held inside the electric field.
2. State Gauss's theorem in electrostatics. How will you prove it for spherically symmetric surfaces ? (*C.B.S.E . 1996, 1995, 1992, 1991 ; H.S.S.C.E. 1992*)
3. State Gauss's theorem. How Coulomb's law can be derived from it ? (*H.P.S.S.C.E. 1999, 1995 ; H.S.S.C.E. 1996 ; P.S.S.C.E. 1995, 1991*)
4. Deduce Coulomb's law from Gauss's theorem in electrostatics. State Gauss's theorem in electrostatics. Use this to find the electric field inside the spherical shell. (*H.P.S.S.C.E. 2002*)
5. State Gauss's theorem in electrostatics. Hence obtain expression for the force between two point charges. (*C.B.S.E. 1991*)
6. Derive, using Gauss's theorem, an expression for the electric field of an infinitely long line of charge having a uniform charge density λ C m^{-1}. (*C.B.S.E. 1990*)
7. State Gauss's theorem in electrostatic and express it mathematically. Using it, derive an expression for electric field intensity at a point near a thin infinite plane sheet of electric charge. (*C.B.S.E. 2001 S*)
8. State Gauss's theorem in electrostatics. Apply this theorem to calculate the electric field due to an infinite plane sheet of charge. (*C.B.S.E. 1995*)
9. State Gauss's theorem in electrostatics. Using it, derive the expression for the electric field at any point due to an infinite plane sheet of charge of uniform charge density σ. (*C.B.S.E. 1996*)
10. State Gauss's theorem. Derive expression for electric field between two infinite plane parallel sheets of charge at a point in the region between the two plates.
11. State Gauss's theorem in electrostatics and express it mathematically. Using the theorem, derive an expression for electric field intensity at a point inside a hollow charged conducting sphere. (*C.B.S.E. 2001 S*)
12. State Gauss's theorem in electrostatics. Prove that no electric field exists inside a hollow charged sphere. (*C.B.S.E. 2002*)
13. Using Gauss's law, show that no electric field intensity exists inside a hollow charged conductor. (*C.B.S.E. 2000*)
14. (*a*) Define the term electric flux. State its units.
    (*b*) A sphere S_1 of radius r_1 encloses a charge Q. If there is another concentric sphere S_2 of the radius r_2 ($r_2 > r_1$) and there be no additional charges between S_1 and S_2, find the ratio of electric flux through S_1 and S_2. (*C.B.S.E. 2001 S*)

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. State and prove Gauss's theorem in electrostatics. Deduce Coulomb's law from Gauss's theorem ? (*H.P.S.S.C.E. 1999 S*)
2. State and prove Gauss's law in electrostatics. Find electric field intensity due to a uniformly charged wire. (*H.S.S.C.E. 1992*)
3. State Gauss's theorem. Give its mathematical expression. Derive an expression for the electric field intensity at any point due to an infinite plane sheet of charge density σ C m^{-2}. (*C.B.S.E. 2001*)
4. State Gauss's law in electrostatics. Apply this law to show that for a spherical shell, the electric field inside the shell

vanishes, whereas outside it, the field is as if all the charge has been concentrated at the centre. (*C.B.S.E. 1992*)

5. Derive expression for the electric field due to a uniformly charged spherical shell at a point (*i*) inside and (*ii*) outside the shell. (*C.B.S.E. 1991*)

6. State Gauss's theorem in electrostatics. Apply this theore to calculate the electric field due to a solid sphere of char at a point (*a*) outside the sphere (*b*) on the sphere and inside the sphere. (*P.S.S.C.E. 1998 S ; C.B.S.E. 199*

FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Electric flux

1. (*a*) A rectangular frame of wire of 25 cm × 15 cm is placed in a uniform electric field of strength 2×10^4 N C^{-1}, such that the plane of the coil is normal to field. Find the electric flux linked with the rectangular frame.
(*b*) Calculate the electric flux linked with the frame, when it is converted into (*i*) a square and (*ii*) a circular frame.
(*c*) In which case is the electric flux maximum ?
[**Ans.** (*a*) 750 N m^2 C^{-1} ; (*b*) (*i*) 800 N m^2 C^{-1} ; (*ii*) 1018·6 N m^2 C^{-1} ; (*c*) circular frame]

2. A plane surface having area of 0·5 m^2 is placed inside a uniform electric field of strength 5×10^3 N C^{-1}. Calculate the electric flux through the surface, when the normal to its plane makes an angle of (*i*) 30°, (*ii*) 60°, (*iii*) 90° with the direction of the electric field.
[**Ans.** (*i*) 2165 · 1 N m^2 C^{-1} ; (*ii*) 1250 N m^2 C^{-1} ; (*iii*) 0]

3. There is uniform electric field of $3 \times 10^3 \, \hat{i}$ N C^{-1}. What is the net flux of the uniform electric field through a cube of side 20 cm oriented so that its faces are parallel to the co-ordinate planes ? [**Ans.** 0]

Type B. On Gauss's theorem

4. A point charge of 10^{-7} coulomb is situated at the centre of a cube of 1 m side. Calculate the electric flux through its surface. (*P.S.S.C.E. 1992 S*) [**Ans.** $1{\cdot}13 \times 10^4$ N m^2 C^{-1}]

5. A point charge of 5 μC is situated at the centre of a sphere of radius 0 · 2 m. Calculate the electric flux through its surface. Given, $\varepsilon_0 = 8 \cdot 854 \times 10^{-12}$ C^2 N^{-1} m^{-2}.
[**Ans.** $5{\cdot}65 \times 10^5$ N m^2 C^{-1}]

6. Find the electric flux through each face of a hollow cube of side 10 cm, if a charge of 8·854 μC is placed at its centre.
[**Ans.** $1{\cdot}67 \times 10^5$ N m^2 C^{-1}]

7. A point charge of 12 μC is located at the centre of a cube of side 1 m. Calculate the electric flux through each face of the cube. (*H.S.S.C.E. 1999 S*) [**Ans.** $2{\cdot}26 \times 10^5$ N m^2 C^{-1}]

8. If the number of electric lines of force emerging out of a closed surface are 10^3, calculate the charge enclosed by the surface. [**Ans.** $8{\cdot}854 \times 10^{-9}$ C]

9. An electric flux of -6×10^3 N m^2 C^{-1} passes through a spherical Gaussian surface of radius 10 cm due to a point charge placed at the centre. (*i*) What is the charge enclosed by the Gaussian surface ? (*ii*) If the radius of the Gussian surface is doubled, how much flux would pass through the surface ? (*C.B.S.E. 1999*)
[**Ans.** (*i*) $-5{\cdot}31 \times 10^{-8}$ C ; (*ii*) unchanged]

Type C. On calculation of Electric field on the basis of Gauss's theorem

10. A charged particle having a charge of -3 μC is placed close to a sheet of charge having a surface charge density 5×10^{-6} C m^{-2}. Find the force of attraction between the particle and the sheet of charge.
[**Ans.** 0·847 N (attractive)]

11. In problem no. 10, if the sheet of charge is replaced by a conducting charged plate, what will be the force of attraction between the particle and the plate.
[**Ans.** 1·694 N (attractiv

12. A particle of mass 9×10^{-5} g is kept over a large horizon sheet of charge having surface charge density 5×10^{-5} C m What charge should be given to this particle so tha released, it does not fall down? [**Ans.** $3{\cdot}12 \times 10^{-13}$

13. In problem no. 12, if the sheet of charge is replaced by conducting charged plate, what charge would be given the particle, so that if released, it does not fall ?
[**Ans.** $1{\cdot}56 \times 10^{-13}$

14. Two large conducting plates are placed parallel to ea other with a separation of 2 cm between them. An electr starting from rest near one of the plates reaches the oth plate in 2 μs. Find the surface charge density of the plat
[**Ans.** $2{\cdot}52 \times 10^{-13}$ C m

15. In problem no. 14, if the two conducting plates are replac by two sheets of charge, what will be the charge density the sheets of charge ? [**Ans.** $5{\cdot}04 \times 10^{-13}$ C m

16. Assume that earth has a charge of surface density electron per metre^2. Calculate the earth's (*i*) electric field electric potential just outside the earth's surface.
[**Ans.** (*i*) $1{\cdot}81 \times 10^{-8}$ N C^{-1} (radially inwwar
(*ii*) – 0·1157

17. The radius of gold nucleus (Z = 79) is about $7{\cdot}0 \times 10^{-15}$ Assuming that the positive charge is distributed uniform throughout the nuclear volume, find the strength of electric field (*a*) at the surface of the nucleus and (*b*) at middle point of the radius.
[**Ans.** (*a*) $2{\cdot}32 \times 10^{21}$ N C^{-1} ; (*b*) $1{\cdot}16 \times 10^{21}$ N C

MICELLANEOUS PROBLEMS

18. A 1 mg ball carrying a charge of 2×10^{-8} C hangs fror thread. When a large conducting plate of charge brought near the ball, the thread makes an angle of with the plate. What is the surface charge density the plate ? [**Ans.** $2{\cdot}505 \times 10^{-9}$ C m

19. If a small sphere of mass m and charge q hangs from a thread at angle θ with a charged conducting plate, sh that for equilibrium of the sphere, the surface cha density for the plate is $\varepsilon_0 \dfrac{mg}{q} \tan\theta$.

20. An electric dipole AB consists of charges ± 5 nC a separated by a distance of 2×10^{-3} m. As shown in F 4.20. The dipole is placed near a long line charge hav linear charge density $4{\cdot}5 \times 10^{-4}$ C m^{-1}, such that negative charge is at a distance OA = 2·5 cm from line charge [Fig. 4.20]. Find the force acting on dipole. [**Ans.** 0·12 N (towards the line char

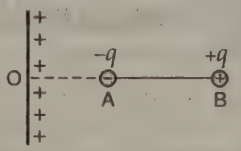

Fig.4.20.

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Here, $A = 25 \times 15 = 375\ \text{cm}^2 = 375 \times 10^{-4}\ \text{m}^2$;
$E = 2 \times 10^4\ \text{N C}^{-1}$

(a) $\phi = EA = 2 \times 10^4 \times 375 \times 10^{-4} = \mathbf{750\ N\ m^2\ C^{-1}}$

(b) (i) *When rectangular frame is converted into a square frame :*

$$\text{One side of the square} = \frac{2(25+15)}{4} = 20\ \text{cm}$$

Area of square, $A_1 = 20 \times 20 = 400\ \text{cm}^2 = 400 \times 10^{-4}\ \text{cm}^2$

Now, $\phi_1 = E A_1 = 2 \times 10^4 \times 400 \times 10^{-4} = \mathbf{800\ N\ m^2\ C^{-1}}$

(ii) When rectangular frame is converted into a circular frame :

$$\text{Radius of circle, } r = \frac{2(25+15)}{2\pi} = \frac{40}{\pi}\ \text{cm}$$

$$\text{Area of circle, } A_2 = \pi r^2 = \pi \left(\frac{40}{\pi}\right)^2$$

$$= 509{\cdot}3\ \text{cm}^2 = 509{\cdot}3 \times 10^{-4}\ \text{m}^2$$

Now, $\phi_2 = E A_2 = 2 \times 10^4 \times 509{\cdot}3 \times 10^{-4} = \mathbf{1018{\cdot}6\ N\ m^2\ C^{-1}}$

(c) Since ϕ_2 is greater than both ϕ and ϕ_1, the electric flux is maximum in case of circular frame.

2. Proceed as in solved problem no. 4.02.

3. Here, $\vec{E} = 3 \times 10^3\ \hat{i}\ \text{N C}^{-1}$;

$A = 20 \times 20 = 400\ \text{cm}^2 = 4 \times 10^{-2}\ \text{m}^2$

Through a face parallel to XY-plane :

$$\vec{A}_1 = 4 \times 10^{-2}\ \hat{k}\ \text{m}^2$$

$$\therefore \quad \phi_1 = \vec{E} \cdot \vec{A}_1 = (3 \times 10^3\ \hat{i}) \cdot (4 \times 10^{-2}\ \hat{k}) = 0$$

Through a face parallel to YZ-plane :

$$\vec{A}_2 = 4 \times 10^{-2}\ \hat{i}\ \text{m}^2$$

$$\therefore \quad \phi_2 = \vec{E} \cdot \vec{A}_2 = (3 \times 10^3\ \hat{i}) \cdot (4 \times 10^{-2}\ \hat{i}) = 120\ \text{N m}^2\ \text{C}^{-1}$$

Through a face parallel to ZX-plane :

$$\vec{A}_3 = 4 \times 10^{-2}\ \hat{j}\ \text{m}^2$$

$$\therefore \quad \phi_3 = \vec{E} \cdot \vec{A}_3 = (3 \times 10^3\ \hat{i}) \cdot (4 \times 10^{-2}\ \hat{j}) = 0$$

In each plane, there is a set of two faces of the cube. Through one face, electric flux enters and through the other face, an equal flux leaves. Therefore, net flux through the cube,

$$\phi = (\phi_1 - \phi_1) + (\phi_2 - \phi_2) + (\phi_3 - \phi_3) = 0$$

4. $$\Phi = \frac{q}{\varepsilon_0} = \frac{10^{-7}}{8{\cdot}854 \times 10^{-12}} = \mathbf{1{\cdot}13 \times 10^4\ N\ m^2\ C^{-1}}$$

5. Proceed as in problem no. 4.

6. Total electric flux through the cube (all the six faces),

$$\Phi = \frac{q}{\varepsilon_0} = \frac{8{\cdot}854 \times 10^{-6}}{8{\cdot}854 \times 10^{-12}} = 10^6\ \text{N m}^2\ \text{C}^{-1}$$

Therefore, electric flux through each face of the cube,

$$\phi = \frac{1}{6}\Phi = \frac{10^6}{6} = \mathbf{1{\cdot}67 \times 10^5\ N\ m^2\ C^{-1}}$$

7. Proceed as in problem no. 5.

8. $q = \varepsilon_0 \Phi = 8{\cdot}854 \times 10^{-12} \times 10^3 = \mathbf{8{\cdot}854 \times 10^{-9}\ C}$

9. *(i)* $q = \varepsilon_0 \Phi = 8{\cdot}854 \times 10^{-12} \times (-6 \times 10^3) = \mathbf{-5{\cdot}31 \times 10^{-8}\ C}$

(ii) There will be **no change** in flux, when radius of Gaussian surface is doubled.

10. $$F = qE = q\left(\frac{\sigma}{2\varepsilon_0}\right) = 3 \times 10^{-6} \times \frac{5 \times 10^{-6}}{2 \times 8{\cdot}854 \times 10^{-12}}$$

$$= \mathbf{0{\cdot}847\ N\ (attractive)}$$

11. $$F = qE = q\left(\frac{\sigma}{\varepsilon_0}\right) = 3 \times 10^{-6} \times \frac{5 \times 10^{-6}}{8{\cdot}854 \times 10^{-12}}$$

$$= \mathbf{1{\cdot}694\ N\ (attractive)}$$

12. Let q be charge given to the particle. As the particle does not fall on being released,

$$qE = mg \quad \text{or} \quad q\left(\frac{\sigma}{2\varepsilon_0}\right) = mg$$

$$\text{or} \quad q = \frac{2\varepsilon_0 mg}{\sigma} = \frac{2 \times 8{\cdot}854 \times 10^{-12} \times 9 \times 10^{-8} \times 9{\cdot}8}{5 \times 10^{-5}}$$

$$= \mathbf{3{\cdot}12 \times 10^{-13}\ C}$$

13. $$\text{Now, } q = \frac{\varepsilon_0 mg}{\sigma} = \frac{8{\cdot}854 \times 10^{-12} \times 9 \times 10^{-8} \times 9{\cdot}8}{5 \times 10^{-5}}$$

$$= \mathbf{1{\cdot}56 \times 10^{-13}\ C}$$

14. Let σ be surface charge density of the conducting plates.

Then, electric field between conducting plates, $E = \dfrac{2\sigma}{\varepsilon_0}$

Force on electron, $F = e \times \dfrac{2\sigma}{\varepsilon_0}$

If m is mass of electron, then acceleration produced,

$$a = \frac{F}{m} = \frac{e}{m} \times \frac{2\sigma}{\varepsilon_0}$$

Since the electron is initially at rest

$$S = 0 \times t + \frac{1}{2} a t^2 = \frac{1}{2} \times \frac{e}{m} \times \frac{2\sigma}{\varepsilon_0} \times t^2$$

$$\text{or} \quad \sigma = \frac{\varepsilon_0 m S}{e t^2}$$

Here, $m = 9{\cdot}1 \times 10^{-31}\ \text{kg}$; $S = 2\ \text{cm} = 0{\cdot}02\ \text{m}$;
$e = 1{\cdot}6 \times 10^{-19}\ \text{C}$ and $t = 2\ \mu s = 2 \times 10^{-6}\ \text{s}$

$$\therefore \quad \sigma = \frac{8{\cdot}854 \times 10^{-12} \times 9{\cdot}1 \times 10^{-31} \times 0{\cdot}02}{1{\cdot}6 \times 10^{-19} \times (2 \times 10^{-6})^2}$$

$$= \mathbf{2{\cdot}52 \times 10^{-13}\ C\ m^{-2}}$$

15. Electric field between two large sheets of charge,

$$E = \frac{\sigma}{\varepsilon_0}$$

Proceeding as in problem no. 14, it can be obtained that

$$\sigma = \frac{2\varepsilon_0 m S}{e t^2} = \frac{2 \times 8{\cdot}854 \times 10^{-12} \times 9{\cdot}1 \times 10^{-31} \times 0{\cdot}02}{1{\cdot}6 \times 10^{-19} \times (2 \times 10^{-6})^2}$$

$$= \mathbf{5{\cdot}04 \times 10^{-13}\ C\ m^{-2}}$$

16. Here, $\sigma = 1$ electron $\text{m}^{-2} = -1{\cdot}6 \times 10^{-19}\ \text{C m}^{-2}$,
radius of earth, $R = 6400\ \text{km} = 6{\cdot}4 \times 10^6\ \text{m}$

Therefore, total charge on earth, $q = 4\pi R^2 \sigma$

(i) Electric field just outside the surface of earth,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{R^2} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{4\pi R^2 \sigma}{R^2} = \frac{\sigma}{\varepsilon_0}$$

$$= -\frac{1{\cdot}6 \times 10^{-19}}{8{\cdot}854 \times 10^{-12}} = -1{\cdot}81 \times 10^{-8}\ \text{N C}^{-1}$$

$$= \mathbf{1{\cdot}81 \times 10^{-8}\ N\ C^{-1}\ (radially\ inward)}$$

(ii) Electric potential just outside the surface of earth,

$$V = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{R} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{4\pi R^2 \sigma}{\varepsilon_0} = \frac{R\sigma}{\varepsilon_0}$$

$$= \frac{6{\cdot}4 \times 10^6 \times (-1{\cdot}6 \times 10^{-19})}{8{\cdot}854 \times 10^{-12}} = \mathbf{-0{\cdot}1157\ V}$$

17. Here, $q = Z e = 79 \times 1{\cdot}6 \times 10^{-19}$ C, $R = 7{\cdot}0 \times 10^{-15}$ m

(*a*) Electric field at the surface of gold nucleus,

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{R^2} = \frac{9\times10^9\times79\times1\cdot6\times10^{-19}}{(7\cdot0\times10^{-15})^2}$$

$$= \mathbf{2{\cdot}32 \times 10^{21}\ N\ C^{-1}}$$

(*b*) Despite the fact that gold is a conductor, it has been assumed that the positive charge is uniformly distributed over the entire nuclear volume. To find electric field at the middle point of the radius, draw a spherical shell of radius R/2 as the Gaussian surface. Therefore,
charge enclosed by Gaussian surface,

$$q' = \frac{4}{3}\pi\left(\frac{R}{2}\right)^3 \times \rho = \frac{4}{3}\pi\left(\frac{R}{2}\right)^3 \times \frac{q}{4/3\times\pi R^3} = \frac{1}{8}q$$

Therefore, electric field at the middle point of the radius

$$E' = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q'}{(R/2)^2} = \frac{1}{4\pi\varepsilon_0}\times\frac{1/8\,q}{(R/2)^2}$$

$$= \frac{1}{2}\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{R^2}\right) = \frac{1}{2}E$$

$$= \frac{1}{2}\times 2{\cdot}32\times10^{21} = \mathbf{1{\cdot}16\times10^{21}\ N\ C^{-1}}$$

18. Here, $m = 1$ mg $= 10^{-6}$ kg ; $q = 2 \times 10^{-8}$ C

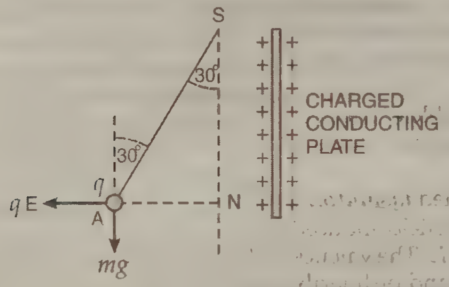

Fig. 4.21

Let σ be charge density of the conducting plate of charge. Then, electric field due to the plate,

$$E = \frac{\sigma}{\varepsilon_0}$$

Force on the charged ball, $F = qE$
Since the charged ball is in equilibrium

$$\frac{qE}{AN} = \frac{mg}{SN} \quad\text{or}\quad \frac{q(\sigma/\varepsilon_0)}{AN} = \frac{mg}{SN}$$

$$\text{or}\quad \sigma = \frac{\varepsilon_0\, mg}{q}\times\frac{AN}{SN} = \frac{\varepsilon_0\, mg}{q}\tan 30°$$

$$= \frac{8\cdot854\times10^{-12}\times10^{-6}\times9\cdot8\times0\cdot5774}{2\times10^{-8}}$$

$$= \mathbf{2{\cdot}505\times10^{-9}\ C\ m^{-2}}$$

19. Proceed as in problem no. 13.

20. Electric field at a distance r from the line charge,

$$E = \frac{1}{2\pi\varepsilon_0}\cdot\frac{\lambda}{r}$$

To calculate force on charge $-q$ at point A :

Here, OA = 2·5 cm = $2{\cdot}5\times10^{-2}$ m

Electric field at point A,

$$E_1 = \frac{1}{2\pi\times8\cdot854\times10^{-12}}\times\frac{4\cdot5\times10^{-4}}{2\cdot5\times10^{-2}}$$

$$= 3{\cdot}24\times10^{8}\ N\ C^{-1}$$

Force on charge $-q$ at point A,

$$F_1 = qE_1 = 5\times10^{-9}\times3{\cdot}24\times10^{8}$$

$= 1{\cdot}62$ N (towards line charg

To calculate force on charge $+q$ at point B :

Here, OB = $2{\cdot}5\times10^{-2} + 2\times10^{-3} = 2{\cdot}7\times10^{-2}$ m

Electric field at point B,

$$E_2 = \frac{1}{2\pi\times8\cdot854\times10^{-12}}\times\frac{4\cdot5\times10^{-4}}{2\cdot7\times10^{-2}}$$

$$= 3{\cdot}0\times10^{8}\ N\ C^{-1}$$

Force on charge $+q$ at point B,

$$F_2 = qE_2 = 5\times10^{-9}\times3{\cdot}0\times10^{-8}$$

$= 1{\cdot}5$ N (away from line charg

Hence, net force on electric dipole,

$$F = F_1 - F_2 = 1{\cdot}62 - 1{\cdot}5$$

$= \mathbf{0{\cdot}12}$ **N (towards line charge)**

Capacitor

5.01. CONDUCTORS, INSULATORS AND DIELECTRICS

The carriers of current in metals are free electrons. The free electron model for ne metal can explain some of the observed properties of the metals in a qualitative nanner.

The elements, in which the valence shell is filled less than half, are found to e good conductors. For example, in metals such as copper, aluminium, silver, etc, ne valence shell contains three or less electrons. Since an atom has a tendency to ave a filled valence shell, the valence electrons in the atoms of a metal leave the toms and are free to move through the metal lattice in a random manner. They onstantly collide among themselves and with the positive ions located in the metal ttice. They have practically no affinity to their parent atoms.

The average velocity of free electrons in a metal is zero. But when an external lectric field is applied across the two ends of a metal, the free electrons experience orce and get accelerated. There is a net flow of electrons through the metal. It is ound that as the strength of the applied electric field is increased, more and more ee electrons cross through a section of the metal. As such, the metals are termed s conductor for electricity.

The materials which do not have free electrons in them are unable to conduct lectricity and are termed as ***insulators***. An insulator may behave in the following vo ways :

1. It may not conduct electricity through it and as such it is called ***insulator***.

2. It may not conduct electricity through it but on applying electric field, induced harges are produced on its faces. Such an insulator is called ***dielectric***. The valence lectrons in atoms of a dielectric are tightly bound to their nuclei and ordinarily annot detach themselves.

Key point

The dielectrics do not conduct electricity. On applying electric field, induced charges of opposite kinds develop on their opposite faces.

5.02. BEHAVIOUR OF A CONDUCTOR IN ELECTROSTATIC FIELD

We know that a conductor possesses free electrons inside it. When a conductor placed inside an electrostatic field, the free electrons in the conductor move in a irection opposite to that of the applied field [Fig. 5.01]. Thus, rearrangement of lectrons takes place. The final distribution of charges at the surface of the conductor such that field set up due to charges on the surface of conductor just cancels the pplied field and hence net field inside the conductor is zero. In case the electric eld had been non-zero inside the conductor, it would lead to flow of current in ne interior of the conductor. Further, the electrostatic field at the surface of the onductor or just outside it cannot have tangential component. Had it been so, it vould lead to the flow of surface current. Thus, when the conductor is placed in ne electric field, the field will be of the form as shown in Fig. 5.02 *i.e.* the electric eld lines will enter or leave the conductor at right angles to the surface of the onductor.

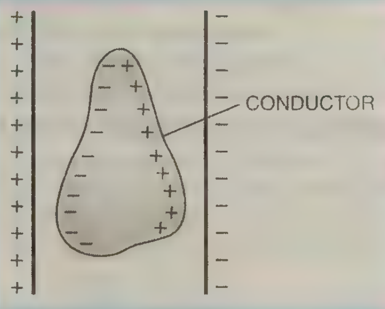

Fig. 5.01

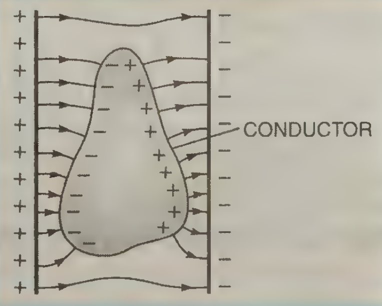

Fig. 5.02

The fact that net electric field inside the conductor is zero implies that there an be no net charge anywhere in the interior of the conductor. It can be proved by sing Gauss's theorem as follows :

Consider a gaussian surface just inside the surface of the conductor. Since there no electric field inside the conductor, the electric flux through the gaussian surface hould be zero. According to Gauss's theorem, the charge inside the gaussian surface iust be zero *i.e.* there is no charge in the interior of the conductor.

Therefore, when a conductor is placed in an electric field, the following onditions apply to it :

1. *Inside the conductor, both the electric field and the charge are zero.*

2. *Charges reside only at the surface of the conductor.*

3. *Immediately outside the surface of the conductor, the electric field is perpendicular to its surface.*

4. *The entire body of the conductor (including its surface) is at constant potential. It is because, electric field inside the conductor can be zero, only if potential inside the conductor is constant.*

5.03. ELECTRICAL CAPACITANCE

Electrical capacitance of a conductor is related to its ability to store the electric charge.

When a conductor is given some electric charge, it is raised to some potential. As more and more charge is given, its potential increases accordingly. If charge q is given to the conductor so that its potential increases by an amount V, then it is found that

$$q \propto V$$

or

$$q = CV \qquad \text{...(5.01)}$$

where the constant of proportionality C is called the *capacitance* of the conductor. Its value depends upon the *shape* and *dimensions* of the conductor. It may be pointed out that the capacitance of a conductor does not depend upon the material of the conductor but depends upon the nature of the medium (its relative permittivity or dielectric constant) in which the conductor is located.

From equation (5.01), we have

$$C = \frac{q}{V}$$

Thus, *capacitance of a conductor may be defined as the ratio of the electric charge on it to its electric potential due to that charge.*

Further, if V=1, then

$$C = q$$

Therefore, *the capacitance of a conductor is numerically equal to the electric charge required to raise its electric potential through one unit.*

In SI, the unit of capacitance is **farad.**

$$\textbf{1 farad (F)} = \frac{\textbf{1 coulomb (C)}}{\textbf{1 volt (V)}} = \textbf{1 coulomb volt}^{-1}(\textbf{C V}^{-1})$$

A conductor is said to have a capacitance of one farad, if 1 coulomb of charge raises its electric potential through 1 volt.

In practice, the following smaller units of capacitance are also used :

1 microfarad (μF) = 10^{-6} farad

1 microfarad ($\mu\mu$F) = 10^{-12} farad

1 $\mu\mu$F is also known as **1 picofarad (pF).**

5.04. CAPACITANCE OF AN ISOLATED SPHERE

Consider an isolated spherical conductor of radius r having charge q. Suppose the conductor is situated in vacuum or air [Fig. 5.03]. The charge on the spherical conductor may be assumed to be present at its centre O. Then, potential at any point on the surface of the conductor is given by

$$V = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r},$$

where $\varepsilon_0 = 8 \cdot 854 \times 10^{-12}\ C^2\ N^{-1}\ m^{-2}$ is absolute permittivity of the free space.

Therefore, capacitance of the isolated spherical conductor situated in vacuum (or air) is given by

$$C = \frac{q}{V} = q \Big/ \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r}$$

or

$$C = 4\pi\varepsilon_0 r \qquad \text{...(5.02)}$$

Hence, the capacitance of an isolated spherical conductor is $4\pi\varepsilon_0$ times its radius. It may be pointed out that in the above expression for capacitance, r is in **metre** and C is in **farad.**

5.05. PRINCIPLE OF A CAPACITOR

A capacitor is a device for storing a large quantity of electric charge.

A conductor can store a small amount of charge and hence it possesses a small capacitance. To store a large amount of charge, two (or more) conductors are arranged to form a capacitor. Thus, a capacitor posseses a large capacitance to store charge and that too in a small space.

Key point

1. When a conductor is charged, charge resides on its outer surface.

2. When a conductor is placed in electric field, the field inside the conductor is zero.

Key point

The capacitance of a conductor depends upon its shape and size. It does not depend upon the nature of the material of the conductor but depends upon the nature of medium in which it is placed.

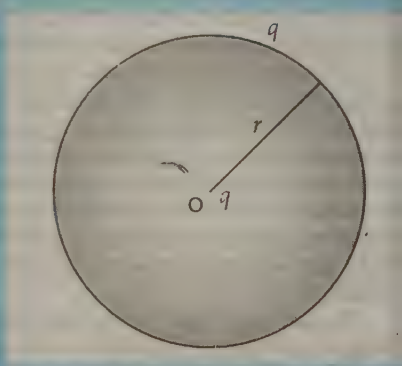

Fig. 5.03

Self-test Question

From equation (5.02), show that units of absolute permittivity are **farad metre^{-1} (F m^{-1}).**

Self-test Question

Using equation (5.02), show that one farad is a huge capacitance.

Principle. To understand the principle of a capacitor, consider an insulated al plate A. Suppose that it is given positive charge, till its potential becomes ximum. The metal plate will not hold any more charge over it. If charge is given he metal plate A, it will leak to the surroundings. Now, place another metallic e B near plate A. Due to induction, negative charge will be induced on the nearer of plate B and positive charge on its farther face as shown in Fig. 5.04. The ential of plate A gets lowered due to induced negative charge on plate B and a raised due to the induced positive charge. Since the metal plates have finite kness, induced negative charge is nearer to the plate A than the induced positive rge on plate B is. Therefore, on the whole, the potential of plate A gets lowered, ugh by a very small amount. In order to make the potential of the metal plate A in the same, an additional small amount of charge has to be given to plate A. It icates that the capacitance of a conductor increases by a small amount, when ther uncharged conductor is placed near it.

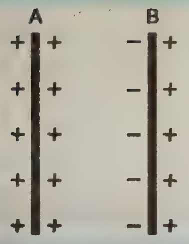

Fig. 5.04

Now, connect the metal plate B to the earth as shown in Fig. 5.05. The induced itive charge on plate B will immediately flow to the earth as it is repelled by itive charge on plate A. However, the induced negative charge on plate B will on it. It does not flow to earth as it is attracted by the positive charge on plate hus, the metal plate B will have only negative charge on it after being connected arth. Due to the induced negative charge on plate B, the potential of A will get ered by a large amount. In order to raise the metal plate A again to the same ential, a large amount of charge has to be given to it. Thus, it follows that the acitance of a conductor is increased greatly, when an earth connected conductor laced near it. It forms the principle of a capacitor and such an arrangement of metal plates is called a **capacitor.**

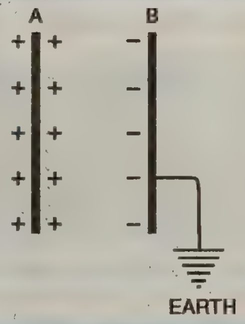

Fig. 5.05

An arrangement of two metallic conductors, so that when one conductor is connected e earth ; the other conductor has the ability to store a large amount of charge on it, is d a capacitor.

The two metallic conductors are called *coatings* of the capacitor. If the coatings spherical, cylindrical or plane ; the capacitor is accordingly called a ***spherical acitor, cylindrical capacitor*** or ***parallel plate capacitor.*** The insulating medium ween the two plates is called *dielectric.* If the insulating medium between the two es is air, it is called air capacitor. If dielectric has dielectric constant K, then acitance of the capacitor becomes K times its capacitance as air capacitor.

5.06. PARALLEL PLATE CAPACITOR

It is most commonly used capacitor. It consists of two conducting plates placed allel to each other [Fig. 5.06]. The separation d between the plates is very small ompared to the area of the plates. Due to small separation between the plates, fringing of electric field at the boundaries is negligible.

If charge $+q$ is given to plate A, then charge $-q$ is induced on the left face of e B and charge $+q$ on its right face. When plate B is earthed, the charge $+q$ on ight face flows to earth. Due to charge $+q$ on plate A and $-q$ on plate B, electric l is set up between the two plates.

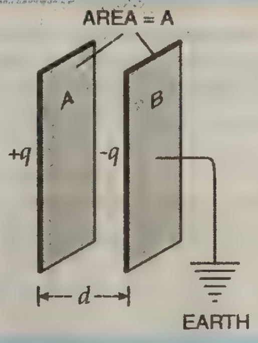

Fig. 5.06

The electric field between the two plates is also given by

$$E = \frac{dV}{dr} \text{ (in magnitude)}$$

Between the two parallel plates, the electric field is uniform* and perpendicular he plates. Therefore, if V is potential difference between the two plates, then

$$E = \frac{V}{d} \qquad \left(\text{For uniform field, } \frac{dV}{dr} = \frac{V}{d}\right)$$

or $$V = E\,d \qquad \text{...(5.03)}$$

Substituting for E in equation (5.03), we have

If σ is surface charge density of the plates, then the two electric field between plates is given by

$$E = \frac{\sigma}{\varepsilon_0},$$

ere ε_0 is absolute permittivity of the free space. (It is assumed that medium ween the plates is vacuum or air).

Key point

In a parallel plate capacitor, the fringing of electric field takes place near the edges of the two plates. In order to minimise the edge effects, the separation between the plates is kept small.

---

* However, near the edges of the plates, the electric field is not uniform. But the *edge effects* become small, if the area of plates is very e as compared to the square of the separation between the plates. To avoid edge effect, the capacitors with *guard rings* are used.

Substituting for E in equation (5.03), we have

$$V = \frac{\sigma}{\varepsilon_0} d$$

Since $\sigma = \frac{q}{A}$, we have

$$V = \frac{q\,d}{\varepsilon_0\,A}$$

If C is the capacitance of the parallel plate capacitor, then

$$C = \frac{q}{V} = \frac{q}{q\,d/\varepsilon_0\,A}$$

or $$C = \frac{\varepsilon_0\,A}{d} \qquad \text{...(5.04)}$$

It gives the capacitance of a parallel plate capacitor, when its plates are held in air or vacuum.

Key point

Electric field between the two plates o parallel plate capacitor is uniform.

Note. 1. If K is dielectric constant of the medium between the two plates, then

$$C = \frac{\varepsilon_0\,K\,A}{d}$$

2. In electrical circuit, a capacitor of fixed capacitance is represented by the symbol as shown in Fig. 5.07 (*a*). In case, if its capacitance is variable, it is represented by the symbol shown in Fig. 5.07 (*b*).

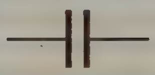

Fig. 5.07 (*a*)

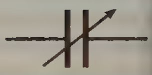

Fig. 5.07(*b*)

5.07. SPHERICAL CAPACITOR

A spherical capacitor consists of two concentric spherical shells, such that one shell is earthed and the other is used to store charge on it. The two spherical shells have a very small spacing between them, which is filled with some dielectric medium, such as wax, paper, etc. As such, a spherical capacitor possesses a very large electrical capacitance.

Expression for capacitance of a spherical capacitor. Fig. 5.08 shows a spherical capacitor consisting of two spherical shells A and B. Let *a* and *b* be their respective radii. The outer spherical shell B is connected to earth. When charge + *q* is given to inner spherical shell A, it induces charge – *q* on the inner surface of the shell B and + *q* on its outer surface. As the shell B is earthed, the charge + *q* on its outer surface flows to earth. If V is potential difference between the spherical shells A and B, then capacitance of the spherical capacitor is given by

$$C = \frac{q}{V}$$

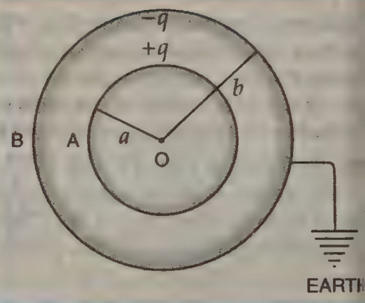

Fig. 5.08

Let us now find the potential difference between the two spherical shells. In case of parallel plate capacitor, the electric field between the two plates was uniform and the potential difference between the two plates was simply equal to E *d*. Here, in the space between the two spherical shells, the electric field is not uniform. It varies with distance and is given by

$$E = \frac{dV}{dr} \qquad \text{(in magnitude)}$$

$$\therefore \quad dV = E\,dr$$

Key point

Electric field between the two coatings a spherical capacitor is not uniform.

The potential difference V between the two spherical shells A and B can be found by integrating both sides between the proper limits. Therefore,

$$V = \int_A^B dV = \int_a^b E\,dr \qquad \text{...(5.05)}$$

To find the value of V, let us find electric field E at any point, say P between the two spherical shells. Let *r* be the distance of point P from the centre O of the spherical shells. Consider the spherical surface of radius *r* (shown dotted) through point P as the gaussian surface [Fig. 5.09]. The gaussian surface encloses the spherical shell A and hence the charge enclosed by the gaussian surface is *q*. According to Gauss's theorem, the total electric flux through the gaussian surface,

$$\Phi = \frac{q}{\varepsilon_0} \qquad \text{...(5.06)}$$

As the magnitude of electric field at every point on the gaussian surface is same, we have

$$\Phi = E \times \text{surface area of gaussian surface}$$

or $$\Phi = E \times 4\pi r^2 \qquad \text{...(5.07)}$$

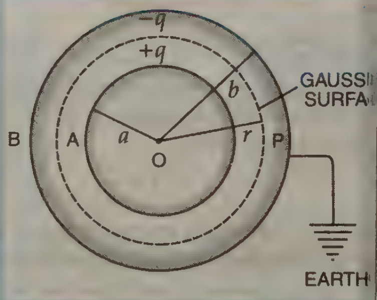

Fig. 5.09

From equations (5.06) and (5.07), we have

$$E \times 4\pi r^2 = \frac{q}{\varepsilon_0}$$

or $$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}$$

Substituting for E in equation (5.05), we have

$$V = \int_a^b \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}\, dr = \frac{q}{4\pi\varepsilon_0} \int_a^b r^{-2}\, dr = \frac{q}{4\pi\varepsilon_0} \left| \frac{r^{-1}}{-1} \right|_a^b = \frac{q}{4\pi\varepsilon_0} \left| -\frac{1}{r} \right|_a^b$$

$$= \frac{q}{4\pi\varepsilon_0} \left| -\frac{1}{b} + \frac{1}{a} \right|_a^b = \frac{q}{4\pi\varepsilon_0} \cdot \frac{b-a}{ab}$$

Therefore, capacitance of the spherical capacitor is given by

$$C = \frac{q}{V} = q \bigg/ \frac{q}{4\pi\varepsilon_0} \cdot \frac{b-a}{ab}$$

or $$C = 4\pi\varepsilon_0 \cdot \frac{ab}{b-a} \qquad ...(5.08)$$

It is the expression for the capacitance of a spherical capacitor.

We know that the capacitance of spherical conductor of radius a is given by

$$C' = 4\pi\varepsilon_0 \cdot a \qquad ...(5.09)$$

Since $\frac{ab}{b-a} > a$, from equations (5.08) and (5.09), it follows that $C > C'$.

Thus, the arrangement of the two spherical shells as explained above leads to crease the capacitance of a spherical conductor.

Key point

The smaller the difference between the radii of the two coatings of a spherical capacitor, greater is its capacitance.

Self-test Question

Show that the capacitance of a spherical capacitor having coating of radii r and R (R > r) is quite large as compared to the capacitance of a conductor of radius R.

5.08. CYLINDRICAL CAPACITOR

A cylindrical capacitor consists of two coaxial cylindrical shells, such that one all is earthed and the other is used to store charge on it. The two cylinderical shells ave a very small spacing between them, which is filled with some dielectric edium.

Expression for capacitance of a cylindrical capacitor. Fig. 5.10 shows a linder capacitor consisting of two cylindrical shells A and B. Let a and b be their spective radii and l be length of the cylindrical shells. When charge + q is given the inner cylindrical shell A, charge equal to – q is induced on the inner surface the cylindrical shell B and charge + q on its outer surface. As the shell B is earthed, e induced charge + q on the outer surface flows to earth.

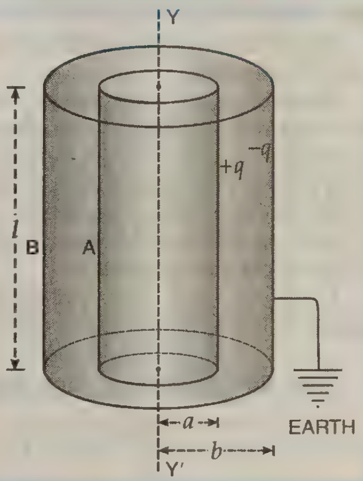

Fig. 5.10

If V is potential difference between the cylindrical shells A and B, then pacitance of the cylindrical capacitor is given by

$$C = \frac{q}{V}$$

As in case of a spherical capacitor, electric field in the space between the two linder shells is also not uniform. Therefore, if electric field at any point P at a stance r from the axis of the cylindrical shells is E, then potential difference between e two shells is given by

$$V = \int_a^b E\, dr \qquad ...(5.10)$$

To find the value of E, draw a cylindrical shell of radius r through point P as e gaussian surface [Fig. 5.11]. It encloses charge q on the inner cylindrical shell A. ccording to Gauss's theorem, the total electric flux through the gaussian surface,

$$\Phi = \frac{q}{\varepsilon_0} \qquad ...(5.11)$$

As the magnitude of electric field at every point on the gaussian surface is same, e have

$$\Phi = E \times \text{surface area of gaussian surface}$$

or $$\Phi = E \times 2\pi r l \qquad ...(5.12)$$

From equations (5.11) and (5.12), we have

$$E \times 2\pi r l = \frac{q}{\varepsilon_0} \quad \text{or} \quad E = \frac{q}{2\pi\varepsilon_0 r l}$$

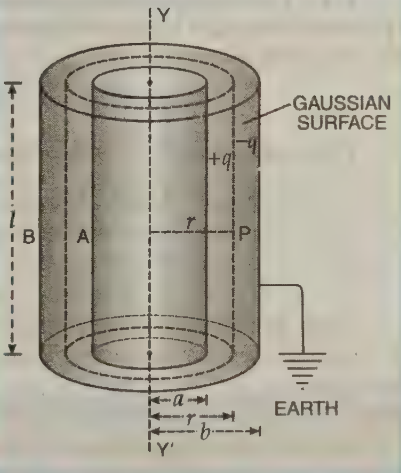

Fig. 5.11

Substituting the value of E in equation (5.10), we have

$$V = \int_a^b E\,dr = \int_a^b \frac{q}{2\pi\varepsilon_0 r l}\,dr = \frac{q}{2\pi\varepsilon_0 l}\int_a^b \frac{1}{r}\,dr = \frac{q}{2\pi\varepsilon_0 l}\Big|\log_e r\Big|_a^b$$

$$= \frac{q}{2\pi\varepsilon_0 l}(\log_e b - \log_e a) = \frac{q}{2\pi\varepsilon_0 l}\log_e\frac{b}{a}$$

Therefore, capacitance of the cylindrical capacitor is given by

$$C = \frac{q}{V} = q \Big/ \frac{q}{2\pi\varepsilon_0 l}\log_e\frac{b}{a}$$

or $$C = \frac{2\pi\varepsilon_0 l}{\log_e\frac{b}{a}} = \frac{2\pi\varepsilon_0 l}{2\cdot 303\log_{10}\frac{b}{a}} \qquad \text{...(5.13)}$$

Also, capacitance of the cylindrical capacitor per unit length is given by

$$C' = \frac{2\pi\varepsilon_0}{\log_e\frac{b}{a}} = \frac{2\pi\varepsilon_0}{2\cdot 303\log_{10}\frac{b}{a}} \qquad \text{...(5.14)}$$

5.09. GROUPING OF CAPACITORS

In practice, the capacitors are grouped in two ways *i.e. in series* and *in parallel.* When the capacitors are connected in series, the net capacitance decreases, while when connected in parallel, the net capacitance increases.

5.10. CAPACITORS IN SERIES

Fig. 5.12 shows the method of connecting three capacitors of capacitances C_1, C_2 and C_3 in series.

When charge $+q$ is given to plate A of the capacitor C_1, it induces charge $-q$ on left face and $+q$ on right face of the plate B. Thus, plate C of the capacitor C_2 also gets charge $+q$ on it. Then, it induces charge $-q$ on left face of plate D and charge $+q$ on plate E of the capacitor C_3.The charge $+q$ on plate E induces charge $-q$ on left face of plate F, while the charge $+q$ induced on its right face flows to earth. Thus, the three capacitors get charged with same amount of charge $+q$, when charge $+q$ is given to the first capacitor.

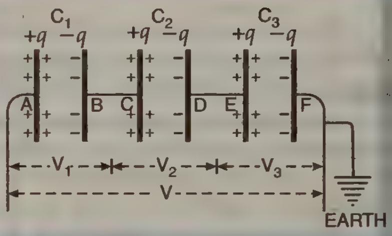

Fig. 5.12

Let V_1, V_2 and V_3 be potential differences across the plates of the three capacitors. If V is the potential difference across the series combination, then

$$V = V_1 + V_2 + V_3$$

From the definition of capacitance,

$$V_1 = \frac{q}{C_1}\ ;\ V_2 = \frac{q}{C_2} \text{ and } V_3 = \frac{q}{C_3}$$

$$\therefore \qquad V = \frac{q}{C_1} + \frac{q}{C_2} + \frac{q}{C_3} = q\left[\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}\right] \qquad \text{...(5.15)}$$

Let C be the equivalent capacitance of the series combination. Therefore, when a potential difference V is applied across a capacitor of capacitance C, it will also sotre the same amount of charge.

Hence, $$V = \frac{q}{C} \qquad \text{...(5.16)}$$

From equations (5.15) and (5.16), we have

$$\frac{q}{C} = q\left(\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}\right)$$

or $$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} \qquad \text{...(5.17)}$$

Thus, *the reciprocal of the resultant (equivalent) capacitance of the series combination of a number of capacitors is equal to the sum of the reciprocals of the capacitances of individual capacitors.*

Key point

In series combination of capacitors,
(*i*) charge on each capacitor is same,
(*ii*) potential difference across a capacitor is inversely proportioal to its capacitance and
(*iii*) the equivalent capacitance is less than the capacitance of the smallest capacitor.

5.11. CAPACITORS IN PARALLEL

Fig. 5.13 shows the method of connecting three capacitors of capacitances C_1, C_2 and C_3 in parallel. One plate of the each capacitor is connected to the source of e.m.f. and the other to the earth. In this manner, all the capacitors are directly

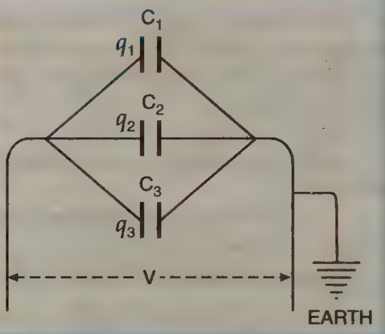

Fig. 5.13

onnected between the source of e.m.f. and the earth and thus possess the same otential difference across their plates. As the capacitors have different capacitances, ey will draw different amounts of charge from the source of e.m.f. If V is potential fference across the parallel combination and q_1, q_2 and q_3 are the values of the arges on the capacitors C_1, C_2 and C_3 respectively, then

$$q_1 = C_1 V; \quad q_2 = C_2 V \quad \text{and} \quad q_3 = C_3 V$$

Total charge on the parallel combination of the capacitors,

$$q = q_1 + q_2 + q_3 = C_1 V + C_2 V + C_3 V$$

or
$$q = (C_1 + C_2 + C_3) V \qquad \text{...(5.18)}$$

If C is the capacitance of the parallel combination, then

$$q = C V \qquad \text{...(5.19)}$$

From equations (5.18) and (5.19), we have

$$C V = (C_1 + C_2 + C_3) V$$

or
$$C = C_1 + C_2 + C_3 \qquad \text{...(5.20)}$$

Thus, *the resultant (equivalent) capacitance of the parallel combination of a number capacitors is equal to the sum of the capacitances of the individual capacitors.*

Key point

In parallel combination of capacitors,
(*i*) potential differene across each capacitor is same,
(*ii*) charge on a capacitor is proportional to its capacitance and
(*iii*) the equivalent capacitance is greater than the capacitance of the largest capacitor.

5.12. ENERGY STORED IN A CHARGED CAPACITOR

If we connect a battery across the two plates of the capacitor, the work is done r energy is supplied) by the battery in charging the capacitor. As the capacitor arges, potential difference across its plates increases. More and more work has be done by the battery in delivering the same amount of charge to the capacitor ue to continuously increasing potential difference across its plates.

The work done in charging a capacitor is stored in the capacitor in the form of electric ergy.

Consider a capacitor of capacitance C. Suppose that the capacitor does not ossess any charge, initially. On being connected to a battery, suppose that it charges a potential V after some time. If q is charge on the plate of the capacitor at that me, then

$$q = C V$$

Suppose battery supplies an infinitesimally small amount of charge dq to the pacitor at constant potential V. Then, according to the definition of potential fference, the small amount of work done by the battery is given by

$$dW = V\, dq = \frac{q}{C}\, dq$$

Therefore, amount of work done in delivering charge q to the capacitor is given

$$W = \int_0^q \frac{q}{C}\, dq = \frac{1}{C}\int_0^q q\, dq = \frac{1}{C}\left|\frac{q^2}{2}\right|_0^q = \frac{1}{2}\frac{q^2}{C}$$

This work done is stored inside the capacitor in the form of the electric potential ergy. Therefore, energy stored in the capacitor,

$$U = \frac{1}{2}\frac{q^2}{C} \qquad \text{...(5.21)}$$

Substituting for q (= C V), equation (5.21) becomes

$$U = \frac{1}{2}\frac{(C V)^2}{C}$$

or
$$U = \frac{1}{2} C V^2 \qquad \text{...(5.22)}$$

Substituting for C $\left(= \frac{q}{V}\right)$, equation (5.22) becomes

$$U = \frac{1}{2}\frac{q}{V} V^2$$

or
$$U = \frac{1}{2} q V \qquad \text{...(5.23)}$$

Therefore, energy stored in a capacitor is given by

$$U = \frac{1}{2}\frac{q^2}{C} = \frac{1}{2} C V^2 = \frac{1}{2} q V$$

Key point

The energy stored in a charged capacitor resides inside it in the form of electric field.

5.13. LOSS OF ENERGY ON SHARING CHARGES BYTWO CAPACITORS

Consider two capacitors having capacitances C_1, C_2 and potentials V_1, V_2 respectively.

Then, the total energy of the two capacitors, before they are connected,

$$U = U_1 + U_2 = \frac{1}{2} C_1 V_1^2 + \frac{1}{2} C_2 V_2^2$$

When the two capacitors are connected together, total charge on the capacitor,

$$q = q_1 + q_2 = C_1 V_1 + C_2 V_2$$

Total capacitance of the two capacitors, $C = C_1 + C_2$

Therefore, total energy of the two capacitors, after they are connected,

$$U' = \frac{1}{2}\frac{q^2}{C} = \frac{1}{2}\frac{(C_1 V_1 + C_2 V_2)^2}{(C_1 + C_2)}$$

Now, $$U - U' = \left(\frac{1}{2} C_1 V_1^2 + \frac{1}{2} C_2 V_2^2\right) - \frac{1}{2}\frac{(C_1 V_1 + C_2 V_2)^2}{(C_1 + C_2)}$$

$$= \frac{C_1^2 V_1^2 + C_1 C_2 V_1^2 + C_1 C_2 V_2^2 + C_2^2 V_2^2 - (C_1 V_1 + C_2 V_2)^2}{2(C_1 + C_2)}$$

$$= \frac{C_1 C_2 (V_1^2 + V_2^2 - 2 V_1 V_2)}{2(C_1 + C_2)} = \frac{C_1 C_2 (V_1 - V_2)^2}{2(C_1 + C_2)}$$

= a positive quantity

Since $U - U'$ is positive, there is always a loss of energy on connecting the two charged capacitors.

Key point

When two charged capacitors are connected to each other, they share charges, till they acquire a common potential. On sharing charges, there is always some loss of energy. However, total charge of the system remains conserved.

5.14. POLAR AND NON-POLAR DIELECTRICS

We know that in an atom, the negative charge in the form of electron cloud is distributed around the nucleus having equal positive charge. As such, in an atom or molecule of a dielectric, the centres of gravity of the positive and negative charges may or may not coincide and likewise the atoms or molecules of the dielectric are termed as ***non-polar*** or ***polar***.

Non-polar dielectric. *A dielectric, in the atoms or molecules of which, the centres of gravity of positive and negative charges coincide, is called a non-polar dielectric.*

Thus, in atoms or molecules of a non-polar dielectric, the positive and negative charges have a symmetrical charge distribution about their centres [Fig. 5.14]. Due to zero separation between the positive and negative charges, the electric dipole moment of such atoms or molecules is zero.

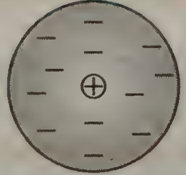

Fig. 5.14

Polar dielectric. *A dielectric, in the atoms or molecules of which, the centres of gravity of positive and negative charges do not coincide, is called a polar dielectric.*

Therefore, in the atoms and molecules of a polar dielectric, the positive and negative charges possess an asymmetrical charge distribution about their centres [Fig. 5.15]. Due to finite separation between the positive and negative charges, such atoms or molecules possess a finite electric dipole moment. The molecules, such as NH_3, HCl, H_2O, CO_2, etc are examples of polar molecules. Water molecule has a permanent dipole moment of the order of 6×10^{-28} C m.

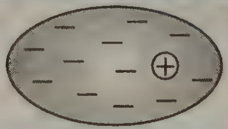

Fig. 5.15

In fact, molecules have normally an asymmetric distribution of charge. For example, in an ionic molecule, the electrons are transferred from one atom to some other atom in the molecule. The resulting molecule is, therefore, made of positive and negative ions in different location and must possess electric dipole moment.

5.15. NON-POLAR ATOM PLACED IN ELECTRIC FIELD (POLARISATION)

When a non-polar atom is subjected to an electric field, the positive nucleus gets pulled along the direction of electric field, while electrons get pulled in the opposite direction [Fig. 5.16]. Due to this, the restoring force is set up so as to bring the electron cloud back to its original state w.r.t. the nucleus. The stretching of atom continues, till the restoring force becomes just equal and opposite to the force exerted by the applied electric field on the charges.

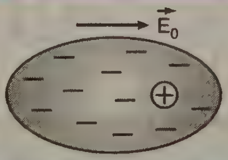

Fig. 5.16

The stretching of dielectric atoms due to displacement of charges in the atoms under the action of the applied electric field is called ***polarisation****.*

As a result of stretching of the atom, centre of gravity of positive nucleus does coincide with that of negative electrons. Due to this, the atom acquires a dipole ment.

5.16. POLARISATION OF A DIELECTRIC SLAB

Consider a parallel plate capacitor having vacuum between the plates. Suppose t the capacitor is charged with a battery so that electric field of strength E_0 is set between the plates [Fig. 5.17]. If σ and $-\sigma$ are surface charge densities of the two tes of the capacitor, then the electric field between two plates is given by

$$E_0 = \frac{\sigma}{\varepsilon_0}$$

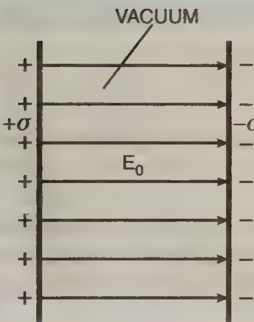

Fig. 5.17

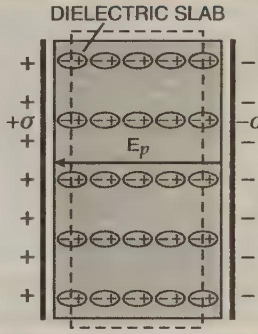

Fig. 5.18

Suppose that a dielectric slab of non-polar atoms is introduced between the two tes of the capacitor [Fig. 5.18]. As soon as the dielectric slab is introduced, each lecule of the dielectric gets polarised *i.e.* centres of gravity of positive and negative rges get displaced from each other. On the left face, a net negative charge $-q_i$ and he right face, a positive charge $+q_i$ appears. There is no net charge in the interior he dielectric marked by the dotted boundary. The charges $-q_i$ and $+q_i$ on the two faces of the dielectric slab are called ***induced charges***. The induced charges set up electric field E_p inside the dielectric. It is called ***electric field due to polarisation***. e direction of electric field due to polarisation is from positive to the negative uced charges developed onthe dielectric slab *i.e.* along a direction opposite to direction of applied electric field E_0. Therefore, the resultant electric field in the lectric is given by

$$E = E_0 - E_p \qquad \text{...(5.24)}$$

In other words, on placing a dielectric slab inside an electric field, the strength he electric field gets reduced and likewise E is called the ***reduced value of the tric field.***

Dielectric constant. *The ratio of the strength of the applied electric field to the strength ne reduced value of the electric field on placing the dielectric between the plates of the acitor is called the dielectric constant of the dielectric medium.*

It is also known as ***relative permittivity*** or ***specific inductive capacity*** and is oted by K (or ε_r). Therefore, dielectric constant of a dielectric medium is given by

$$K = \frac{E_0}{E} \qquad \text{...(5.25)}$$

The value of K is always greater than 1.

Polarisation density. *The induced dipole moment developed per unit volume in a ectric slab on placing it inside the electric field is called polarisation density.* It is denoted P.

If p is induced dipole moment acquired by an atom of the dielectric and N is number of atoms per unit volume, then polarisation density is given by

$$P = N p \qquad \text{...(5.26)}$$

The induced dipole moment acquired by the atom is found to be

$$p = \alpha \, \varepsilon_0 \, E \qquad \text{...(5.27)}$$

Here, constant of proportionality α is called ***atomic polarizability***. For atoms h as hydrogen, lithium, sodium, potassium, etc, the value of α is of the order of ^{29} m^3, while for atoms such as helium, neon, argon, etc, α has a value of the order 0^{-30} m^3. Knowing that $\varepsilon_0 = 8 \cdot 854 \times 10^{-12}$ C^2 N^{-1} m^{-2}, a field of the order of V m^{-1} will produce an induced dipole moment of the order of 10^{-34} C m in case i, Na, K, etc or 10^{-35} C m in case of He, Ne, Ar, etc.

From equations (5.26) and (5.27), we have

$$P = N \alpha \, \varepsilon_0 \, E \qquad \text{...(5.28)}$$

Let A be area of each plate of the capacitor and d, separation between them.

Then, the volume of the dielectric slab = A d

Since induced charges $-q_i$ and $+q_i$ are developed on the two faces of the lectric, the slab possesses total dipole moment equal to $q_i d$. Therefore, from inition of polarisation density,

$$P = \frac{q_i d}{A d} = \frac{q_i}{A}$$

Since $\frac{q_i}{A} = \sigma_p$, polarisation surface charge density, we have

$$P = \sigma_p \qquad \text{...(5.29)}$$

Therefore, on placing dielectric between the two plates of a capacitor, the reduced value of electric field may be expressed as

$$E = \frac{\sigma - \sigma_p}{\varepsilon_0} = \frac{\sigma}{\varepsilon_0} - \frac{\sigma_p}{\varepsilon_0}$$

or $$E = E_0 - \frac{P}{\varepsilon_0} \qquad \text{...(5.30)}$$

Electric susceptibility. The polarisation density of a dielectric slab is directly proportional to the reduced value of the electric field and may be expressed as

$$P = \chi\, \varepsilon_0\, E \qquad \text{...(5.31)}$$

The constant of proportionality χ is called ***electric susceptibility*** of the dielectric slab. It is a dimensionless constant.

Setting the value of P in equation (5.30), we have

$$E = E_0 - \frac{\chi\, \varepsilon_0 E}{\varepsilon_0} = E_0 - \chi E$$

or $$E_0 = E\,(1 + \chi) \qquad \text{...(5.32)}$$

or $$\frac{E_0}{E} = 1 + \chi \qquad \text{...(5.33)}$$

Using equation (5.25), we have

$$K = 1 + \chi \qquad \text{...(5.34)}$$

Also, from equations (5.28) and (5.31), we have

$$\chi\, \varepsilon_0\, E = N \alpha\, \varepsilon_0\, E$$

or $$\chi = N\alpha \qquad \text{...(5.35)}$$

so that $$K = 1 + N\alpha \qquad \text{...(5.36)}$$

5.17. DIELECTRIC STRENGTH

Consider a dielectric slab placed between the parallel plates of a capacitor. As the potential difference across the plates of the capacitor is increased, the strength of applied electric field increases and the molecules of the dielectric undergo more and more stretching. If potential difference is increased gradually, a stage will come, when the electrons break up from the molecules of the dielectric. As a result of this electric break down, the dielectric becomes conducting.

The dielectric strength of a dielectric is defined as the maximum value of electric field (or potential gradient) that can be applied to the dielectric without its electric break down.

The unit of dielectric strength is same as that of electric field **V m^{-1}**. However, the practical unit of dielectric strength is **kV mm^{-1}**.

The table given ahead gives the value of dielectric constants and strengths of some common materials :

Material	Dielectric constant or relative permittivity	Dielectric strength (kV mm^{-1})
Vacuum	1 · 00000	∞
Air	1 · 00054	0 · 8
Water	78	–
Paper	3 · 5	14
Mica	5 · 4	160
Porcelain	6 · 6	4

5.18. CAPACITANCE OF A PARALLEL PLATE CAPACITOR WITH DIELECTRIC SLAB BETWEEN PLATES

Consider a parallel plate capacitor having each plate of area A and separated by a distance d. When there is vacuum between the two plates, the capacitance of the parallel plate capacitor is given by

$$C_0 = \frac{\varepsilon_0 A}{d} \qquad \text{...(5.37)}$$

Suppose that when the capacitor is connected to a battery, electric field of strength E_0 is produced between the two plates of the capacitor. Further, suppose that when dielectric slab of thickness t ($t < d$) is introduced between the two plates of the capacitor [Fig. 5.19], the electric field reduces to E due to polarisation of the dielectric.

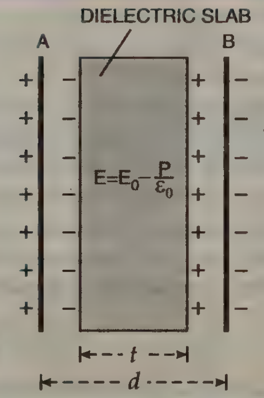

Fig. 5.19

Now, between the two plates of the capacitor ; over a distance t, the strength f electric field is E and over the remaining distance $(d-t)$, the strength of electric eld is E_0. If V is a potential difference between the plates of the capacitor, then

$$V = E\,t + E_0\,(d-t)$$

Since $\frac{E_0}{E} = K$ or $E = \frac{E_0}{K}$, we have

$$V = \frac{E_0}{K}\,t + E_0\,(d-t) = E_0\left(d - t + \frac{t}{K}\right)$$

Now, $E_0 = \frac{\sigma}{\varepsilon_0} = \frac{q}{\varepsilon_0 A}$

∴ $V = \frac{q}{\varepsilon_0 A}\left(d - t + \frac{t}{K}\right)$

Hence, capacitance of a parallel plate capacitor on introduction of dielectric ab is given by

$$C = \frac{q}{V} = q \Big/ \frac{q}{\varepsilon_0 A}\,(d - t + t/K) = \frac{\varepsilon_0 A}{d - t - t/K}$$

or
$$C = \frac{\varepsilon_0 A}{d - t\,(1 - 1/K)} \qquad \text{...(5.38)}$$

If the dielectric slab wholly fills the space between the two plates, then $t = d$. n that case,

$$C = \frac{\varepsilon_0 A}{d - d\,(1 - 1/K)}$$

or
$$C = \frac{\varepsilon_0 K A}{d} \qquad \text{...(5.39)}$$

From equations (5.37) and (5.39), it follows that

$$C = K\,C_0$$

Since $K > 1$, it follows that capacitance of a capacitor increases on introducing dielectric slab between its plates.

Key point

When a dielectric slab is introduced between the plates of a capacitor, its
(*i*) capacitance increases,
(*ii*) potential difference between plates decreases,
(*iii*) charge on the plates remains unchanged and
(*iv*) energy stored in the capacitor decreases.

Key point

When a dielectric slab is introducced between the plates of a capacitor, which is kept connected to a battery, its
(*i*) capacitance increses,
(*ii*) potential difference between the plates remains unchanged,
(*iii*) charge on plates increases and
(*iv*) energy stored in the capacitor increases.

5.19. CAPACITANCE OF A PARALLEL PLATE CAPACITOR WITH CONDUCTING SLAB BETWEEN PLATES

Consider a parallel plate capacitor having each plate of area A and separated y a distance d [Fig. 5.20]. The capacitance of the capacitor is given by

$$C_0 = \frac{\varepsilon_0 A}{d} \qquad \text{...(5.40)}$$

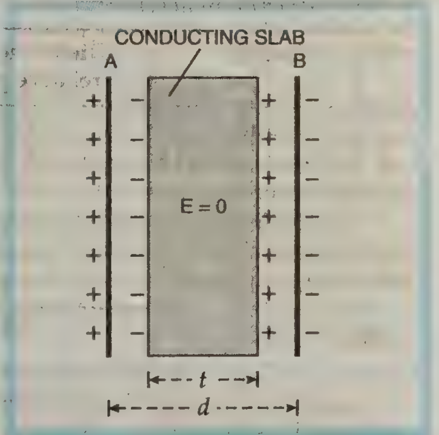

Fig. 5.20

Suppose that when the capacitor is connected to a battery , electric field of rength E_0 is produced between the two plates of the capacitor. Further, suppose that conducting slab of thickness t $(t < d)$ is introduced between the two plates of the apacitor. The electric field inside the conducting slab is zero. Thus, out of the total eparation d between the two plates, the electric field exists only over the distance $l-t)$. As a result, the potential difference will be reduced to

$$V = E_0\,(d-t)$$

or
$$V = \frac{q}{\varepsilon_0 A}\,(d-t) \qquad \left(\because E_0 = \frac{q}{\varepsilon_0 A}\right)$$

Therefore, capacitance of a parallel plate capacitor on introduction of the onducting slab is given by

$$C = \frac{q}{V} = q \Big/ \frac{q}{\varepsilon_0 A}\,(d-t) = \frac{\varepsilon_0 A}{d-t}$$

or
$$C = \frac{\varepsilon_0 A}{d\,(1 - t/d)} \qquad \text{...(5.41)}$$

Using equation (5.40), we have

$$C = \frac{C_0}{(1 - t/d)} \qquad \text{...(5.42)}$$

Thus, on introduction of a conducting slab, the capacitance of a parallel plate apacitor increases.

If the conducting slab wholly fills the space between the two plates, then $t = d$. In that case,

$$C = \frac{C_0}{(1 - d/d)} = \frac{C_0}{0} = \infty$$

i.e. the capacitance of the capacitor will become infinite. In other words, whatsoever amount of charge may be delivered A of the capacitor, it will go on accepting it. The reason is that when the conducting slab wholly fills the space between the two plates, plate A also gets connected to the earth. As such, when charge is delivered to A, it simply flows to the earth through the earth connected plate B. To the observer, it appears as if the capacitance of the capacitor has become infinite.

Self-Test Question

When a conducting slab wholly fills the space between the two plates of a capacitor, its capacitance becomes infinite. Explain, why.

5.20. VAN DE GRAAFF GENERATOR (High Voltage Generator)

In 1931, R. J. Van de Graaff designed an electrostatic generator capable of generating very high potential of the order of 5×10^6 V, which was then made use of in accelerating charged particles so as to carry out nuclear reactions.

Principle. It is based on the following two electrostatic phenomena :

1. The electric discharge takes place in air or gases readily at pointed conductors.
2. If a hollow conductor is in contact with an other conductor, then as charge is supplied to the conductor, the hollow conductor continues accepting the charge irrespective of the fact, howsoever large its potential may grow. The charge immediately shifts to outer surface of the hollow conductor.

Construction and working. Van de Graaff generator consists of a large hollow metallic sphere S mounted on two insulating columns C C′ as shown in Fig. 5.21. An endless belt of an insulating material is made to run on two pulleys P_1 and P_2 with the help of an electric motor. The metal comb C_1, called ***spray comb*** is held near the lower end of the belt. When the spray comb is maintained at high positive potential with the help of E.H.T. source ($\approx 10^4$ V), it produces ions in its vicinity. The positive ions get sprayed on the belt due to the repulsive action of comb C_1, which are carried upward by the moving belt. A comb C_2 called ***collection comb*** is positioned near the upper end of the belt, such that the pointed ends touch the belt and the other end is in contact with the inner surface of the metallic sphere S. The comb C_2 collects the positive ions and transfers them to the metallic sphere. The charge transferred by the comb C_2 immediately moves on to the outer surface of the hollow sphere. As the belt goes on moving, the accumulation of positive charge on the sphere also keeps on taking place continuously and its potential rises considerably. With the increase of charge on the sphere, its leakage due to ionisation of surrounding air also becomes faster. The maximum potential to which the sphere can be raised is reached, when the rate of loss of charge due to leakage becomes equal to the rate at which the charge is transferred to the sphere. To prevent the leakage of charge from the sphere, the generator is completely enclosed inside an earth-connected steel tank, which is filled with air under pressure.

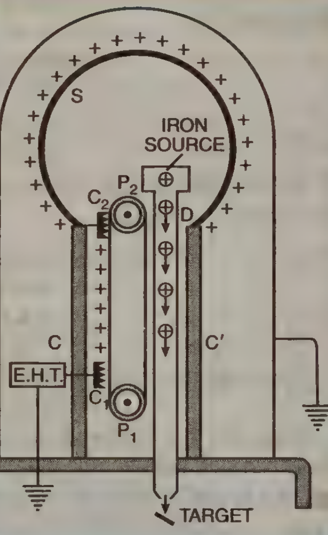

Fig. 5.21

If the projectiles, such as protons, deutrons, etc are now generated in the discharge tube D with lower end earthed and upper end inside the hollow sphere, they get accelerated in downward direction along the length of the tube. At the other end, they come to hit the target with large kinetic energy and bring about nuclear disintegration.

Van de Graaff generator of this type was installed at the Carnegie Institute in Washington in 1937. One such generator was installed at Indian Institute of Technology, Kanpur in 1970 and it accelerates particles to 2 MeV energy.

SOLVED NUMERICAL PROBLEMS

Type A. On Capacitance of a Spherical Conductor

Problem 5.01. Assuming the earth to be a spherical conductor of radius 6400 km, calculate its capacitance. Given,

$$\frac{1}{4\pi\varepsilon_0} = 9 \times 10^9 \text{ N m}^2 \text{ C}^{-2}.$$

(H.P.S.S.C.E. 1998 S ; H.S.S.C.E. 1998 S)

Sol. Here, $r = 6400 \text{ km} = 6 \cdot 4 \times 10^6 \text{ m}$;

$$\frac{1}{4\pi\varepsilon_0} = 9 \times 10^9 \text{ N m}^2 \text{ C}^{-2}$$

In SI, the capacitance of a spherical conductor is given by

$$C = 4\pi\varepsilon_0 r = \frac{1}{9 \times 10^9} \times 6 \cdot 4 \times 10^6$$

$$= 7 \cdot 11 \times 10^{-4} \text{ F} = 711\ \mu\text{F}$$

Problem 5.02. Can a metal sphere of radius 1 cm hold a charge of 1 coulomb ? *(I.I.T. 1975)*

Sol. Here, $r = 1 \text{ cm} = 0{\cdot}01 \text{ m}$; $q = 1$ C

Capacitance of metal sphere,

$$C = 4\pi\varepsilon_0 r = \frac{1}{9 \times 10^9} \times 0 \cdot 01 \text{ F}$$

Therefore, potential of metal sphere, when a charge of is given to it,

$$V = \frac{q}{C} = \frac{1 \times 9 \times 10^9}{0 \cdot 01} = 9 \times 10^{11} \text{ V}$$

Therefore, for metal sphere to hold a charge of 1 C, it l have to be raised to a potential of 9 × 10^{11} V. But even ore such a high potential is reached, the surrounding air omes ionised and the charge leaks to the surroundings. erefore, the given metal sphere **will not be able to hold rge of 1 C.**

Problem 5.03. 27 drops of same size are charged at 220 ach. They coalesce to form a bigger drop. Calculate the ential of the bigger drop. *(P.S.S.C.E 2001)*

Sol. Let r be the radius of each small drop. Then,

capacitance of each small drop, $C = 4\pi\varepsilon_0 r$

Charge on each small drop, $q = CV = 4\pi\varepsilon_0 r \times 220$

Total charge on 27 small drops,

$$Q = 27\,q = 27 \times 4\pi\varepsilon_0 r \times 220$$

When 27 small drops coalesec, let R be the radius of the ger drop formed. Since the volume of the bigger drop must equal to that of 27 small drops,

$$\frac{4}{3}\pi R^3 = 27 \times \frac{4}{3}\pi r^3 \quad \text{or} \quad R = 3r$$

Therefore, capacitance of the bigger drop

$$= 4\pi\varepsilon_0 R = 4\pi\varepsilon_0 \times 3r$$

The charge on bigger drop will be same as that on 27 all drops. Therefore,

$$\text{potential of bigger drop} = \frac{27 \times 4\pi\varepsilon_0 r \times 220}{4\pi\varepsilon_0 \times 3r} = \mathbf{1980\ V}$$

e B. On Capacitance of a parallel plate capacitor

Problem 5.04. What is the area of the plates of a 2 F allel plate capacitor, given that the separation between plates is 0·5 cm ? *(Text Problem ; C.B.S.E. 1990 S)*

Sol. Here, $C = 2$ F ; $d = 0{\cdot}5$ cm $= 0{\cdot}5 \times 10^{-2}$ m

We know, $\varepsilon_0 = 8{\cdot}854 \times 10^{-12}\ \text{C}^2\,\text{N}^{-1}\,\text{m}^{-2}$

$$\text{Now,} \quad C = \frac{\varepsilon_0 A}{d}$$

$$\text{or} \quad A = \frac{Cd}{\varepsilon_0} = \frac{2 \times 0 \cdot 5 \times 10^{-2}}{8 \cdot 854 \times 10^{-12}} = \mathbf{1{\cdot}13 \times 10^9\ m^2}$$

Problem 5.05. A parallel plate capacitor having plate a 100 cm² and plate separation 1 mm holds a charge of 2 μ C, when connected to a 120 V battery. Find the lectric constant of the material between the plates.

Sol. Here, $A = 100\ \text{cm}^2 = 10^{-2}\ \text{m}^2$; $d = 1$ mm $= 10^{-3}$ m ;

$$q = 0{\cdot}12\ \mu\text{C} = 0{\cdot}12 \times 10^{-6}\ \text{C} ; V = 120\ \text{V}$$

Let C be the capacitance of the capacitor. Then

$$C = \frac{q}{V} = \frac{0 \cdot 12 \times 10^{-6}}{120} = 10^{-9}\ \text{F}$$

If K is dielectric constant of the material between the tes, then

$$C = \frac{\varepsilon_0 KA}{d}$$

$$\text{or} \quad K = \frac{Cd}{\varepsilon_0 A} = \frac{10^{-19} \times 10^{-3}}{8 \cdot 854 \times 10^{-12} \times 10^{-2}} = \mathbf{11{\cdot}3}$$

Problem 5.06. Two parallel plate air capacitors have ir plate areas 100 and 500 cm² respectively. If they have the same charge and potential and the distance between the plates of the first capacitor is 0·5 mm, what is the distance between the plates of the second capacitor ? *(P.S.S.C.E. 1997 S)*

Sol. Let A_1 and d_1 be area of plates and distance between the plates of first capacitor ; and A_2 and d_2 be corresponding values in case of the second capacitors. If C_1 and C_2 are the capacitances of the two capacitors, then

$$C_1 = \frac{\varepsilon_0 A_1}{d_1} \quad \text{and} \quad C_2 = \frac{\varepsilon_0 A_2}{d_2}$$

$$\text{We know, } C = \frac{q}{V}$$

Since the two capacitors have same charge and potential, their capacitances must be equal *i.e.* $C_1 = C_2$.

$$\text{or} \quad \frac{\varepsilon_0 A_1}{d_1} = \frac{\varepsilon_0 A_2}{d_2}$$

$$\text{or} \quad d_2 = \frac{A_2}{A_1} d_1$$

Here, $A_1 = 100\ \text{cm}^2$; $A_2 = 500\ \text{cm}^2$

and $d_1 = 0{\cdot}5$ mm $= 0{\cdot}05$ cm

$$\therefore \quad d_2 = \frac{500 \times 0 \cdot 05}{100} = \mathbf{0{\cdot}25\ cm}$$

Type C. On Capacitance of a spherical capacitor

Problem 5.07. The stratosphere acts as a conducting layer for the earth. If the stratosphere extends beyond 50 km from the surface of earth, then calculate the capacitance of the spherical capacitor formed between stratosphere and earth's surface. Take radius of earth as 6400 km.

Sol. We know that the capacitance of a spherical capacitor,

$$C = 4\pi\varepsilon_0 \cdot \frac{ab}{b-a}$$

Here, b = radius of the top of stratosphere layer

$= 6400$ km $+ 50$ km $= 6450$ km $= 6{\cdot}45 \times 10^6$ m

a = radius of earth $= 6400$ km $= 6{\cdot}4 \times 10^6$ m

$$\therefore \quad C = \frac{1}{9 \times 10^9} \times \frac{6 \cdot 45 \times 10^6 \times 6 \cdot 4 \times 10^6}{6 \cdot 45 \times 10^6 - 6 \cdot 4 \times 10^6}$$

$$= \mathbf{0{\cdot}092\ F}$$

Problem 5.08. A spherical capacitor has an inner sphere of radius 12 cm and an outer sphere of radius 13 cm. The outer sphere is earthed and the inner sphere is given a charge of 2·5 μC. The space between the concentric spheres is filled with a liquid of dielectric constant 32. (*a*) Determine the capacitance of the capacitor. (*b*) What is the potential of the inner sphere ? (*c*) Compare the capacitance of this capacitor with that of an isolated sphere of radius 12 cm. *(Text Problem)*

Sol. Here, $a = 12$ cm $= 12 \times 10^{-2}$ m ;

$b = 13$ cm $= 13 \times 10^{-2}$ m

$q = 2{\cdot}5\ \mu\text{C} = 2{\cdot}5 \times 10^{-6}$ C and K = 32

$$(a) \quad C = 4\pi\varepsilon_0 \cdot \frac{Kab}{b-a}$$

$$= \frac{1}{9 \times 10^9} \times \frac{32 \times 12 \times 10^{-2} \times 13 \times 10^{-2}}{13 \times 10^{-2} - 12 \times 10^{-2}}$$

$$= \mathbf{5{\cdot}547 \times 10^{-9}\ F}$$

(*b*) As the outer sphere is earthed, the potential of the inner sphere is equal to the potential difference between the two spheres of the capacitors. Therefore,

$$V = \frac{q}{C} = \frac{2 \cdot 5 \times 10^{-6}}{5 \cdot 547 \times 10^{-9}} = \mathbf{450 \cdot 7\ V}$$

(*c*) Radius of sphere, $r = 12$ cm $= 12 \times 10^{-2}$ m

Now, $$C' = 4\pi\varepsilon_0 r = \frac{1}{9 \times 10^9} \times 12 \times 10^{-2}$$

$$= 1 \cdot 333 \times 10^{-11}\ \text{F}$$

$$\therefore \quad \frac{C}{C'} = \frac{5 \cdot 547 \times 10^{-9}}{1 \cdot 333 \times 10^{11}} \approx \mathbf{416}$$

Type D. On Capacitance of a cylindrical capacitor

Problem 5.09. A cylindrical capacitor has two co-axial cylinders of length 15 cm and radii 1·5 cm and 1·4 cm. The outer cylinder is earthed and the inner cylinder is given a charge of 3·5 μC. Determine the capacitance of the system and the potential of the inner cylinder. Neglect end effects (*i.e.* bending of field lines at the ends). (*Text Problem*)

Sol. Here, $l = 15$ cm $= 15 \times 10^{-2}$ m ;
$a = 1{\cdot}4$ cm $= 1{\cdot}4 \times 10^{-2}$ m ; $b = 1{\cdot}5$ cm $= 1{\cdot}5 \times 10^{-2}$ m ;
$q = 3{\cdot}5\ \mu\text{C} = 3{\cdot}5 \times 10^{-6}$ C

Now, $$C = \frac{2\pi\varepsilon_0 l}{2 \cdot 303 \log_{10}\left(\frac{b}{a}\right)}$$

$$= \frac{2\pi \times 8 \cdot 854 \times 10^{-12} \times 15 \times 10^{-2}}{2 \cdot 303 \log_{10} \frac{1 \cdot 5 \times 10^{-2}}{1 \cdot 4 \times 10^{-2}}}$$

$$= \mathbf{1{\cdot}21 \times 10^{-8}\ F}$$

Since the outer cylinder is earthed, the potential of the inner cylinder will be equal to the potential difference between them.

Therefore, potential of inner cylinder,

$$V = \frac{q}{C} = \frac{3 \cdot 5 \times 10^{-6}}{1 \cdot 21 \times 10^{-10}} = \mathbf{2{\cdot}89 \times 10^4\ V}$$

Type E. On Grouping of capacitors

Problem 5.10. Three capacitors each of capacitance 9 pF are connected in series as shown in Fig. 5.22. (*a*) What is the total capacitance of the combination ? (*b*) What is the potential difference across each capacitor, if the combination is connected to a 120 volt supply ?

(*Text Problem*)

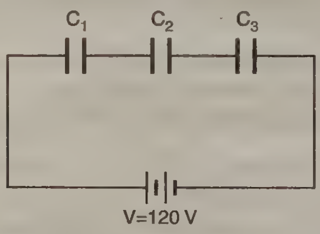

Fig. 5.22

Sol. Here, $C_1 = C_2 = C_3 = 9$ pF $= 9 \times 10^{-12}$ F ; V = 120 volt

(*a*) Total capacitance of the series combination is give
by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} = 3 \times \frac{1}{9 \times 10^{-12}} = \frac{1}{3 \times 10^{-12}}$$

$$\therefore \quad C = 3 \times 10^{-12}\ \text{F} = \mathbf{3\ pF}$$

(*b*) Let q be charge on each capacitor. Then, sum of th
potential differences across the plates of three capacitors mus
be equal to 120 V *i.e.*

$$V_1 + V_2 + V_3 = 120$$

$$\text{or} \quad \frac{q}{C_1} + \frac{q}{C_2} + \frac{q}{C_3} = 120$$

$$\text{or} \quad \frac{q}{9 \times 10^{-12}} + \frac{q}{9 \times 10^{-12}} + \frac{q}{9 \times 10^{-12}} = 120$$

$$\text{or} \quad \frac{3q}{9 \times 10^{-12}} = 120$$

$$\text{or} \quad q = 360 \times 10^{-12}\ \text{C}$$

Therefore, potential difference across a capacitor

$$= \frac{q}{\text{capacitance}} = \frac{360 \times 10^{-12}}{9 \times 10^{-12}}\ \text{s} = \mathbf{40\ V}$$

Alternative method. Since the three capacitors are of th
same capacitances,

potential difference across each capacitor $= \frac{120}{3} = \mathbf{40}$

**Problem. 5.11. Three capacitors of capacitances 2 p
3 pF and 4 pF are connected in parallel as shown in Fig 5.2
(*a*) What is the total capacitance of the combination ? (
Determine the charge on each capacitor, if the combinatio
is connected to a 100 V supply.** (*Text Problem*

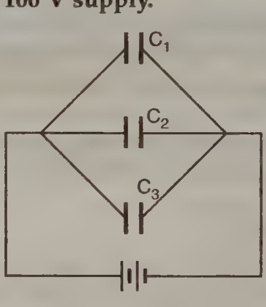

Fig. 5.23

Ans. Here, $C_1 = 2$ pF ; $C_2 = 3$ pF ; $C_3 = 4$ pF ;
V = 100 volt

(*a*) Total capacitance of the parallel combination is give
by

$$C = C_1 + C_2 = C_3 = 2 + 3 + 4 = \mathbf{9\ pF}$$

(*b*) Let q_1, q_2 and q_3 be the charges on C_1, C_2 and C
respectively. In the parallel combination, the potentia
difference across each capacitor will be equal to the suppl
voltage *i.e.* 100 V.

$$\therefore \quad q_1 = C_1 V = 2 \times 10^{-12} \times 100 = \mathbf{2 \times 10^{-10}\ C},$$

$$q_2 = C_2 V = 3 \times 10^{-12} \times 100 = \mathbf{3 \times 10^{-10}\ C}$$

$$q_3 = C_3 V = 4 \times 10^{-12} \times 100 = \mathbf{4 \times 10^{-12}\ C}$$

**Problem. 5.12. Three capacitors of capacitances 5, 4 an
3 μF respectively are connected with the first and secon
in series and the third in parallel with them. Find th
capacitance of the combination.** (*Karnataka, 1983*

Ans. Here, $C_1 = 5\ \mu$F ; $C_2 = 4\ \mu$F ; $C_3 = 3\ \mu$F

The three capacitors have been connected as shown in . 5.24.

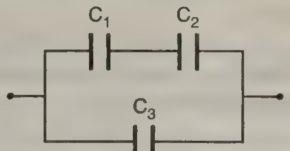

Fig. 5.24

Let C′ be capacitance of the series combination of C_1 and Then,

$$\frac{1}{C'}=\frac{1}{C_1}+\frac{1}{C_2}=\frac{1}{5}+\frac{1}{4}=\frac{4+5}{20}=\frac{9}{20}\quad\text{or}\quad C'=2{\cdot}22\,\mu\text{F}$$

The series combination of C_1 and C_2 have been put in rallel with C_3.

If C is the effective capacitance of the arrangement, then

$$C = C' + C_3 = 2{\cdot}22 + 3 = \mathbf{5{\cdot}22\ \mu F}$$

Problem 5.13. The effective capacitances of two pacitors are 3 μF and 16 μF, when they are connected in ies and parallel respectively. Compute the capacitance each capacitor. *(Karnataka, 1991 S)*

Sol. Let C_1 and C_2 be capacitances of the two capacitors.

Here, $C_s = 3\ \mu F$; $C_p = 16\ \mu F$

The effective capacitance in parallel, $C_p = C_1 + C_2$

$$\therefore \qquad C_1 + C_2 = 16 \qquad \text{...}(i)$$

The effective capacitance in series is given by

$$\frac{1}{C_s}=\frac{1}{C_1}+\frac{1}{C_2}\quad\text{or}\quad C_s=\frac{C_1C_2}{C_1+C_2}$$

$$\therefore \qquad \frac{C_1C_2}{C_1+C_2}=3\quad\text{or}\quad\frac{C_1C_2}{16}=3$$

$$\text{or} \qquad C_1C_2 = 48$$

Now, $(C_1-C_2)^2 = (C_1+C_2)^2 - 4C_1C_2$

$$= (16)^2 - 4\times 48 = 256 - 192 = 64$$

$$\text{or} \qquad C_1 - C_2 = 8 \qquad \text{...}(ii)$$

Adding the equations (*i*) and (*ii*), we have

$$(C_1+C_2)+(C_1-C_2) = 16+8$$

$$\text{or} \qquad \mathbf{C_1 = 12\ \mu F}$$

From equation (*i*), it follows that

$$C_2 = 16 - C_1 = 16 - 12 = \mathbf{4\ \mu F}$$

Problem 5.14. Find the resultant capacitance of the pacitor connected as shown in the Fig. 5.25. *(H.P.S.S.C.E. 1997)*

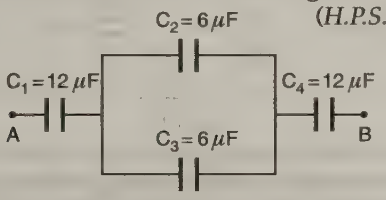

Fig. 5.25

Sol. Let C_{23} be the equivalent capacitance of the pacitors C_2 and C_3 connected in parallel. Then,

$$C_{23} = C_2 + C_3 = 6 + 6 = 12\ \mu F$$

The given network will be equivalent to series angement of the capacitors as shown below in Fig. 5.26.

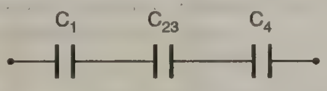

Fig. 5.26

If C is the equivalent capacitance of the series com-
ation, then

$$\frac{1}{C}=\frac{1}{C_1}+\frac{1}{C_{23}}+\frac{1}{C_4}=\frac{1}{12}+\frac{1}{12}+\frac{1}{12}=\frac{1}{4}$$

$$\text{or} \qquad C = 4\ \mu F$$

Problem 5.15. If C_1 = 3 pF and C_2 = 2 pF, calculate the equivalent capacitance of the network shown in Fig. 5.27 between points A and B ? *(C.B.S.E. Sample Q. Paper)*

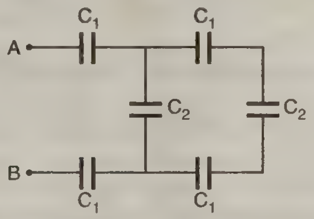

Fig. 5.27

Sol. The given network shown in Fig. 5.27 is equivalent to the arrangement shown in Fig. 5.28, which is further equivalent to arrangement shown in Fig. 5.29.

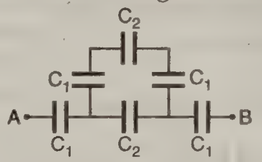

Fig. 5.28

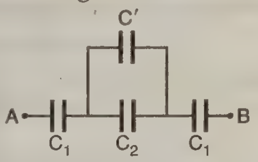

Fig. 5.29

Here, C′ is capacitance of the series combination of C_1, C_2 and C_1. Therefore,

$$\frac{1}{C'}=\frac{1}{C_1}+\frac{1}{C_2}+\frac{1}{C_1}=\frac{1}{3}+\frac{1}{2}+\frac{1}{3}=\frac{7}{6}\quad\text{or } C'=\frac{6}{7}\text{ pF}$$

The arrangement shown in Fig. 5.29 is equivalent to the network drawn in Fig. 5.30.

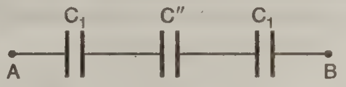

Fig. 5.30

Here, C″ is capacitance of the parallel combination of C′ and C_2. Therefore,

$$C'' = C' + C_2 = \frac{6}{7}+2=\frac{20}{7}\text{pF}$$

If C_{equi} is capacitance of the series combination of C_1, C″ and C_1, then

$$\frac{1}{C_{equi}}=\frac{1}{C_1}+\frac{1}{C''}+\frac{1}{C_1}=\frac{1}{3}+\frac{7}{20}+\frac{1}{3}=\frac{61}{60}$$

$$\text{or} \qquad C_{equi}=\frac{60}{61}\approx \mathbf{1\ pF}$$

Problem 5.16. Five capacitors of capacitances $C_1 = C_5$ = 1 μF , $C_2 = C_3 = C_4$ = 2 μF are connected as shown in Fig. 5.31. Find the equivalent capacitance of the system between points X and Y.

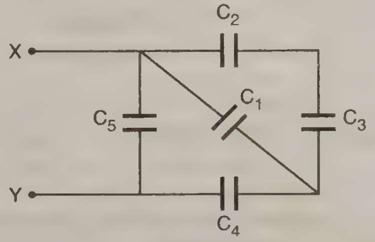

Fig. 5.31

Ans. The capacitors C_2 and C_3 are in series. Their effective capacitance,

$$C_{23} = \frac{C_2 \times C_3}{C_2 + C_3} = \frac{2 \times 2}{2 + 2} = 1\ \mu F$$

The given arrangement of capacitor is equivalent to the arrangement as shown in Fig. 5.32.

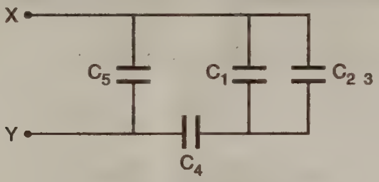

Fig. 5.32

Now, capacitors C_1 and C_{23} are in parallel. Let C_{123} be their effective capacitance. Then,

$$C_{123} = C_1 + C_{23} = 1 + 1 = 2\ \mu F$$

The arrangement of capacitors shown in Fig. 5.32 is now equivalent to the arrangement shown in Fig. 5.33.

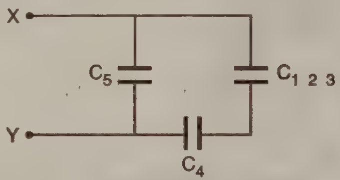

Fig. 5.33

Since the capacitors C_{123} and C_4 are in series, their equivalent capacitance is given by

$$C_{1234} = \frac{C_{123} \times C_4}{C_{123} + C_4} = \frac{2 \times 2}{2 + 2} = 1\ \mu F$$

The arrangement of capacitors shown in Fig. 5.33 is equivalent to the arrangement shown in Fig. 5.34.

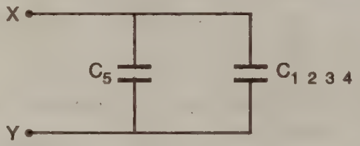

Fig. 5.34

Since capacitors C_{123} and C_5 are in parallel, the equivalent capacitance between points X and Y is given by

$$C = C_{1234} + C_5 = 1 + 1 = 2\ \mu F$$

Problem 5.17. Find the equivalent capacitance of the combination of capacitors between the points A and B as shown in Fig. 5.35. Also calculate the total charge that flows in the circuit, when a 100 V battery is connected between the points A and B. (*C.B.S.E. 2002*)

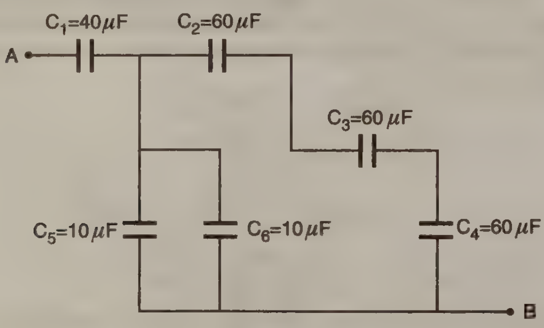

Fig. 5.35

Ans. Refer to the arrangement of capacitors shown i Fig. 5.35. The capacitors C_5 and C_6 are in parallel. Thei effective capacitance,

$$C_{56} = C_5 + C_6 = 10 + 10 = 20\ \mu F$$

Also, capacitors C_2, C_3 and C_4 are in series, so that thei effective capacitance is given by

$$\frac{1}{C_{234}} = \frac{1}{C_2} + \frac{1}{C_3} + \frac{1}{C_4} = \frac{1}{60} + \frac{1}{60} + \frac{1}{60} = \frac{1}{20}$$

or $\quad C_{234} = 20\ \mu F$

The given arrangement of capacitance is equivalent t the arrangement as shown in Fig. 5.36.

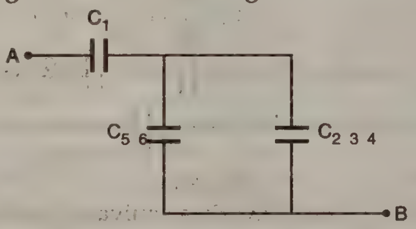

Fig. 5.36

Now, capacitors C_{56} and C_{234} are in parallel. Let C′ b their effective capacitance. Then,

$$C' = C_{56} + C_{234} = 20 + 20 = 40\ \mu F$$

The arrangement of capacitors shown in Fig. 5.36 is no equivalent to the arrangement shown in Fig. 5.37.

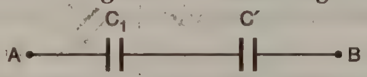

Fig. 5.37

Since the capacitors C_1 and C′ are in series, th equivalent capacitance of the combination between points and B is given by

$$C = \frac{C_1\, C'}{C_1 + C'} = \frac{40 \times 40}{40 + 40} = 20\ \mu F$$

Therefore, total charge that flows in the circuit, when 100 V battery is connected between points A and B is given b

$$q = CV = 20 \times 10^{-6} \times 100 = 2 \times 10^{-3}\ C$$

Problem 5.18. Find the capacitance of the infinit ladder between points X and Y [Fig. 5.38].

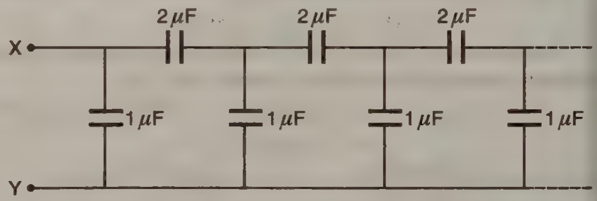

Fig. 5.38

Ans. Let the equivalent capacitance of the entire ladde be C. Since the ladder is infinitely long, adding one more s of two capacitors (1μF and 2μF) across the points X and Y wi not affect the total capacitance *i.e.* it should still remain equ to C. The ladder (whose equivalent capacitance is C) on addin such two capacitors will appear as shown in Fig. 5.39.

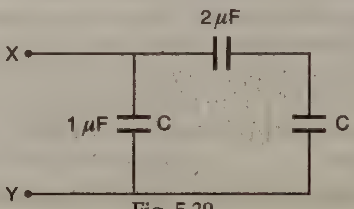

Fig. 5.39

The equivalent capacitance of the arrangement shown bove should again be equal to C *i.e.*

$$C = 1 + \frac{2\times C}{2+C} \quad \text{or} \quad C^2 - C - 2 = 0$$

$$C = 4\,\mu F \quad \text{or} \quad -1\,\mu F$$

Since capacitance can not be negative, the equivalent apacitance of the ladder is **4 μF.**

Problem 5.19. Find the effective capacitance between he terminals X and Y of the network shown in Fig. 5.40. iven that $C_1 = 5\ \mu F$, $C_2 = 10\ \mu F$, $C_3 = 2\ \mu F$, $C_4 = 4\ \mu F$ and $_5 = 10\ \mu F$.

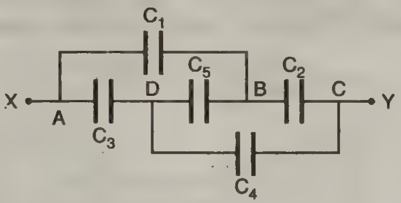

Fig. 5.40

Sol. The given network is equivalent to the network hown in Fig. 5.41.

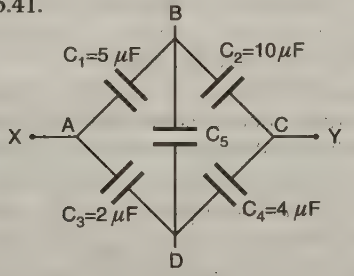

Fig. 5.41

We find that $\frac{C_1}{C_2} = \frac{C_3}{C_4}$

Therefore, the bridge is balanced and hence when some otential difference is applied across terminals X and Y, no urrent will flow across the path BD. Thus, the path BD ehaves as open path and the given network is equivalent to he network as shown in Fig. 5.42.

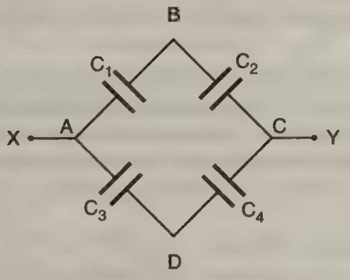

Fig. 5.42

Let C_{12} and C_{34} be capacitances of the series combination f C_1, C_2 and C_3, C_4 respectively.

Then, $\frac{1}{C_{12}} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{5} + \frac{1}{10} = \frac{3}{10}$ or $C_{12} = \frac{10}{3}\ \mu F$

Also, $\frac{1}{C_{34}} = \frac{1}{C_3} + \frac{1}{C_4} = \frac{1}{2} + \frac{1}{4} = \frac{3}{4}$ or $C_{34} = \frac{4}{3}\ \mu F$

Now, C_{12} and C_{34} form a parallel combination. If C is net apacitance of the network, then

$$C = C_{12} + C_{34} = \frac{10}{3} + \frac{4}{3} = \frac{14}{3} = \mathbf{4{\cdot}67\ \mu F}$$

Problem 5.20. An electrical technician requires a capacitance of 2 μF in a circuit across a potential difference of 1 kV. A large number of 1 μF capacitors are available to him, each of which can withstand a potential difference of not more than 400 V. Suggest a possible arrangement that requires a minimum number of capacitors. (*Text Problem*)

Sol. Suppose that the technician makes use of N capacitors and connects them in *m* rows, each row having *n* capacitors. Then, $N = m\,n$

Capacitance of each capacitor = 1 μF ;
required capacitance of the combination, C = 2 μF
voltage rating of each capacitor = 400 V ;
required voltage rating of the combination = 10^3 V

When capacitors are connected in series, potential differences across their plates get added. Therefore, *n* capacitors connected in a row will stand a voltage equal to 400 × *n* V.

Therefore, number of capacitors to be connected in a row is given by

$$400\,n = 10^3$$

$$\text{or} \quad n = \frac{10^3}{400} = 2{\cdot}5 \quad \text{or} \quad n = 3$$

(It can not be a fraction*)

The total capacitance of the capacitors in a row is given by

$$\frac{1}{C'} = \frac{1}{1} + \frac{1}{1} + \frac{1}{1} = 3 \quad \text{or} \quad C' = \frac{1}{3}\ \mu F$$

The total capacitance of *m* rows is given by

$$C = m\,C' \quad \text{or} \quad m = \frac{C}{C'} = \frac{2}{1/3} = 6$$

Therefore, he should make ***three rows of such capacitors, each row containing six capacitors.***

Problem 5.21. Two capacitors C_1 and C_2 are connected to a battery of 6 V as shown in Fig. 5.43. Find the charge on each capacitor.

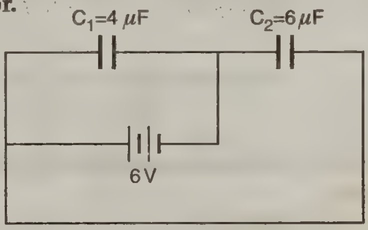

Fig. 5.43

Ans. The given arrangement of two capacitors connected to a battery is equivalent to the arrangement shown in Fig. 5.44

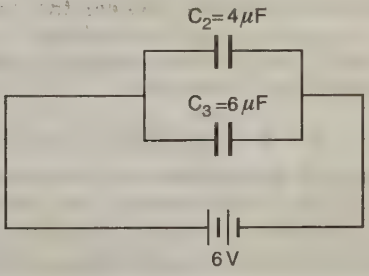

Fig. 5.44

Therefore, charge on capacitor C_1,

$$q_1 = C_1\,V = 4 \times 6 = \mathbf{24\ \mu C}$$

and charge on capacitor C_2,

$$q_2 = C_2\,V = 6 \times 6 = \mathbf{36\ \mu C}$$

---

*n cannot be equal to 2. Otherwise, potential difference across a capacitor will be 500 V *i.e.* more than its voltage rating.

Problem 5.22. Three capacitors C_1, C_2 and C_3 are connected to a battery of 6 V as shown in Fig. 5.45. Find the charges on the three capacitors.

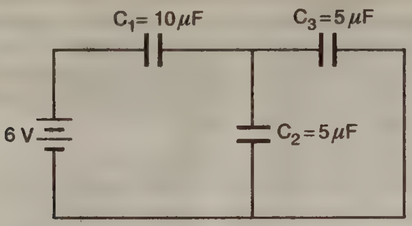

Fig. 5.45

Sol. The given arrangement of three capacitors connected to a battery is equivalent to the arrangement shown in Fig. 5.46.

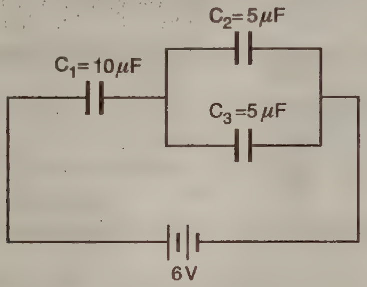

Fig. 5.46

Since capacitors C_2 and C_3 are in parallel, their equivalent capacitance,

$$C_{23} = 5 + 5 = 10\ \mu F$$

The arrangement of capacitors shown in Fig. 5.46 is now equivalent to the network shown in Fig. 5.47.

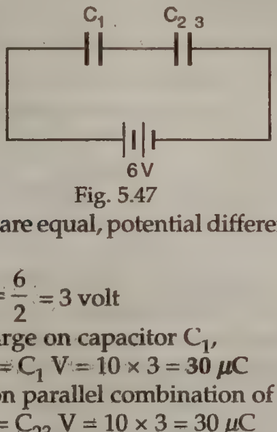

Fig. 5.47

As C_1 and C_{23} are equal, potential difference across each of them will be

$$V = \frac{6}{2} = 3 \text{ volt}$$

Therefore, charge on capacitor C_1,

$$q_1 = C_1 V = 10 \times 3 = 30\ \mu C$$

Also, charge on parallel combination of C_2 and C_3,

$$q_{23} = C_{23} V = 10 \times 3 = 30\ \mu C$$

As C_2 and C_3 are equal, the charge q_{23} is shared equally by the two capacitors. Therefore,

$$q_2 = q_3 = \frac{30}{2} = 15\ \mu C$$

Problem 5.23. A capacitor of 4 μF is connected to 400 V supply. It is then disconnected and connected to an uncharged capacitor of 2 μF. Calculate the common potential after the capacitors are connected together.

(Pre-degree Kerala, 1992)

Sol. Here, $C_1 = 4\ \mu F = 4 \times 10^{-6}$ F ; $V_1 = 400$ V ;

$$C_2 = 2\ \mu F = 2 \times 10^{-6}\ F$$

Therefore, charge on capacitor C_1,

$$q_1 = C_1 V_1 = 4 \times 10^{-6} \times 400 = 1{\cdot}6 \times 10^{-3}\ C$$

Charge on capacitor C_2, $q_2 = 0$

When C_1 (after being charged) is connected to C_2, the two capacitors will form a parallel combination. If C is the capacitance of the combination, then

$$C = C_1 + C_2 = 4 \times 10^{-6} + 2 \times 10^{-6} = 6 \times 10^{-6}\ C$$

Total charge on combination,

$$q = q_1 + q_2 = 1{\cdot}6 \times 10^{-13} + 0 = 1{\cdot}6 \times 10^{-3}\ C$$

If V is common potential, then

$$V = \frac{q}{C} = \frac{1{\cdot}6 \times 10^{-3}}{6 \times 10^{-6}} = \mathbf{266{\cdot}67\ V}$$

Problem 5.24. Four capacitors C_1, C_2, C_3 and C_4 are connected to a battery of 12 V as shown in Fig. 5.48. Find the potential difference between points A and B.

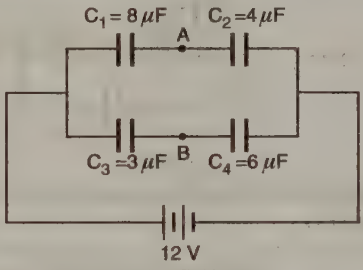

Fig. 5.48

Sol. Here, $C_1 = 8\ \mu F$; $C_2 = 4\ \mu F$; $C_3 = 3\ \mu F$ and $C_4 = 6\ \mu F$

Let V_A and V_B be potentials of points A and B respectively.

Then, potential difference across $C_1 = 12 - V_A$

potential difference across $C_2 = V_A - 0 = V_A$

potential difference across $C_3 = 12 - V_B$

and potential difference acorss $C_4 = V_B - 0 = V_B$

Since capacitors C_1 and C_2 are connected in series,

$$q_1 = q_2$$

i.e. $C_1(12 - V_A) = C_2 V_A$ or $8(12 - V_A) = 4 V_A$

or $V_A = 8$ V

Also, as capacitors C_3 and C_4 are in series,

$$q_3 = q_4$$

i.e. $C_3(12 - V_B) = C_4 V_B$ or $3(12 - V_B) = 6 V_B$

or $V_B = 4$ V

Therefore, potential difference between points A and B,

$$V_A - V_B = 8 - 4 = 4\ V$$

Type F. On Energy stored in a capacitor

Problem 5.25. The plates of a parallel plate capacitor have an area of 90 cm² each and are separated by 2·5 mm. The capacitor is charged by connecting it to a 400 volt supply. How much electrostatic energy is stored by the capacitor ? *(Text Problem)*

Sol. Here, $A = 90\ cm^2 = 90 \times 10^{-4}\ m^2$;

$$d = 2{\cdot}5\ mm = 2{\cdot}5 \times 10^{-3}\ m \ ;\ V = 400 \text{ volt}$$

Now, $$C = \frac{\varepsilon_0 A}{d} = \frac{8{\cdot}854 \times 10^{-12} \times 90 \times 10^{-4}}{2{\cdot}5 \times 10^{-3}}$$

$$= 3{\cdot}187 \times 10^{-11}\ F$$

Now, $$W = \frac{1}{2} C V^2 = \frac{1}{2} \times 3{\cdot}187 \times 10^{-11} \times (400)^2$$

$$= \mathbf{2{\cdot}55 \times 10^{-6}\ J}$$

Problem 5.26. Fig. 5.49 gives a circuit for a camera flash. A 2000 μF capacitor is charged by a 1·5 V cell. When a flash is required, the energy stored in the capacitor is made to discharge (actuated by an electronic trigger) through the discharge tube in 0·1 millisecond giving a powerful flash. Calculate the energy stored in the capacitor and the power of the flash. *(I.S.C.E. 1997)*

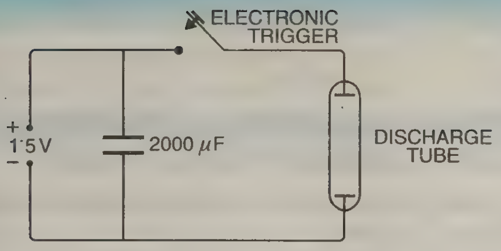

Fig. 5.49

ol. Here, $V = 1\cdot5$ volt ; $C = 2000\ \mu F = 2000 \times 10^{-6}$ F

herefore, energy stored in the capacitor,

$$U = \frac{1}{2} C V^2$$

$$= \frac{1}{2} \times 2000 \times 10^{-6} \times (1\cdot5)^2$$

$$= \mathbf{2\cdot25 \times 10^{-3}\ J}$$

he time in which the capacitor discharges in order to ce the flash,

$$t = 0\cdot1 \text{ millisecond} = 0\cdot1 \times 10^{-3} = 10^{-4} \text{ s}$$

lence, power of the flash, $P = \frac{U}{t} = \frac{2\cdot25 \times 10^{-3}}{10^{-4}} = \mathbf{22\cdot5\ W}$

G. On Loss of energy on sharing charges

roblem 5.27. A 4 μF capacitor is charged by a 200 V y. It is then disconnected from the supply and is cted to another uncharged 2 μF capacitor. How much ostatic energy of the first capacitor is lost in the form t and electromagnetic radiation ? *(Text Problem)*

ol. Here, $C_1 = 4\ \mu F = 4 \times 10^{-6}$ F ; $V_1 = 200$ V

nergy stored in the capacitor,

$$U_1 = \frac{1}{2} C_1 V_1^2 = \frac{1}{2} \times 4 \times 10^{-6} \times (200)^2$$

$$= 8 \times 10^{-2} \text{ J}$$

Vhen this charged capacitor is connected to another rged capacitor C_2 (= 2 μF), they will share charges, till tential differences across their plates become equal.

otal charge on the two capacitors,

$$q = C_1V_1 + C_2V_2 = 4 \times 10^{-6} \times 200 + 0 = 8 \times 10^{-4} \text{ C}$$

otal capacitance of the two capacitors,

$$C = C_1 + C_2 = 4\ \mu F + 2\ \mu F = 6\ \mu F = 6 \times 10^{-6} \text{ F}$$

herefore, common potential of the two capacitors,

$$V = \frac{q}{C} = \frac{8 \times 10^{-4}}{6 \times 10^{-6}} = \frac{400}{3} \text{ V}$$

nergy stored in the combination,

$$U_2 = \frac{1}{2} C V^2 = \frac{1}{2} \times 6 \times 10^{-6} \times \left(\frac{400}{3}\right)^2 = 5\cdot33 \times 10^{-2} \text{ J}$$

herefore, energy lost by capacitor C_1 (in the form of heat ectromagnetic radiation),

$$U_1 - U_2 = 8 \times 10^{-2} - 5\cdot33 \times 10^{-2} = \mathbf{2\cdot67 \times 10^{-2}\ J}$$

H. On Effect of dielectric

roblem 5.28. A parallel plate capacitor having plate ation of 3 mm possesses a capacitance of 17·7 pF. The tor is connected to a 100 V supply. Explain what would n, if a 3 mm thick mica sheet of dielectric constant 6 inserted between the plates (*a*) while the voltage y remains connected, (*b*) after the supply was nected. *(Text Problem)*

Sol. Here, dielectric constant of mica sheet, K = 6 ; capacitance of the capacitor, C = 17·7 pF

(a) When the voltage supply remains connected. The capacitance of the capacitor will become K times.

Therefore, $C' = K\,C = 6 \times 17\cdot7 = \mathbf{106\cdot2\ pF}$

The potential difference across the two plates of the capacitor will remain equal to supply voltage *i.e.* **100 V.**

The charge on capacitor,

$$q' = C'\,V = 106\cdot2 \times 10^{-12} \times 100$$

$$= \mathbf{1\cdot06 \times 10^{-8}\ C}$$

(b) After the voltage supply is disconnected. As calculated above, the capacitance of the capacitor,

$$C' = \mathbf{106\cdot2\ pF}$$

The potential difference will decrease on introducing mica sheet by a factor K, so that

$$V' = \frac{100}{6} = \mathbf{16\cdot67\ V}$$

The charge on the capacitor,

$$q' = C'V' = 106\cdot2 \times 10^{-12} \times 16\cdot67 = \mathbf{1\cdot77 \times 10^{-9}\ C}$$

Problem 5.29. A parallel plate capacitor is to be designed with a voltage rating 1 kV, using a material of dielectric constant 3 and dielectric strength of about 10^7 V m^{-1}. (Dielectric strength is the maximum electric field, a material can tolerate without breakdown *i.e.* without starting to conduct electricity through partial ionization). For safety, we should like the field never to exceed say 10% of the dielectric strength. What minimum area of the plate is required to have a capacitance of 50 pF ?

(P.S.S.C.E. 1995)

Sol. Here, K = 3 ; $\varepsilon_0 = 8\cdot854 \times 10^{-12}$ C^2 N^{-1} m^{-2}, dielectric strength = 10^7 V m^{-1} ; C = 50 pF = 50×10^{-12} F

Since electric field should not exceed 10% of the dielectric strength, we have

$$E = \frac{10^7 \times 10}{100} = 10^6 \text{ V m}^{-1},$$

Voltage rating = 1 kV = 10^3 V

$$\therefore \quad q = C \times \text{voltage rating} = 50 \times 10^{-12} \times 10^3$$

$$= 50 \times 10^{-9} \text{ C}$$

Now, $\quad C = \frac{\varepsilon_0 K A}{d} \quad$ or $\quad \frac{q}{V} = \frac{\varepsilon_0 K A}{d}$

or $\quad q = \varepsilon_0 K A \left(\frac{V}{d}\right) = \varepsilon_0 K A E$

Therefore, required area of the plates of the capacitor,

$$A = \frac{q}{\varepsilon_0 K E} = \frac{50 \times 10^{-9}}{8\cdot854 \times 10^{-12} \times 3 \times 10^6}$$

$$= 18\cdot8 \times 10^{-4} \text{ m}^2 = \mathbf{18\cdot8\ cm^2}$$

Type I. On Van de Graaff generator

Problem 5.30. In a Van de Graaff type generator, a spherical metal shell is to be a 15 × 10^5 V electrode. The dielectric strength of the gas surrounding the electrode is 5 × 10^7 V m^{-1}. What is the minimum radius of the spherical shell required ? *(Text Problem)*

Sol. The electric field and potential due to a charged shell of radius *r* are given by

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2} \qquad ...(i)$$

and $$V = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r} \qquad ...(ii)$$

Dividing equation (*ii*) by (*i*), we have

$$r = \frac{V}{E}$$

Here, $V = 15 \times 10^5$ V ; $E = 5 \times 10^7$ V m^{-1}

$$\therefore \quad r = \frac{15 \times 10^5}{5 \times 10^7} = 3 \times 10^{-2} \text{ m} = \mathbf{3 \text{ cm}}$$

TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 5.31. A plane capacitor is placed in a glass vessel and connected to a storage battery of e.m.f. 12 V as shown in Fig. 5.50. The area of the capacitor plates is 100 cm^2 and the distance between the plates is 1 mm. The switch S is closed. Determine the magnitude of the charge on the plate of the capacitor in the following cases :

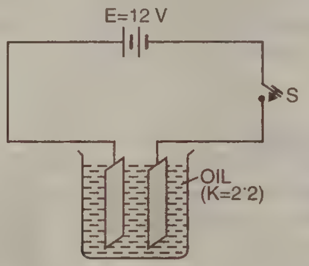

Fig. 5.50

(*a*) Switch S is opened and then the vessel is filled to the top with an oil of permittivity 2·2.

(*b*) The vessel is first filled with oil and then switch S is opened.

Also indicate as to how the intensity of electric field will change in the capacitor in these two cases, when the oil is poured in.

Sol. Here, $A = 100 \text{ cm}^2 = 100 \times 10^{-4} = 10^{-2} \text{ m}^2$; $K = 2{\cdot}2$; $d = 1 \text{ mm} = 10^{-3}$ m ; e.m.f. of battery, E = 12 V

Now, capacitance of the capacitor,

$$C = \frac{\varepsilon_0 A}{d} = \frac{8{\cdot}854 \times 10^{-12} \times 10^{-2}}{10^{-3}} = 8{\cdot}854 \times 10^{-11} \text{ F}$$

Therefore, charge on capacitor,

$$q = CE = 8{\cdot}854 \times 10^{-11} \times 12 = 1{\cdot}06 \times 10^{-19} \text{ C}$$

(*a*) When the switch is opened (battery disconnected) and the vessel is filled with oil, the charge on the plate of the capacitor will not change *i.e.* will remain **$1{\cdot}06 \times 10^{-9}$ C.**

The capacitance of the capacitor will become K (= 2·2) times *i.e.* **K C.**

It will result in the decrease of potential difference between the plates by a factor K. As a result, the intensity of electric field will also **decrease** by a factor K (= 2·2).

(*b*) When the oil is poured in the vessel with the switch closed (battery remains connected), the capacitance of the capacitor becomes K (= 2·2) times *i.e.* **K C** and the potential difference remains equal to e.m.f. of the battery *i.e.* E (= 12 V). Therefore, charge on the capacitor,

$$q' = C'E = (KC)E = 2{\cdot}2 \times 8{\cdot}854 \times 10^{-11} \times 12$$
$$= \mathbf{2{\cdot}34 \times 10^{-9} \text{ C}}$$

Since the potential difference between the plates remains unchanged, the intensity of electric field will also remain unchanged.

Problem 5.32. You are given three capacitors each of capacitance 9 μF. In how many ways can they be combined ? What will be the effective capacitance in each case ? *(Karnataka, 1988 S)*

Sol. Let the capacitance of each of the three capacitors C. Then, C = 9 μF

The three capacitors of equal capacitances can connected between two points A and B in the four ways shown in Fig. 5.51 :

Arrangement in Fig. 5.51 (a) : All the three capacitors connected in parallel. Therefore, effective capacitance,

$$C_1 = C + C + C = 3\,C = 3 \times 9 = \mathbf{27\ \mu F}$$

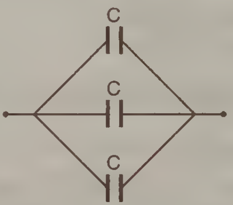

Fig. 5.51 (*a*)

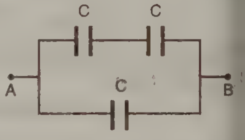

Fig. 5.51 (*b*)

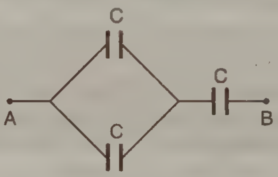

Fig. 5.51 (*c*)

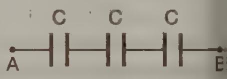

Fig. 5.51 (*d*)

Arrangement in Fig. 5.51 (b) : A series combination of capacitors have been put in parallel with the third capac If C′ is capacitance of the two capacitors in series, then

$$\frac{1}{C'} = \frac{1}{C} + \frac{1}{C} = \frac{2}{C} \quad \text{or} \quad C' = \frac{C}{2} = \frac{9}{2} = 4{\cdot}5$$

Therefore, effective capacitance of the combinatio given by

$$C_2 = C' + C = 4{\cdot}5 + 9 = \mathbf{13{\cdot}5\ \mu F}$$

Arrangement in Fig. 5.51 (c) : A parallel combinatio two capacitors has been put in series with the third capac If C″ is capacitance of the two capacitors in parallel, the

$$C'' = C + C = 9 + 9 = 18\ \mu F$$

Therefore, effective capacitance of the combinatio given by

$$\frac{1}{C_3} = \frac{1}{C''} + \frac{1}{C} = \frac{1}{18} + \frac{1}{9} = \frac{3}{18} \quad \text{or} \quad C_2 = \mathbf{6\ \mu F}$$

Arrangement in Fig. 5.51 (d) : All the three capacitors in series. The effective capacitance is given by

$$\frac{1}{C_4} = \frac{1}{C} + \frac{1}{C} + \frac{1}{C} = \frac{3}{C} \quad \text{or} \quad C_4 = \frac{C}{3} = \frac{9}{3} =$$

Problem 5.33. There are infinite number of capacit each of capacitance 1 μF. They are connected in ro such that number of capacitors in the first row, second r third row, fourth row, ... are respectively 1, 2, 4, 8 ..... , rows of these capacitors are then connected between po X and Y [Fig. 5.52]. Determine the equivalent capacitanc the network between points X and Y.

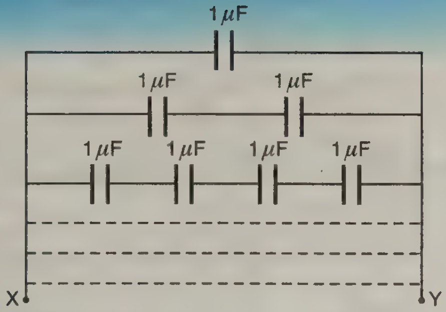

Fig. 5.52

Sol. Let C_1, C_2, C_3, C_4 ..... be capacitances of the capacitors tained in first row, second row, third row, fourth row, ... pectively. Since the rows of capacitances are connected in allel between points X and Y, the equivalent capacitance he network,

$$C = C_1 + C_2 + C_3 + C_4 + \text{.....} \qquad \text{...}(i)$$

Now, $C_1 = 1\,\mu F$; $C_2 = \frac{1 \times 1}{1+1} = \frac{1}{2}\,\mu F$;

$$\frac{1}{C_3} = \frac{1}{1} + \frac{1}{1} + \frac{1}{1} + \frac{1}{1} = 4 \quad \text{or} \quad C_3 = \frac{1}{4}\,\mu F$$

Similarly, $C_4 = \frac{1}{8}\,\mu F$; .....

Substituting for C_1, C_2, C_3, C_4, ...in equation (*i*), we get

$$C = 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \text{.....}$$

It is a geometric progression, whose first term $a = 1$ and nmon ratio $r = 1/2$.

The sum of infinite terms of a geometric progression is en by

$$S_\infty = \frac{a}{1-r}$$

$$\therefore \quad C = \frac{1}{1 - 1/2} = 2\,\mu F$$

Problem 5.34. Obtain the equivalent capacitance of the following network shown in Fig. 5.53. Given that = C_4 = 100 pF and $C_2 = C_3$ = 200 pF. For a 300 V supply, ermine the charge and voltage across each capacitor. (*Text Problem*)

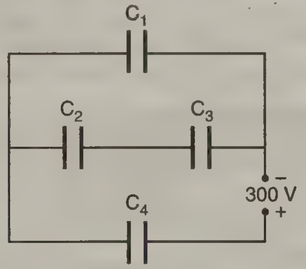

Fig. 5.53

Sol. The given network can be redrawn as shown in Fig. 4.

Here, $C_1 = C_4 = 100$ pF ; $C_2 = C_3 = 200$ pF

Let C_{23} be the capacitance of the series combination of and C_3. Then,

$$\frac{1}{C_{23}} = \frac{1}{C_2} + \frac{1}{C_3} = \frac{1}{200} + \frac{1}{200} = \frac{1}{100}$$

or $\quad C_{23} = 100$ pF

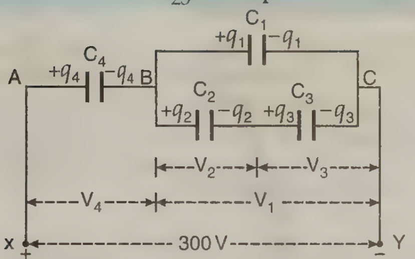

Fig. 5.54

Let C′ be the capacitance of the parallel combination of C_1 and C_{23}. Then,

$$C' = C_1 + C_{23} = 100 + 100 = 200 \text{ pF}$$

Let C be the capacitance of the series combination of C_4 and C′. Then,

$$\frac{1}{C} = \frac{1}{C_4} + \frac{1}{C'} = \frac{1}{100} + \frac{1}{200} = \frac{3}{200}$$

$$\text{or} \quad C = \frac{200}{3} \text{ pF} = \mathbf{66{\cdot}67 \text{ pF}}$$

Let q_4 be charge on the capacitor C_4. As C′ is in series with C_4, charge on C′ will also be equal to q_4.

$$\therefore \quad \text{P.D. across } C_4 = \frac{q_4}{C_4} = \frac{q_4}{100 \times 10^{-12}} \text{ V}$$

$$\text{and P.D. across } C' = \frac{q_4}{C'} = \frac{q_4}{200 \times 10^{-12}} \text{ V}$$

Now, P.D. across C_4 + P.D. across C′ = 300 V

$$\therefore \quad \frac{q_4}{100 \times 10^{-12}} + \frac{q_4}{200 \times 10^{-12}} = 300$$

$$\text{or} \quad \frac{3q_4}{200 \times 10^{-12}} = 300$$

$$\text{or} \quad q_4 = \frac{300 \times 200 \times 10^{-12}}{3} = \mathbf{2 \times 10^{-8}\ C}$$

$$\therefore \text{ P.D. across } C_4,\ V_4 = \frac{q_4}{C_4} = \frac{2 \times 10^{-8}}{100 \times 10^{-12}} = \mathbf{200\ V}$$

As C_1 and C_{23} are connected in parallel, potential difference across either of them is same.

$$\therefore \quad V_1 = \text{P.D. across } C_1 - \text{P.D. across } C_{23}$$
$$= 300 - 200 = \mathbf{100\ V}$$

Now, $q_1 = C_1 V_1 = 100 \times 10^{-12} \times 100 = \mathbf{10^{-8} C}$

As C_2 and C_3 have equal capacitances,

$$V_2 = V_3 = \frac{100}{2} = \mathbf{50\ V}$$

and $\quad q_2 = q_3 = 50 \times 200 \times 10^{-12} = \mathbf{10^{-8}\ C}$

Alternative method. Applying the principle of conservation of charge to the conductors meeting at point B, we have

$$q_1 + q_2 - q_4 = 0 \qquad \text{...}(i)$$

Also, applying the principle of conservation of charge to the conductors joining the negative plate of C_2 and the positive plate of C_3, we have

$$-q_2 + q_3 = 0$$

$$\text{or} \quad q_3 = q_2 \qquad \text{...}(ii)$$

The potential difference across the terminals A and B is same across the paths $XABC_1CY$ or $XABC_2C_3CY$ and is equal to 300 V.

Along path $XABC_1CY$:

$$\frac{q_4}{C_4}+\frac{q_1}{C_1}=300\text{ V} \quad\text{or}\quad \frac{q_4}{100\times10^{-12}}+\frac{q_1}{100\times10^{-12}}=300$$

or $\quad q_4+q_1=3\times10^{-8}\text{ C}$ ...(*iii*)

Along path $XABC_2C_3CY$:

$$\frac{q_4}{C_4}+\frac{q_2}{C_2}+\frac{q_3}{C_3}=300\text{ V}$$

or $$\frac{q_4}{100\times10^{-12}}+\frac{q_2}{200\times10^{-12}}+\frac{q_3}{200\times10^{-12}}=300$$

or $\quad 2\,q_4+q_2+q_3=6\times10^{-8}$ ...(*iv*)

From equations (*ii*) and (*iv*), we have

$$2\,q_4+q_2+q_2=6\times10^{-8}$$

or $\quad q_2+q_4=3\times10^{-8}$ ...(*v*)

Subtracting equation (*i*) from (*iii*), we have

$$q_4+q_1-(q_1+q_2-q_4)=3\times10^{-8}$$

or $\quad 2\,q_4-q_2=3\times10^{-8}$ ...(*vi*)

Adding equations (*v*) and (*vi*), we have

$$q_2+q_4+2\,q_4-q_2=3\times10^{-8}+3\times10^{-8}$$

or $\quad 3\,q_4=6\times10^{-8}$

or $\quad \mathbf{q_4=2\times10^{-8}}$

Substituting for q_4 in equation (*iii*), we have

$$q_1=3\times10^{-8}-q_4=3\times10^{-8}-2\times10^{-8}=\mathbf{10^{-8}\text{ C}}$$

Substituting for q_1 and q_4 in equation (*i*), we have

$$q_2=q_4-q_2=2\times10^{-8}-10^{-8}=\mathbf{10^{-8}\text{ C}}$$

From equation (*ii*), $q_3=q_2=\mathbf{10^{-8}\text{ C}}$

Now, $$V_1=\frac{q_1}{C_1}=\frac{10^{-8}}{100\times10^{-12}}=\mathbf{100\text{ V}},$$

$$V_2=\frac{q_2}{C_2}=\frac{10^{-8}}{200\times10^{-12}}=\mathbf{50\text{ V}},$$

$$V_3=\frac{q_3}{C_3}=\frac{10^{-8}}{200\times10^{-12}}=\mathbf{50\text{ V}}$$

and $$V_4=\frac{q_4}{C_4}=\frac{2\times10^{-8}}{100\times10^{-12}}=\mathbf{200\text{ V}}$$

If C is equivalent capacitance of the network, then C is equal to charge on the either terminal divided by the potential difference between the terminals. Hence,

$$C=\frac{q_4}{V} \qquad \left(\text{or take } C=\frac{q_1+q_3}{V}\right)$$

$$\therefore \quad C=\frac{2\times10^{-8}}{300}=\frac{200}{3}\times10^{-12}\text{ F}=\mathbf{\frac{200}{3}\text{ pF}}$$

Note. Students are advised to solve this numerical by both the methods so as to acquaint themselves with some new principles in electrostatics. It will help them to solve those problems, which otherwise cannot be solved by conventional methods.

Problem 5.35. Find the effective capacitance between points X and Y of the network of capacitors shown in Fig. 5.55. Given that $C_1=1\,\mu F$, $C_2=2\,\mu F$, $C_3=2\,\mu F$, $C_4=1\,\mu F$ and $C_5=1\,\mu F$. If a potential difference of 10^6 V is applied across X and Y, then calculate (*a*) charges on various capacitors, (*b*) voltages across the various capacitors and (*c*) the equivalent capacitance of the network.

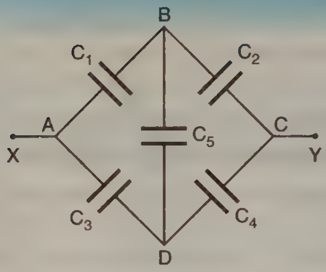

Fig. 5.55

Sol. Let q_1, q_2, q_3, q_4 and q_5 be charges on the capacitor C_1, C_2, C_3, C_4 and C_5 respectively, when a potential differenc of 10^6 V is applied across X and Y. Fig. 5.56 shows th distribution of charges on the various capacitors.

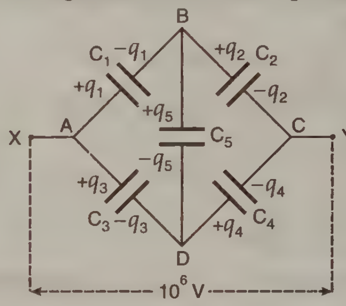

Fig. 5.56

(*a*) Applying law of conservation of charges for th conductors meeting at points B and D, we have

$-q_1+q_2+q_5=0$ ...(*i*

$-q_3+q_4-q_5=0$ ...(*i*

Now, the potential difference across the terminals X an Y is the same across paths XABCY, XADCY, XABDCY an XADBCY.

Across path XABCY:

$$\frac{q_1}{C_2}+\frac{q_2}{C_2}=10^6 \quad\text{or}\quad \frac{q_1}{10^{-6}}+\frac{q_2}{2\times10^{-6}}=10^6$$

or $\quad 2\,q_1+q_2=2$ ...(*ii*

Across path XADCY:

$$\frac{q_3}{C_3}+\frac{q_4}{C_4}=10^6 \quad\text{or}\quad \frac{q_3}{2\times10^{-6}}+\frac{q_4}{10^{-6}}=10^6$$

or $\quad q_3+2\,q_2=2$ ...(*i*

Across path XABDCY:

$$\frac{q_1}{C_1}+\frac{q_5}{C_5}+\frac{q_4}{C_4}=10^6 \text{ or } \frac{q_1}{10^{-6}}+\frac{q_5}{10^{-6}}+\frac{q_4}{10^{-6}}=10^6$$

or $\quad q_1+q_4+q_5=1$ ...(*v*

Across path XADBCY:

$$\frac{q_3}{C_1}+\left(-\frac{q_5}{C_5}\right)+\frac{q_2}{C_2}=10^6\text{ V}$$

or $$\frac{q_3}{2\times10^{-6}}-\frac{q_5}{10^{-6}}+\frac{q_2}{2\times10^{-6}}=10^6$$

or $\quad q_2+q_3-2\,q_5=2$ ...(*v*

From equation (*iii*), we have

$q_2=2-2\,q_1$ ...(*vi*

From equation (*i*), we have

$q_5=q_1-q_2=q_1-(2-2\,q_1)=3\,q_1-2$ ...(*vii*

From equation (*iv*), we have

$$q_3 = 2 - 2\,q_4 \qquad ...(ix)$$

From equations (*ii*) and (*ix*), we have

$$-2\,(2 - 2\,q_4) + q_4 - q_5 = 0$$

or

$$3\,q_4 = q_5 + 2$$

From equation (*viii*), substituting the value of q_5, we have

$$3\,q_4 = 3\,q_1 - 2 + 2 = 3\,q_1$$

or

$$q_4 = q_1$$

Therefore, from equation (*ix*), we have

$$q_3 = 2 - 2\,q_1 \qquad ...(x)$$

Substituting for q_4 and q_5 in equation (*v*), we have

$$q_1 + q_1 + (3\,q_1 - 2) = 1 \quad \text{or} \quad 5\,q_1 = 3$$

or

$$q_1 = \mathbf{0{\cdot}6\ C}$$

From equation (*vii*), we have

$$q_2 = 2 - 2\,q_1 = 2 - 2 \times 0{\cdot}6 = \mathbf{0{\cdot}8\ C}$$

From equation (*x*), we have

$$q_3 = 2 - 2\,q_1 = 2 - 2 \times 0{\cdot}6 = \mathbf{0{\cdot}8\ C}$$

Further, $q_4 = q_1 = \mathbf{0{\cdot}6\ C}$

From equation (*viii*), we have

$$q_5 = 3 \times 0{\cdot}6 - 2 = \mathbf{-0{\cdot}2\ C}$$

(*b*) Now,

$$V_1 = \frac{q_1}{C_1} = \frac{0{\cdot}6}{10^{-6}} = \mathbf{0{\cdot}6 \times 10^6\ V},$$

$$V_2 = \frac{q_2}{C_2} = \frac{0{\cdot}8}{2 \times 10^{-6}} = \mathbf{0{\cdot}4 \times 10^6\ V},$$

$$V_3 = \frac{q_3}{C_3} = \frac{0{\cdot}8}{2 \times 10^{-6}} = \mathbf{0{\cdot}4 \times 10^6\ V},$$

$$V_4 = \frac{q_4}{C_4} = \frac{0{\cdot}6}{10^{-6}} = \mathbf{0{\cdot}6 \times 10^6\ V}$$

and

$$V_5 = \frac{q_5}{C_5} = \frac{-0{\cdot}2}{10^{-6}} = \mathbf{-0{\cdot}2 \times 10^6\ V}$$

(*c*) If C is equivalent capacitance of the given network, en C is equal to charge on the either terminal divided by e potential difference between the terminals. Hence,

$$C = \frac{q_1 + q_3}{V} \qquad \left(\text{or take } C = \frac{q_2 + q_4}{V}\right)$$

$$\therefore \qquad C = \frac{0{\cdot}6 \times 0{\cdot}8}{10^6} = 1{\cdot}4 \times 10^{-6}\ \text{F} = \mathbf{1{\cdot}4\ \mu F}$$

Problem 5.36. The capacitance of a parallel plate capacitor with plate area A and separation *d* is C. The pace between the plates is filled with two wedges of ielectric constants K_1 and K_2 respectively [Fig. 5.57]. Find e capacitance of the resulting capacitor.

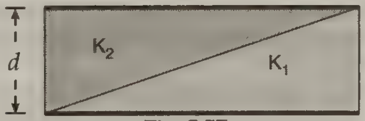

Fig. 5.57

Sol. Let each plate of the capacitor be of length *l*, eadth *b* and area A (= *l* × *b*). Fig. 5.58 shows the elementary portion of the capacitor between two vertical planes at distances *x* and *d* + *dx* from the left end of the plates. This elementary portion forms a series combination of two elementary capacitors of capacitances, say dC_1 and dC_2 :

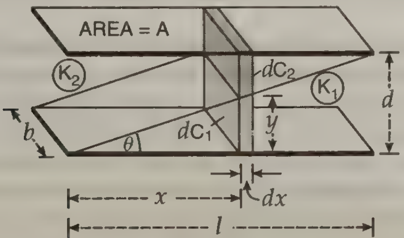

Fig. 5.58

(*i*) The two plates of the capacitor dC_1 are of area *b dx* and filled with a dielectric medium of dielectric constant K_1 and thickness *y*. Therefore,

$$dC_1 = \frac{\varepsilon_0\, K_1\, (b\, dx)}{y}$$

(*ii*) The two plates of the capacitor dC_2 are of area *b dx* and filled with a dielectric medium of dielectric constant K_2 and thickness (*d* − *y*). Therefore,

$$dC_2 = \frac{\varepsilon_0\, K_2\, (b\, dx)}{(d - y)}$$

Since the two elementary capacitors are in series, their resultant capacitance is given by

$$\frac{1}{dC} = \frac{1}{dC_1} + \frac{1}{dC_2} = \frac{y}{\varepsilon_0\, K_1\, (b\, dx)} + \frac{(d - y)}{\varepsilon_0\, K_2\, (b\, dx)}$$

$$= \frac{1}{\varepsilon_0\, (b\, dx)} \left[\frac{y}{K_1} + \frac{d - y}{K_2}\right]$$

$$= \frac{1}{\varepsilon_0\, (b\, dx)} \left[\frac{K_2\, y + K_1\, (d - y)}{K_1\, K_2}\right]$$

$$= \frac{K_1\, d + (K_2 - K_1)\, y}{\varepsilon_0\, K_1\, K_2\, b\, dx}$$

or

$$dC = \frac{\varepsilon_0\, K_1\, K_2\, b}{K_1\, d + (K_2 - K_1)\, y}\, dx$$

Therefore, capacitance of the whole capacitor is given by

$$C = \int_0^l dC = \int_0^l \frac{\varepsilon_0\, K_1\, K_2\, b}{K_1\, d + (K_2 - K_1)\, y}\, dx \qquad ...(i)$$

Now, *y* is function of *x* and is related to *x* as below :

$$\tan\theta = \frac{y}{x} = \frac{d}{l} \qquad \text{or} \qquad y = \frac{d}{l}\, x$$

Substituting for *y* in equation (*i*), we have

$$C = \varepsilon_0\, K_1\, K_2\, b \int_0^l \frac{1}{K_1\, d + (K_2 - K_1)\, \frac{d}{l}\, x}\, dx$$

$$= \frac{\varepsilon_0\, K_1\, K_2\, l \times b}{d} \int_0^l \frac{dx}{K_1\, l + (K_2 - K_1)\, x}$$

$$= \frac{\varepsilon_0\, K_1\, K_2\, A}{d} \int_0^l \frac{dx}{K_1\, l + (K_2 - K_1)\, x}$$

$$= \frac{\varepsilon_0\, K_1\, K_2\, A}{d} \left| \frac{\log_e\, [K_1\, l + (K_2 - K_1)\, x}{K_2 - K_1} \right|_0^l$$

$$= \frac{\varepsilon_0\, K_1\, K_2\, A}{(K_2 - K_1)\, d} \left| \log_e\, [K_1\, l + (K_2 - K_1)\, x \right|_0^l$$

$$= \frac{\varepsilon_0\, K_1\, K_2\, A}{(K_2 - K_1)\, d} \Big| \log_e\, [K_1\, l + (K_2 - K_1)\, l] - \log_e\, [K_1\, l + (K_2 - K_1)\, 0] \Big|$$

$$= \frac{\varepsilon_0 K_1 K_2 A}{(K_2 - K_1) d} \left| \log_e K_2 l - \log_e K_1 l \right| \qquad = \frac{\varepsilon_0 K_1 K_2 A}{(K_2 - K_1) d} \log_e \frac{K_2}{K_1}$$

FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 5.01. Is there any electric field inside a charged conductor ?

Ans. Inside a charged conductor, electric field is always zero.

Q. 5.02. What is meant by capacitance ? Give its SI unit. *(I.S.C.E. 1998)*

Or

Define capacitance. Give its SI unit.
(C.B.S.E. 1999 ; H.P.S.S.C.E. 1998 ; P.S.S.C.E. 1993)

Ans. *The capacitance of a conductor may be defined as the ratio of the electric charge on it to its electric potential due to the charge.*

SI unit of capacitance is **farad.**

Q. 5.03. What is one picofarad ?

Ans. 1 picofarad (pF) = 10^{-12} F

Q. 5.04. Name the physical quantity, whose SI unit is coulomb volt^{-1}. *(C.B.S.E. 1998)*

Ans. It is electrical capacitance.

Q. 5.05. What is a capacitor ? *(P.S.S.C.E. 1996 S)*

Ans. It is an arrangement of increasing the capacity of a conductor so as to store a large quantity of charge.

Q. 5.06. What meaning would you give to the capacitance of a single conductor ?

Ans. A single conductor also possesses capacitance. It is a capacitor, whose one plate is at infinity.

Q. 5.07. Can we give any desired amount of charge to a capacitor ?

Ans. No, the maximum charge that can be given to a capacitor is limited by the dielectric strength of the medium between the two plates of the capacitor.

Q. 5.08. On what factors does the capacity of a parallel plate capacitor with dielectric depend ? *(P.S.S.C.E. 1993)*

Ans. The capacitance of a parallel plate capacitor depends upon the area of its plates, separation between the plates and the dielectric constant of the dielectric between the plates.

Q. 5.09. Why is a parallel plate capacitor named so ? *(H.S.S.C.E. 1998)*

Ans. The plates of a parallel plate capacitor are plane and are placed parallel to each other. For this reason, it is called a parallel plate capacitor.

Q. 5.10. Three capacitors each of capacitance 2 μF are connected in series. Find the resultant capacitance in farad. *(H.S.S.C.E. 1996)*

Ans. Here, $C_1 = C_2 = C_3 = 2\ \mu F$

If C is capacitance, when the three capacitors are connected in series, then

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} = \frac{1}{2} + \frac{1}{2} + \frac{1}{2} = \frac{3}{2}$$

or $$C = \frac{2}{3}\ \mu F = 0{\cdot}067 \times 10^{-6}\ F$$

Q. 5.11. A capacitor of capacitance 20 μF is charged to a potential of 300 V. Calculate the energy stored in the capacitor. *(C.B.S.E. 1995)*

Ans. Here, $C = 20\ \mu F = 20 \times 10^{-6}$ F ; V = 300 volt

Energy stored,

$$U = \frac{1}{2} C V^2 = \frac{1}{2} \times 20 \times 10^{-6} \times (300)^2 = \mathbf{0{\cdot}9\ J}$$

Q. 5.12. How much work must be done to charge a μF capacitor, when the potential difference between th plate is 500 V ? *(H.S.S.C.E. 200*

Ans. Here, $C = 24\ \mu F = 24 \times 10^{-6}$ F and V = 500 V

$$\text{Therefore, work done} = \frac{1}{2} C V^2$$
$$= \frac{1}{2} \times 24 \times 10^{-6} \times (500)^2 = \mathbf{3\ J}$$

Q. 5.13. A capacitor is charged through a potenti difference of 200 V, when 0·1 C charge is stored in it. Ho much energy will it release, when it is discharged ? *(I.S.C.E. 199*

Ans. Here, V = 200 volt ; q = 0·1 C

$$\text{The energy stored, } U = \frac{1}{2} q V \times \frac{1}{2} \times 0{\cdot}1 \times 200 = 10\ J$$

On being discharged, the capacitor will release the san amount of energy *i.e.* **10 J.**

Q. 5.14. What should be the capacitance of a capacit capable of storing one joule of energy, when used with 100 V d.c. supply ? *(I.S.C.E. 199*

Ans. Here, U = 1 joule ; V = 100 volt

If C is capacitance of the capacitor, then

$$U = \frac{1}{2} C V^2$$

or $$C = \frac{2U}{V^2} = \frac{2 \times 1}{(100)^2} = \mathbf{2 \times 10^{-4}\ F}$$

Q. 5.15. In what form is the energy stored in a charg capacitor ? *(P.S.S.C.E. 1997*

Ans. In a charged capacitor energy is stored in the for of electric field between the two plates *i.e.* in the form electric energy.

Q. 5.16. Distinguish between polar and non-pol dielectrics. *(H.S.S.C.E. 199*

Ans. A dielectric, the molecules of which possess electr dipole moment even when electric field is not applied is call polar dielectric.

On the other hand, a dielectric, whose molecules do n possess permanent dipole moment is called non-polar.

Q. 5.17. What is a dielectric ? *(P.S.S.C.E. 200*

Ans. A material that does not conduct electricity but applying electric field, induced charges are produced on faces.

Q. 5.18. Guess a possible reason, why water has a mu greater dielectric constant (= 80) than say mica (= 6).

Ans. It is because, water molecules have permane dipole moment, while the molecules of mica do not have.

Q. 5.19. The dielectric constant of a conductor can taken to be infinitely large, infinitely small or optimu Which of the three alternatives is correct ?

Ans. When a conductor is placed inside an electric field, eld inside the conductor becomes zero. The dielectric ant, which is ratio of the strength of applied electric field e reduced value of electric field will be infinite for the uctor.

Q. 5.20. Write down the relation between dielectric tant and electric susceptibility.

Ans. The dielectric constant (K) and susceptibility of a ctric are related to each other by the relation

$$K = 1 + \chi$$

Q. 5.21. Define dielectric strength of the medium ?

(*H.S.S.C.E. 2001; H.P.S.S.C.E. 1999 S*)

Ans. The maximum value of electric field that a ectric can withstand, without the break down of the ctric, gives the measure of the dielectric strength.

Q. 5.22. Define dielectric constant in terms of the citance of a capacitor. (*C.B.S.E. 1995*)

Ans. *The dielectric constant of a dielectric medium is defined e ratio of the capacitance of the capacitor, when the dielectric he space between the plates to the capacitance, when there is um between the two plates of the capacitor.*

Q. 5.23. On inserting a dielectric between the plates of acitor, its capacitance is found to increase 5 times. What e relative permittivity of the dielectric ?(*I.S.C.E. 1995*)

Ans. When dielectric of relative permittivity ε_r is ted, the capacitance of the capacitor increases ε_r times. Since on inserting dielectric, capacitance increases 5 times, the relative permittivity of dielectric is 5.

Q. 5.24. In a parallel plate capacitor, the capacitance increases from 4 μF to 80 μF on introducing a dielectric medium between the plates. What is the dielectric constant of the medium ? (*C.B.S.E. 1996*)

Ans. Here, capacitance without dielectric, $C = 4\ \mu F$

and capacitance with dielectric, $C' = 80\ \mu F$

If K is dielectric constant of the dielectric medium, then

$$K = \frac{C'}{C} = \frac{80}{4} = 20$$

Q. 5.25. An air capacitor is given a charge of 2 μC raising its potential to 200 V. If on inserting a dielectric medium, its potential falls to 50 V, what is the dielectric constant of the medium ?

Ans. When dielectric is introduced, the potential between the plates of the capacitor decreases by a factor equal to dielectric constant. Therefore,

$$K = \frac{V}{V'} = \frac{200}{50} = 4$$

Q. 5.26. Why the Van de Graaff generator is enclosed inside an earth connected steel tank filled with air under pressure ?

Ans. It prevents the leakage of charge due to ionisation. The reason is that in air under pressure, as soon as free ions are produced, they recombine to form neutral air molecules.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 5.01. A metal of radius of 1 cm can not hold a charge columb. Why ? (*P.S.S.C.E. 1995 S*)

Ans. Refer to solved problem 5.02.

Q. 5.02. Two metallic spheres of same radii, one solid the other hollow are charged to the same potential. ch of the two will hold more charge ? Give reasons.

(*H.S.S.C.E. 1997 S ; I.I.T. 1974*)

Ans. Both the spheres will hold the same amount of ge. It is because, the two spheres possess equal citance. The capacitance of a sphere depends only on its is. It does not matter, whether a sphere is hollow or solid.

Q. 5.03. Why is not possible to make a spherical con- or of capacity one farad ? Explain. (*P.S.S.C.E. 2002*)

Ans. The capacitance of a spherical conductor of radius iven by

$$C = 4\pi\varepsilon_0 r$$

The radius of spherical conductor having capacitance given by

$$r = \frac{C}{4\pi\varepsilon_0} = 1 \times 9 \times 10^9 = 9 \times 10^9 \text{ m} = 9 \times 10^6 \text{ km}$$

Since one cannot have a spherical conductor of such a adius, it is not possible to make a spherical conductor of citance 1 F.

Q. 5.04. n small drops of same size are charged to V volt . They coalsece to form a bigger drop. Calculate the ntial of the bigger drop. (*P.S.S.C.E. 2001*)

Ans. Let r be the radius of each small drop. Then,

capacitance of each small drop, $C = 4\pi\varepsilon_0 r$

charge on each small drop, $q = CV = 4\pi\varepsilon_0 r \times V$

Total charge on n small drops, $Q = nq = n \times 4\pi\varepsilon_0 r \times V$

When n small drops coalesce, let R be the radius of the bigger drop formed. Since the volume of the bigger drop must be equal to that of n small drops,

$$\frac{4}{3}\pi R^3 = n \times \frac{4}{3}\pi r^3 \quad \text{or} \quad R = n^{1/3} r$$

Therefore, capacitance of the bigger drop

$$= 4\pi\varepsilon_0 R = 4\pi\varepsilon_0 \times n^{1/3} r$$

Since the bigger drop will possess the same charge as that on n small drops, potential of bigger drop

$$= \frac{n \times 4\pi\varepsilon_0 r \times V}{4\pi\varepsilon_0 n^{1/3} r} = n^{2/3} V$$

Q. 5.05. An uncharged insulated conductor A is brought near a charged insulated conductor B. What happens to charge and potential of B ? (*C.B.S.E. 2001 S*)

Ans. The charge on conductor B remains the same, but its potential gets lowered.

For details, refer to section 5.05–Principle of a capacitor.

Q. 5.06. In a parallel plate capacitor, how is the capacity affected, when without changing the charge :

(*i*) the distance between the plates is doubled ;

(*ii*) area of the plate is halved.

(*Pre-degree Kerala, 1992*)

Ans. (*i*) When the distance between the plates is doubled, the capacitance of the capacitor becomes half. It is because,

$$C \propto \frac{1}{d}$$

(*ii*) When the area of the plates is halved, the capacitance of the capacitor becomes half. It is because,

$$C \propto A$$

Q. 5.07. A parallel plate capacitor with air between the plates has a capacitance of 8 pF (1 pF = 10^{-12} F). What will be the capacitance, if the distance between the plates is reduced by half and the space between them is filled with a substance of dielectric constant 6 ? *(Text Question)*

Ans. Let A be the area of each plate and *d* be the distance between the two plates of the parallel plate capacitor. When air is between the two plates of the capacitor, then

$$C = \frac{\varepsilon_0 A}{d}$$

Here, $C = 8 \text{ pF} = 8 \times 10^{-12}$ F

$$\therefore \quad \frac{\varepsilon_0 A}{d} = 8 \times 10^{-12} \qquad \text{...}(i)$$

Suppose that the capacitance of the capacitor becomes C′, when distance between the plates is reduced to half *i.e.* $d' = \frac{d}{2}$ and the space between them is filled with a substance of dielectric constant K = 6. Then,

$$C' = \frac{\varepsilon_0 K A}{d'} = \frac{\varepsilon_0 \times 6 \times A}{d/2} = 12 \frac{\varepsilon_0 A}{d} \qquad \text{...}(ii)$$

From the equations (*i*) and (*ii*), we have

$$C' = 12 \times 8 \times 10^{-12} = 96 \times 10^{-12} \textbf{ F = 96 pF}$$

Q. 5.08. Two identical metal plates are given charges q_1 and $q_2 < q_1$) respectively. If they are now brought close together to form a parallel plate capacitor with capacitance C, what will be the potential difference between the plates ? *(I.I.T. 1999)*

Ans. Let each of the two plates be of area A. When they are placed at a distance *d*, the capacitance of the parallel plate capacitor formed,

$$C = \frac{\varepsilon_0 A}{d}$$

If E_1 and E_2 are electric fields due to the two plates, then net electric field between the two plates of the capacitor,

$$E = E_1 - E_2 = \frac{q_1/A}{2\varepsilon_0} - \frac{q_2/A}{2\varepsilon_0} = \frac{1}{2\varepsilon_0 A}(q_1 - q_2)$$

Potential difference between the two plates of the capacitor,

$$V = E\,d = \frac{1}{2\varepsilon_0 A}(q_1 - q_2) \times d = \frac{d}{2\varepsilon_0 A}(q_1 - q_2)$$

$$= \frac{q_1 - q_2}{2C}$$

Q. 5.09. Five identical capacitors, each of capacitance C, are connected between points X and Y as shown in Fig. 5.59. If the equivalent capacitance of the combination between points X and Y is 5 μF. calculate the capacitance of each capacitor.

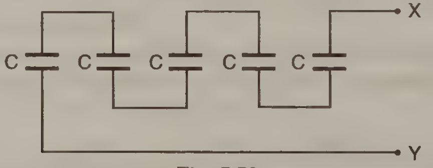

Fig. 5.59

Ans. It follows that the given arrangement of the five capacitors is simply their series arrangement.

Therefore, equivalent capacitance is given by

$$\frac{1}{C'} = \frac{1}{C} + \frac{1}{C} + \frac{1}{C} + \frac{1}{C} + \frac{1}{C} = \frac{5}{C}$$

or $\quad C' = \frac{C}{5}$

Q. 5.10. What is the effective capacitance of two ductors of capacitance 3 μF and 4 μF, when connected series ; (*ii*) in parallel ? *(Pre-degree Kerala,*

Ans. Here, $\quad C_1 = 3\,\mu\text{F}\,;\, C_2 = 4\,\mu\text{F}$

(*i*) In series, $\quad \frac{1}{C_s} = \frac{1}{3} + \frac{1}{4} = \frac{7}{12} \quad$ or $\quad C_s = \frac{12}{7}\,\mu\text{F}$

(*ii*) In parallel, $C_p = 3 + 4 = 7\,\mu\text{F}$

Q. 5.11. Three capacitors of equal capacitance, connected in series, have a net capacitance of C_1 and connected in parallel, have a capacitance of C_2. What be the value of C_1/C_2 ?

(H.S.S.C.E. 2002, 1998 ; C.B.S.E. 1995 ; P.S.S.C.E.

Ans. Let C be the capacitance of each of the capacitors and C_1 and C_2 be the capacitances of their and parallel combinations respectively.

Then, $\quad \frac{1}{C_1} = \frac{1}{C} + \frac{1}{C} + \frac{1}{C} = \frac{3}{C} \quad$ or $\quad C_1 =$

Also, $\quad C_2 = C + C + C = 3C$

$$\therefore \quad \frac{C_1}{C_2} = \frac{C/3}{3C} = \frac{1}{9}$$

Q. 5.12. Two capacitors of capacitances C_1 and C joined in series and this combination is joined in pa with a capacitor of capacitance C_3. Find the resu capacitance.

Ans. The three capacitors of capacitances C_1, C_2 ar are joined as shown in Fig. 5.60.

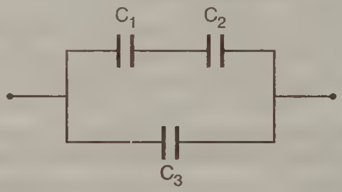

Fig. 5.60

The capacitance of series combination of C_1 and C

$$\frac{1}{C'} = \frac{1}{C_1} + \frac{1}{C_2} \quad \text{or} \quad C' = \frac{C_2\,C_2}{C_1 + C_2}$$

Therefore, resultant capacitance,

$$C = C' + C_3 = \frac{C_2\,C_2}{C_1 + C_2} + C_3$$

Q. 5.13. Two capacitors of capacitances 3 μF and respectively are joined in parallel and the combinati connected in series with a third capacitor of capacit 2 μF. Find the resultant capacitance. *(H.S.S.C.E.*

Ans. The three capacitors of capacitances 3 μF, 5 μ 2 μF are joined as shown in Fig. 5.61.

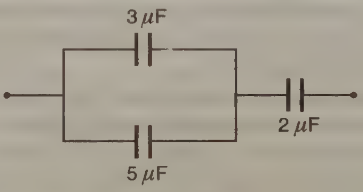

Fig. 5.61

The capacitance of parallel combination of 3 μF and 5 μF capacitors,

$$C' = 3 + 5 = 8\ \mu\text{F}$$

Therefore, resultant capacitance, $C = \dfrac{8 \times 2}{8 + 2} = 1{\cdot}6\ \mu\text{F}$

Q. 5.14. Three capacitors C_1, C_2 and C_3 are connected as shown in Fig. 5.62. Find the equivalent capacitance of the combination between points X and Y.

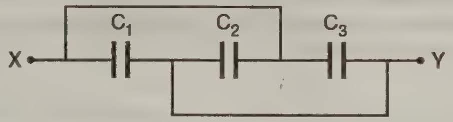

Fig. 5.62

Ans. The given arrangement of three capacitors is equivalent to their parallel combination as shown in Fig. 5.63.

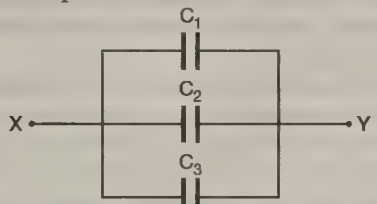

Fig. 5.63

Therefore, equivalent capacitance,

$$C = C_1 + C_2 + C_3$$

Q. 5.15. Find the equivalent capacitance of the arrangement of three capacitors shown in Fig. 5.64 between points X and Y.

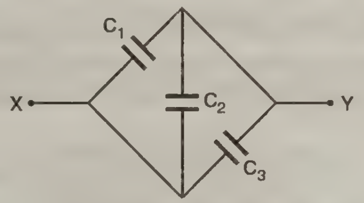

Fig. 5.64

Ans. The given arrangement of the three capacitors is equivalent to their parallel combination as shown in Fig. 5.65.

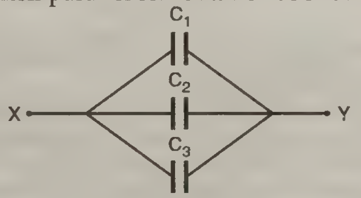

Fig. 5.65

Therefore, equivalent capacitance,

$$C = C_1 + C_2 + C_3$$

Q. 5.16. Four metallic plates, each with a surface area A are placed at a distance d apart from each other. The two other plates are connected to point X and the two inner plates to point Y as shown in Fig. 5.66. What is the equivalent capacitance of the system of plates ?

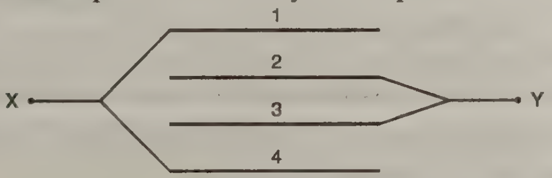

Fig. 5.66

Ans. The given arrangement of four plates is equivalent to the parallel combination of two capacitors C_1 and C_2. The capacitor C_1 is formed between plates 1 and 2, while the capacitor C_2 is formed between plates 4 and 3 [Fig. 5.67].

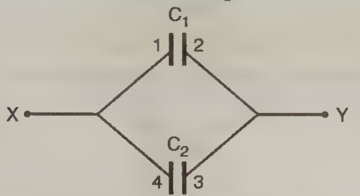

Fig. 5.67

Since area of each plate is A and separation between any two plates is d,

$$C_1 = C_2 = \frac{\varepsilon_0 A}{d}$$

Therefore, equivalent capacitance,

$$C = C_1 + C_2 = \frac{2\,\varepsilon_0 A}{d}$$

Q. 5.17. Three metallic plates, each with a surface area A, are placed at a distance d apart from each other. The two other plates are connected to each other as shown in Fig. 5.68. What is the equivalent capacitance of the given system of plates between points X and Y ?

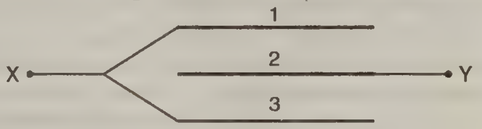

Fig. 5.68

Ans. The given arrangement of three plates is equivalent to parallel combination of two capacitors C_1 and C_2. The capacitor C_1 is formed between plates 1 and 2, while the capacitor C_2 is formed between plates 3 and 2 [Fig. 5.69].

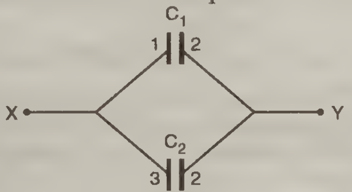

Fig. 5.69

Since area of each plate is A and separation between any two plates is d,

$$C_1 = C_2 = \frac{\varepsilon_0 A}{d}$$

Therefore, equivalent capacitance,

$$C = C_1 + C_2 = \frac{2\,\varepsilon_0 A}{d}$$

Q. 5.18. Four metallic plates, each with a surface area A, are placed at a distance d from each other. The alternate plates are connected to point X and Y as shown in Fig. 5.70. What is the equivalent capacitance of the system ?

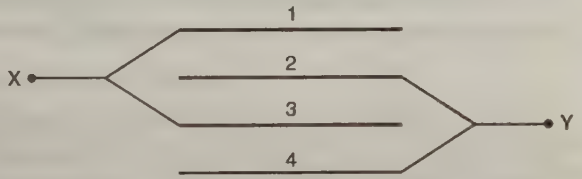

Fig. 5.70

Ans. The given arrangement of four plates is equivalent to the parallel combination of three capacitors C_1, C_2 and C_3.

The capacitor C_1 is formed between plates 1 and 2, C_2 between plates 3 and 2 and C_3 between plates 3 and 4 [Fig. 5.71].

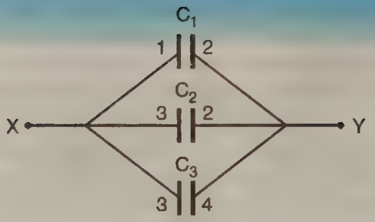

Fig. 5.71

Since area of each plate is A and separation between any two plates is d,

$$C_1 = C_2 = C_3 = \frac{\varepsilon_0 A}{d}$$

Therefore, equivalent capacitance,

$$C = C_1 + C_2 + C_3 = \frac{3\varepsilon_0 A}{d}$$

Q. 5.19. Two capacitors of capacitances 5 μF and 10 μF are charged to 16 volt and 13 volt respectively. What is the common potential, when they are connected in parallel ? (*Karnataka, 1985*)

Ans. Here, $C_1 = 5\ \mu F = 5 \times 10^{-6}$ F ;

$C_2 = 10\ \mu F = 10 \times 10^{-6}$ F ; $V_1 = 16$ volt ; $V_2 = 13$ volt

Therefore, charge on capacitor C_1,

$$q_1 = C_1 V_1 = 5 \times 10^{-6} \times 16 = 80 \times 10^{-6}\ C$$

Charge on capacitor C_2,

$$q_2 = C_2 V_2 = 10 \times 10^{-6} \times 13 = 130 \times 10^{-6}\ C$$

Let V be the common potential, when the two capacitors re connected in parallel. Then,

$$V = \frac{q_1 + q_2}{C_1 + C_2} = \frac{80 \times 10^{-6} + 130 \times 10^{-6}}{5 \times 10^{-6} + 10 \times 10^{-6}}$$

$$= \frac{210 \times 10^{-6}}{15 \times 10^{-6}} = \mathbf{14\ V}$$

Q. 5.20. Three capacitors of capacitances 10 μF, 20 μF and 30 μF are connected in parallel to a 100 V battery as shown in Fig. 5.72. Calculate the total energy stored in the capacitors. (*I.S.S.C.E. 1994*)

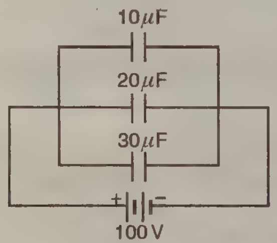

Fig. 5.72

Ans. Here, $C_1 = 10\ \mu F$; $C_2 = 20\ \mu F$; $C_3 = 30\ \mu F$

If C is their equivalent capacitance, then

$$C = C_1 + C_2 + C_3 = 10 + 20 + 30 = 60\ \mu F$$
$$= 60 \times 10^{-6}\ F$$

The total energy stored in the combination,

$$U = \frac{1}{2} C V^2 = \frac{1}{2} \times 60 \times 10^{-6} \times (100)^2 = \mathbf{0{\cdot}3\ J}$$

Q. 5.21. Capacitors P, Q and R have each a capacitance C. A battery can charge the capacitor P to a potential difference V. If after charging P, the battery is disconnected from it and the charged capacitor P is connected in following separate instances to Q and R (*i*) to Q in parallel, and (*ii*) to R in series, then what will be potential differences between the plates of P in the two instances ? (*C.B.S.E. 1997*)

Ans. When capacitor P is connected to a potential difference V, then

charge acquired by capacitor, $q = C V$

(i) When capacitor P is connected to Q in parallel : When the capacitors P and Q (each of capacitance C) are connected in parallel,

total capacitance = C + C = 2 C

total charge on the two capacitors = $q + 0 = q = C V$

Therefore, potential difference across each capacitor or capacitor P will become

$$V' = \frac{C V}{2 C} = \frac{V}{2}$$

(ii) When capacitor P is connected to R in series : When the capacitor P is connected to R in series, the circuit will not get completed and likewise sharing of charges does not take place. Therefore, potential difference across capacitor P will remain unchanged *i.e.* **V.**

Q. 5.22. How does a dielectric differ from an insulator?

Ans. Both the dielectrics and insulators cannot conduct electricity. However, in case of a dielectric, when an external field is applied ; induced charges appear on the faces of the dielectric. In other words, dielectrics have the property of transmitting electric effects without conducting.

Q. 5.23. Prove that atomic polarizability has the dimensions of volume.

Ans. The induced dipole moment of an atom is given by

$$p = \alpha \varepsilon_0 E$$

Therefore, atomic polarizability, $\alpha = \frac{p}{\varepsilon_0 E}$

Since the units of p, E and ε_0 are C m, N C^{-1} and C^2 N^{-1} m^2 respectively, the units of α are given by

$$[\alpha] = \left[\frac{p}{\varepsilon_0 E}\right] = \frac{C\,m}{C^2 N^{-1} m^{-2} \times N C^{-1}} = m^3$$

Hence, α has dimensions of volume.

Q. 5.24. What is the function of a dielectric in a capacitor ? (*P.S.S.C.E. 2002, 1999*)

Or

Explain, why presence of a dielectric increases capacitance of the capacitor. (*P.S.S.C.E. 1995*)

Ans. When a dielectric slab is introduced between the two plates of a capacitor, the electric field between the plates gets reduced due to polarisation of the dielectric. The reduced value of electric field is equivalent to a decreased value of potential difference between the plates. In order to make the potential difference again same, more charge has to be given to the capacitor. *i.e.* the capacitance of the capacitor increases.

Q. 5.25. For a given potential difference, a capacitor stores charge q, when dielectric of dielectric constant (K) is inserted between the two plates of capacitor. What is the new value of charge stored in the capacitor ? (*H.P.S.S.C.E. 2001*)

Ans. When a dielectric of dielectric constant (K) is inserted between the two plates of a capacitor, its capacitance increases K times, while the potential difference between the two plates decreases to $\frac{1}{K}$ of the original value. Therefore, new value of charge on the capacitor,

$$q' = C' \times V' = K C \times \frac{V}{K} = C V = q$$

i.e there is no effect on change on the capacitor.

Q. 5.26. Two equal dielectric slabs of dielectric stants K_1 and K_2 have been put between the plates of a acitor as shown in Fig. 5.73. If the area of each plate of capacitor is A and separation between them is *d*, find capacitance of the capacitor.

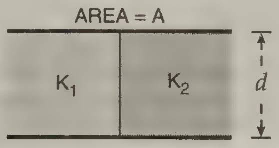

Fig. 5.73

Ans. The given arrangement is equivalent to parallel nbination of two capacitors, each of plate area A/2, plate aration *d*, such that one has medium of dielectric constant and other of dielectric constant K_2. If C_1 and C_2 are acitances of the two capacitors so formed, then

$$C_1 = \frac{\varepsilon_0 K_1 A/2}{d} = \frac{\varepsilon_0 K_1 A}{2d}$$

and $$C_2 = \frac{\varepsilon_0 K_2 A/2}{d} = \frac{\varepsilon_0 K_2 A}{2d}$$

If C is the capacitance of the capacitor, then

$$C = C_1 + C_2 = \frac{\varepsilon_0 K_1 A}{2d} + \frac{\varepsilon_0 K_2 A}{2d}$$

$$= \frac{\varepsilon_0 (K_1 + K_2) A}{2d}$$

Q. 5.27. Two dielectric slabs of dielectric constants K_1 l K_2 have been put in between the plates of a capacitor hown in Fig. 5.74. What would be the capacitance of the acitor ? *(H.S.S.C.E. 2001)*

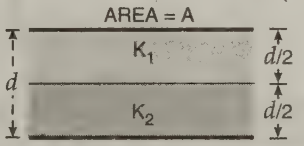

Fig. 5.74

Ans. The arrangement is equivalent to a series nbination of two capacitors, each of plate area of A, plate aration $d/2$, such that one has medium of dielectric stant K_1 and other of dielectric constant K_2. If C_1 and C_2 capacitances of the two capacitors so formed, then

$$C_1 = \frac{\varepsilon_0 K_1 A}{d/2} = \frac{2\varepsilon_0 K_1 A}{d}$$

and $$C_2 = \frac{\varepsilon_0 K_2 A}{d/2} = \frac{2\varepsilon_0 K_2 A}{d}$$

If C is the capacitance of the capacitor, then

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{d}{2\varepsilon_0 K_1 A} + \frac{d}{2\varepsilon_0 K_2 A}$$

$$= \frac{d}{2\varepsilon_0 A}\left(\frac{1}{K_1} + \frac{1}{K_2}\right) = \frac{d}{2\varepsilon_0 A}\left(\frac{K_1 + K_2}{K_1 K_2}\right)$$

or $$C = \frac{2\varepsilon_0 K_1 K_2 A}{(K_1 + K_2) d}$$

Q. 5.28. Is there any kind of material that when inserted between the plates of a capacitor reduces its capacitance ?

Ans. The dielectric constant K of a material is always greater than 1 and is defined as the ratio of the capacitance (C′) of the capacitor with dielectric between its plates to its capacitance (C) without the dielectric between the plates, Thus,

$$K = \frac{C'}{C}$$

As $K > 1, C' > C$ *i.e.* capacitance of a capacitor on placing the dielectric between the plates is always greater than the capacitance without the dielectric. Hence, there is no such material which when placed between the plates of a capacitor would reduce its capacitance.

Q. 5.29. If instead of a dielectric slab, we put a slab of metal between the plates of a capacitor keeping it insulated from them, what effect does it have on capacitance ?

Ans. When a slab of metal is put between the plates of a capacitor, its capacitance increases, provided the slab does not touch the plates of the capacitor. In case, the slab of metal touches the two plates, both plates become at the same potential and as a result, the capacitance of the capacitor becomes infinite.

Q. 5.30. Write the principle of Van de Graaff generator. *(H.S.S.C.E. 1997)*

Ans. Refer to section 5.20.

Q. 5.31. What limits maximum potential to which the hollow sphere in Van de Graaff generator can be raised ?

Ans. Because of leakage due to ionisation of surrounding air, when the rate of loss of charge becomes equal to the rate at which the charge is transferred to the sphere, the maximum potential of the sphere is reached.

Q. 5.32. Why should circuits containing capacitor be handled cautiously, even when there is no current ?

Ans. A capacitor does not discharge itself. In case the capacitor is connected in a circuit containing a source of high voltage, the capacitor charges itself to a very high potential. If some person handles such a capacitor without dicharging it first, he may get a severe shock.

TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 5.01. Two isolated metallic solid spheres of radii R and 2 R are charged, such that both of these have same face charge density σ. The spheres are located away from h other and connected by a thin conducting wire. Find new charge density on the two spheres. *(I.I.T. 1996)*

Ans. Let q_1 and q_2 be the initial charges on the spheres adii R and 2 R respectively. Then, total charge on the two eres,

$$q = q_1 + q_2 = 4\pi R^2 \sigma + 4\pi (2R)^2 \sigma$$

or $$q = 20\pi R^2 \sigma$$

When the two spheres are connected by a thin conducting wire, they will share charges, till their potential becomes the same. On reaching that stage, the charges on the two capacitors will be in the direct ratio of their capacitances. Therefore, if q'_1 and q'_2 are new values of charge on the two spheres, then

$$q_1' = q \times \frac{C_1}{C_1 + C_2} \quad \text{and} \quad q_2' = q \times \frac{C_2}{C_1 + C_2}$$

Since capacitance of a sphere is directly proportional to its radius,

$$q_1' = q \times \frac{R}{R+2R} = \frac{q}{3} = \frac{20}{3}\pi R^2 \sigma$$

and $$q_2' = q \times \frac{2R}{R+2R} = \frac{2q}{3} = \frac{40}{3}\pi R^2 \sigma$$

Therefore, new charge density of the two spheres,

$$\sigma_1' = \frac{q_1'}{4\pi R^2} = \frac{20\pi R^2 \sigma/3}{4\pi R^2} = \frac{5}{3}\sigma$$

and $$\sigma_2' = \frac{q_2'}{4\pi (2R)^2} = \frac{40\pi R^2 \sigma/3}{16\pi R^2} = \frac{5}{6}\sigma$$

Q. 5.02. A capacitor is made of a flat plate of area A and a second plate having a stair-like structure as shown in Fig. 5.75. If the width of each stair is A/3 and the height is *d*, find the capacitance of the arrangement.

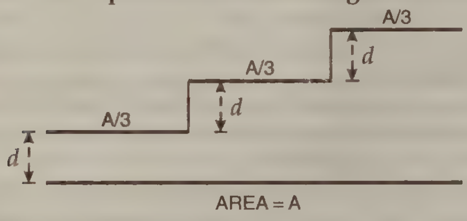

Fig. 5.75

Ans. The given arrangement of flat plate and the stair-like structure is equivalent to the parallel combination of three capacitors C_1, C_2 and C_3. The plate area of each of the three capacitors is A/3, while the separation between the plates of the three capacitors is *d*, 2 *d* and 3 *d* respectively.

$$\therefore \quad C_1 = \frac{\varepsilon_0 A/3}{d} = \frac{\varepsilon_0 A}{3d}\,;\; C_2 = \frac{\varepsilon_0 A/3}{2d} = \frac{\varepsilon_0 A}{6d}$$

and $$C_3 = \frac{\varepsilon_0 A/3}{3d} = \frac{\varepsilon_0 A}{9d}$$

Threfore, equivalent capacitance of the arrangement,

$$C = C_1 + C_2 + C_3 = \frac{\varepsilon_0 A}{3d} + \frac{\varepsilon_0 A}{6d} + \frac{\varepsilon_0 A}{9d}$$

$$= \frac{\varepsilon_0 A}{3d}\left(1 + \frac{1}{2} + \frac{1}{3}\right)$$

or $$C = \frac{11\varepsilon_0 A}{18d}$$

Q. 5.03. Five identical capacitor plates each of area A are arranged, such that adjacent are at a distance *d* apart. The plates are connected to a battery of e.m.f V volt [Fig. 5.76]. What is the magnitude and nature of charge on plates 1 and 4 ?

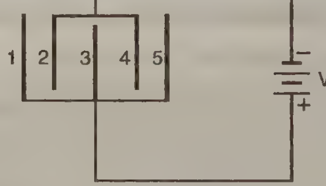

Fig. 5.76

Ans. The given arrangement of five plates is equivalent to the parallel combination of four capacitors namely C_1 (between plates 1 and 2), C_2 (between plates 2 and 3), C_3 (between plates 3 and 4) and C_4 (between plates 4 and 5). T positive plates of these capacitors are plates 1, 3, 3 an respectively.

Since area of each plate is A and separation between a two plates is *d*,

$$C_1 = C_2 = C_3 = C_4 = \frac{\varepsilon_0 A}{d}$$

The plate 1 is positive plate of capactor C_1. Therefo

charge on plate 1, $q = +C_1 V = +\frac{\varepsilon_0 A}{d} V$

The plate 4 acts as the negative plate of both capacitors C_3 and C_4. Therefore charge on plate 4,

$$q' = -(C_3 + C_4)V = -\frac{2\varepsilon_0 A}{d} V$$

Q. 5.04. Two parallel metal plates P and Q are inser at equal distances into a plane capacitor as shown Fig. 5.77. Plates A and B of the capacitor are connected battery of e.m.f. V.

(*a*) What are the potentials of each of the four plate

(*b*) How will the potentials of plates P and Q and intensities of the fields in each of the three spaces cha after plates P and Q have been connected by a wire ?

(*c*) What will happen to the charges on plates A B, when plates P and Q are connected with a wire.

(*d*) Will there be charges on the plates P and Q af connecting them with a wire ?

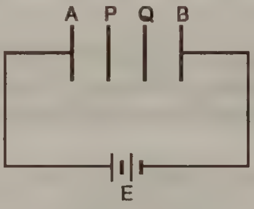

Fig. 5.77

Ans. (*a*) The plates P and Q divide the space betw plates A and B in three equal parts. Since V = E*d*, the potent of plates A, P, Q and B will be respectively V, 2 V/3, and 0.

(*b*) When the plates P and Q are connected with a w the space between plates A and B gets divided into two eq parts. Hence, potentials of plates A, P, Q and B will respectively V, V/2, V/2 and 0.

Since potential difference between plates A and P ; between plates Q and B has increased from V/3 to V/2, electric field between these plates will increase. As potential difference between plates P and Q is zero, the elec field will also be zero.

(*c*) Since potential difference between plates A and P between plates Q and B has increased, the charge on pla A and B will increase.

(*d*) Yes. Plate P will have a positive charge and plat will have a negative charge.

Q. 5.05. Prove that energy stored per unit volume i capacitor is given by $\frac{1}{2}\varepsilon_0 E^2$, where E is electric fi of the capacitor.

Ans. Consider a parallel plate capacitor having ea plate of area A and separated by a distance *d*. Then,

capacitance of parallel plate capacitor, $C = \frac{\varepsilon_0 A}{d}$

If σ is surface charge density of the plates of the capacitor, n electric field between the plates of capacitor,

$$E = \frac{\sigma}{\varepsilon_0}$$

or $$\sigma = \varepsilon_0 E$$

Also, charge on the plate of the capacitor,

$$q = \sigma A = \varepsilon_0 E A$$

Now, energy stored in the capacitor, $U = \frac{1}{2}\frac{q^2}{C}$

Substituting for q and C, we have

$$U = \frac{1}{2}(\varepsilon_0 E A)^2 \Big/ \frac{\varepsilon_0 A}{d} = \frac{1}{2}\varepsilon_0 E^2 A d$$

Now, $A d$ = volume of the capacitor

Therefore, energy stored per unit volume in the capacitor

$$= \frac{1}{2}\varepsilon_0 E^2$$

Q. 5.06. Prove that the total energy stored in a series combination of capacitors is equal to the sum of ergies stored in the individual capacitors.

Ans. Suppose that three capacitors of capacitances C_1, C_2 d C_3 are connected in series to a battery. The equivalent pacitance of the series combination is given by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}$$

Further, when a series combination of capacitors is arged through a battery, the charge on the left plate of each pacitor is q, while induced charges $-q$ and $+q$ are produced the right plate of each capacitor. Thus, net charge stored the series combination is just q.

Therefore, total energy stored in series combination,

$$U = \frac{1}{2}\frac{q^2}{C} = \frac{1}{2}q^2\left(\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}\right)$$

$$= \frac{1}{2}\frac{q^2}{C_1} + \frac{1}{2}\frac{q^2}{C_2} + \frac{1}{2}\frac{q^2}{C_3}$$

or $$U = U_1 + U_2 + U_3$$

Thus, energy stored in series combination of the pacitors is equal to the sum of the energies stored in the dividual capacitors.

Q. 5.07. Prove that the total energy stored in a parallel combination of capacitors is equal to the sum of the ergies stored in the individual capacitors.

Ans. When three capacitors of capacitances C_1, C_2 and are connected in parallel, the resultant capacitance of the rallel combination is given by

$$C = C_1 + C_2 + C_3$$

Further, when a parallel combination of capacitors is arged through a battery, the potential difference across the o plates of each capacitor is equal to the applied voltage Therefore, total energy stored in the parallel combination,

$$U = \frac{1}{2}CV^2 = \frac{1}{2}(C_1 + C_2 + C_3)V^2$$

$$= \frac{1}{2}C_1V^2 + \frac{1}{2}C_2V^2 + \frac{1}{2}C_3V^2$$

or $$U = U_2 + U_2 + U_3$$

Therefore, total energy stored in parallel combination of e capacitors is also equal to the sum of the energies stored individual capacitors.

Q. 5.08. The plate A of a parallel plate capacitor is connected to a spring of force constant k and can move, while the plate B is fixed. The arrangement is held between two rigid supports as shown in Fig. 5.78. If a charge $+q$ is placed on plate A and $-q$ on plate B, by how much does the spring elongate ?

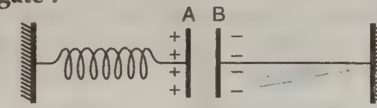

Fig. 5.78

Ans. Suppose that the two plates of the capacitors attract each other with a force F and as a result, the spring elongates by an amount l. Then,

$$F = -k\,l \qquad ...(i)$$

If the area of each of the two plates of the capacitor is A and separation between the plates is x, then capacitance of the capacitor,

$$C = \frac{\varepsilon_0 A}{x} \qquad ...(ii)$$

The energy stored in the capacitor,

$$U = \frac{1}{2}\frac{q^2}{C}$$

Using equation (*ii*), we have

$$U = \frac{q^2 x}{2\varepsilon_0 A}$$

As the electrostatic force (F) is a conservative force, it can be expressed as negative gradient of corresponding potential *i.e.*

$$F = -\frac{\partial U}{\partial x} = -\frac{\partial}{\partial x}\left(\frac{q^2 x}{2\varepsilon_0 A}\right)$$

or $$F = -\frac{q^2}{2\varepsilon_0 A} \qquad ...(iii)$$

The negative sign indicates that force between the plates of the capacitor is attractive in nature.

From equations (*i*) and (*ii*), we have

$$-k\,l = -\frac{q^2}{2\varepsilon_0 A} \quad \text{or} \quad l = \frac{q^2}{2\varepsilon_0 A}$$

Q. 5.09. If a parallel plate capacitor of capacitance C is kept connected to a supply voltage V to just fill the space and then a dielectric slab is inserted between the plates. What will be the change in the capacitance, potential difference, the charge, electric field and the energy stored ?

Ans. Let K be dielectric constant of the dielectric slab and q, E and U be charge on capacitor, electric field between plates and energy stored in the capacitor before inserting the slab.

On inserting dielectric slab :

The capacitance of the capacitor will become

$C' = K C$ **(increases)**

Since the capacitor is kept connected to the supply voltage, potential difference will remain **unchanged** *i.e.* **V.**

The charge on capacitor will become,

$q' = C'V = KCV = Kq$ **(increases)**

It may be pointed out that as battery remains connected to the capacitor, it can draw more charge from the battery.

Since potential difference between plates does not change, electric field will also remain **unchanged.**

The energy stored in the capacitor will become

$$U' = \frac{1}{2} C' V^2 = \frac{1}{2} K C V^2 = \mathbf{K\,U} \textbf{ (increases)}$$

Q. 5.10. A parallel plate capacitor of capacitance C is charged to a potential difference V and then the battery is disconnected. Now a dielectric slab of the dimensions equal to the spacing between the plates is inserted between the plates. What are the changes, if any, in the capacitance, charge, potential difference, electric field and the energy stored ?

Ans. Let K be dielectric constant of the slab and q, E and U be charge on the plates of the capacitor, electric field between the plates and energy stored in the capacitor before inserting the slab.

On inserting dielectric slab :

The capacitance of capacitor will become,

$$C' = KC \qquad \textbf{(increases)}$$

Since battery has been disconnected, the charge c capacitor will remain the same.

P.D. between the plates, $V' = \frac{q}{C'} = \frac{q}{KC} = \frac{V}{K}$ **(decrease**

Electric field between the plates,

$$E' = \frac{V'}{d} = \frac{V}{K} d = \frac{E}{K} \qquad \textbf{(decreases)}$$

Energy stored in the capacitor,

$$U' = \frac{1}{2} C' V'^2 = \frac{1}{2} (KC) \left(\frac{V}{K}\right)^2 = \frac{1}{K}\left(\frac{1}{2} C V^2\right)$$

$$= \frac{U}{K} \qquad \textbf{(decreases)}$$

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. Define capacitance. Give its units. Show that the capacitance of an insulated spherical conductor is $4\pi\varepsilon_0$ times the radius of the spherical conductor.
2. What is a capacitor ? Explain its principle. *(P.S.S.C.E. 2002, 2001, 2000, 1999)*
3. Explain the principle of a capacitor. *(P.S.S.C.E. 1997 ; C.B.S.E. 1994)*
4. Explain the action of a capacitor. *(P.S.S.C.E. 1994)*
5. What are the factors on which capacitance of a parallel plate capacitor depends ? Give the corresponding relation. *(C.B.S.E. 1991)*
6. Obtain a relation for the capacitance of a parallel plate capacitor. *(P.S.S.C.E. 1999 S, 1999, 1994 ; C.B.S.E. 1994 ; H.S.S.C.E. 1994)*

1. What is a capacitor ? Explain its principle. Obtain a relation for the capacitance of a parallel plate capacitor. (P.S.S.C.E. 2000, 1996 S)
2. Explain the principle of a capacitor. Derive an expression for the capacitance of a parallel plate capacitor. (H.S.S.C.E. 2002)
3. What is a spherical capacitor ? Derive expression for its capacitance.
4. Define capacitance. Derive an expression for the capacitance of a cylindrical capacitor. (C.B.S.E. 1992)
5. What is a capacitor ? Derive expression for the total capacitance, when three capacitors of capacitances C_1, C_2 and C_3 are connected in (*i*) series (*ii*) parallel. (H.S.S.C.E. 2002)
6. Define capacitance of a capacitor. Give its SI unit. Prove that the total electrostatic energy stored in a parallel plate capacitor is $\frac{1}{2} C V^2$. (C.B.S.E. 2001 S, 1996)
7. Derive the expression for the capacitance of a parallel plate capacitor with a dielectric medium of dielectric contant K between its plates. Obtain also the expression for the energy stored in the above case. (C.B.S.E. 2001 S)
8. Define capacitance of a capacitor. Give its SI unit. Derive an expression for the electrostatic energy stored in a charged capacitor. (P.S.S.C.E. 1999 S)
9. How does the total energy stored by the capacitor change, when the medium of air is replaced by a medium of dielectric constant K ? Explain. (C.B.S.E. 1998)
10. Derive the expression for the energy stored in a charged capacitor. Show that there is always a loss of energy on connecting the two charged capacitors having capacitances C_1, C_2 and potentials V_1, V_2. (C.B.S.E. 1998 S)
11. Derive an expression for the energy stored in a parallel plate capacitor. Assuming that the capacitor is disconnected from the battery, explain how the (*i*) capacitance (*ii*) potential difference across the plates and (*iii*) energy stored in the parallel plate capacitor change, when a medium of dielectric constant K is introduced between the plates. (C.B.S.E. 2001, 2000)
12. Derive an expression for the energy stored in a parallel plate capacitor. A parallel plate capacitor with air as dielectric is charged by a d.c. source to a potential V. Without disconnecting the capacitor from the source, air is replaced by another dielectric medium of dielectric constant 10. State with reasons, how does (*i*) electric field between the plates and (*ii*) energy stored in the capacitor change. (C.B.S.E. 2002)
13. Deduce an expression for the capacitance of a parallel plate capacitor, when dielectric slab is inserted between its plates. Assume the slab thickness to be less than the plate separation. (H.P.S.S.C.E. 2002)
14. Draw a labelled diagram of a Van de Graaff generator. Give its principle and explain its working. (C.B.S.E. 1996)
15. Give the principle and explain the working of a Van de Graaff generator with the help of a labelled diagram. (C.B.S.E. 1998 S, 1997)
16. Discuss the principle, construction and working of Van de Graaff generator. (H.S.S.C.E. 2002, 20021, 1993 ; P.S.S.C.E. 2001, 1991 ; C.B.S.E. 1999, 1990)

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

ype A. On Capacitance of a conductor

1. When electrons equal to Avogadro number are transferred from one conductor to another, a potential difference of 10^6 V appears between them. Calculate the capacitance of the system of two conductors. [**Ans.** $9{\cdot}63 \times 10^{-2}$ F]
2. A charged spherical conductor has a surface density of $0{\cdot}07$ C cm^{-2}. When the charge is increased by 4·4 C, the surface density changes by $0{\cdot}084$ C cm^{-1}. Find the initial charge and capacitance of the spherical conductor. [**Ans.** 22 C, $5{\cdot}56 \times 10^{-12}$ F]
3. If 64 small mercury drops each charged to 220 V coalesce, what will be the potential of bigger drop ? [**Ans.** 3520 V]
4. Twenty seven spherical droplets of radius 3 mm and each carrying 10^{-12} C of charge are combined to form a bigger drop. Find the capacitance of the bigger drop. (H.S.C.C.E 2001) [**Ans.** 10^{-12} F]
5. N drops of mercury of equal radii and possessing equal charges combine to form a big drop. Compare the charge, capacitance and potential of bigger drop with the corresponding quantities of individual drop. [**Ans.** N, $N^{1/3}$, $N^{2/3}$]
6. The radii of two charged metallic spheres are 5 cm and 10 cm. Each has a charge of 75 μC. They are connected by a conducting wire. Calculate (*a*) common potential of the spheres after connecting and (*b*) amount of charge transferred. [**Ans.** (*a*) 9×10^6 V ; (*b*) 25 μC]

Type B. On Capacitance of a capacitor

7. What distance should the two plates each of area 0·2 m × 0·1 m of an air capacitor be placed in order to have the same capacitance as a spherical conductor of radius 0·5 m ? [**Ans.** $3{\cdot}183 \times 10^{-3}$ m]
8. An air capacitor has plates of 6 cm diameter. At what distance should the plates be placed so as to have the same capacitance as sphere of diameter of 90 cm ? [**Ans.** 0·25 mm]
9. A parallel plate capacitor has each plate of 0·06 m diameter separated by 0·05 cm of air. What is the capacitance of the capacitor ? What would be the radius of a sphere having the same capacitance ? [**Ans.** 50 pF, 0·45 m]
10. In a parallel plate capacitor with air between the plates, each plate has an area 6×10^{-3} m^2 and the distance between the plates is 3 mm. Calculate the capacitance of the capacitor. If this capacitor is connected to a 100 volt supply, what is the charge on each plate of the capacitor ? (*Text Problem*) [**Ans.** $1{\cdot}77 \times 10^{-9}$ V]
11. A parallel plate capacitor has two plates of sides 0·055 m and 0·04 m of air. Their distance apart is 0·7 mm. The dielectric constant of the medium in between is 4. Find the capacitance of the capacitor. (*Karnataka, 1985 S*) [**Ans.** $1{\cdot}1 \times 10^{-10}$ F]
12. A parallel plate capacitor has plates of area 0·02 m^2 and separation between the plates 1 mm. What potential difference will be developed, if a charge of 1 *n*C is given

to the capacitor ? If the plate separation is now increased to 2 mm, what will be the new potential difference ? **[Ans.** 5·65 V, 11·3 V]

Type C. On Capacitance of a spherical capacitor

13. Calculate the capacitance of a spherical capacitor, if the diameter of inner sphere is 0 · 2 m and that of the outer sphere is 0·3 m, the space between them being filled with a liquid having dielectric constant 20. **[Ans.** 1333 pF]

14. A spherical capacitor has 10 cm and 12 cm as the radii of inner and outer spheres. The space between the two is filled with a dielectric of dielectric constant 5. Find its capacitance, when the inner sphere is earthed. **[Ans.** 333 pF]

15. A spherical capacitor has an outer sphere of radius 0 · 15 m and the inner sphere of radius 0·1 m. The outer sphere is earthed and the inner sphere is given a charge of 6 μC. The space between the concentric spheres is filled with a material of dielectric constant 18. Calculate the capacitance and potential of the inner sphere. **[Ans.** 6×10^{-10} F, 10^4 V]

Type D. On capacitance of cylindrical capacitors

16. The inner and outer radii of a coaxial cable are 0 · 1 mm and 0·6 mm respectively. If the core material has dielectric constant 12, calculate the capacitance per metre of the cable. **[Ans.** $3{\cdot}725 \times 10^{-10}$ F m^{-1}]

17. A cable consisting of a wire 3 mm in diameter and insulated with 3 mm thick dielectric of relative permittivity 7 is placed in water. Calculate the capacitance of 1 km length of the cable. **[Ans.** 0·354 μF]

Type E. On Grouping of capacitors

18. Two spheres of radii 2 cm and 7 cm are connected together. What is the total capacitance of the combination ? **[Ans.** 1·73 pF (in series), 10·0 pF (in parallel)]

19. Three capacitors of capacitances 2 μF, 3 μF and 4 μF are connected (*i*) in series ; (*ii*) in parallel. Compare the effective capacitances in the two cases. **[Ans.** 4 : 39]

20. The capacitances of three capacitors are in the ratio 1 : 2 : 3. Their equivalent capacitance in parallel is gerater than their equivalent capacitance in series by 60/11 μF. Calculate their individual capacitances. **[Ans.** 1 μF, 2 μF ; 3 μF]

21. Three capacitors of capacitances 1, 3 and 6 microfarad and connected so that the second and the third are in series and the first is in parallel with them. Calculate the capacitance of the combination. **[Ans.** 3 μF]

22. Three capacitors, each of capacitance 6 μF are connected together in series and are also connected in series with three capacitors of values 2 μF, 4 μF and 2 μF, which are grouped together in parallel. Calculate the total combined capacitance. **[Ans.** 1·6 μF]

23. Calculate the capacitance of the capacitor C in the network shown in Fig. 5.79. The equivalent capacitance of the combination between P and Q is 30 μF. (*C.B.S.E. 1995*) **[Ans.** 60 μF]

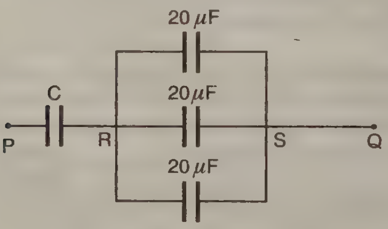

Fig. 5.79

24. Find the equivalent capacitance of the system shown in Fig. 5.80 between the points X and Y.

$$\left[\textbf{Ans.}\ C + \frac{2C_1C_2}{C_1+C_2}\right]$$

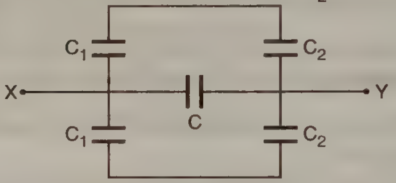

Fig. 5.80

25. Four capacitors are connected as shown in Fig. 5.81. Calculate the equivalent capacitance between the points X and Y. (*C.B.S.E. 2000*) **[Ans.** 15 μF]

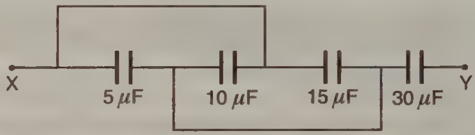

Fig. 5.81

26. Find the resultant capacitance between points X and Y of the combination of capacitors shown in Fig. 5.82. (*H.S.S.C.E. 2001*) **[Ans.** 2·5 μF]

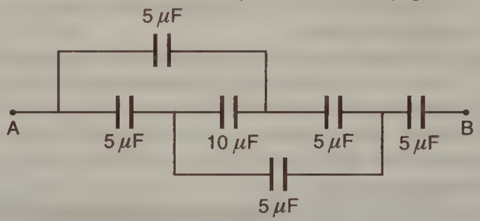

Fig. 5.82

27. The outer cylinders of two cylindrical capacitors of capacitance 2·2 μF each are kept in contact and the inner cylinders are connected through a wire. A battery of e.m.f 10 V is connected as shown in Fig. 5.83. Find the total charge supplied by the battery to the inner cylinders. **[Ans.** 44 μC]

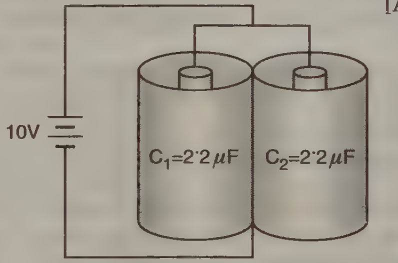

Fig. 5.83

28. Find the equivalent capacitance between the points X and Y of the network of capacitors shown in Fig. 5.84. **[Ans.** 1 μF]

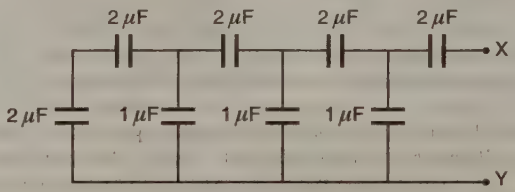

Fig. 5.84

29. A 0·5 μF capacitor connected in parallel to 0·75 μF capacitor and this combination is joined to a 100 volt d.c.

source. Calculate charge taken from the source and charge on each capacitor. (*H.S.S.C.E. 1997*)
[**Ans.** 125 μC, 50 μC, 75 μC]

0. Calculate the capacitance of a combination of three capacitors of capacitances 8, 12 and 24 μC, when they are joined in (*i*) series (*ii*) parallel. Find the charge on each plate in the series arrangement, if the potential difference across the system is 100 volt.
[**Ans.** (*i*) 4 μF, (*ii*) 44 μF ; 4×10^{-4} C]

1. In the network of capacitors shown in Fig. 5.85, find (*i*) equivalent capacitance and (*ii*) total charge.
(*P.S.S.C.E. 1993*) [**Ans.** (*i*) 66·67 pF ; (*ii*) 2×10^{-8} C]

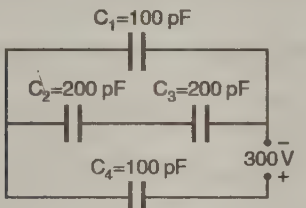

Fig. 5.85

2. A network of four 10 μF capacitors is connected to a 500 V supply as shown in Fig. 5.86. Determine the (*a*) equivalent capacitance of the network and (*b*) charge on each capacitor.
[**Ans.** (*a*) 13·33 μF (*b*) $q_1 = q_2 = q_3 = 1{\cdot}67 \times 10^{-3}$ C, $q_4 = 5{\cdot}0 \times 10^{-3}$ C]

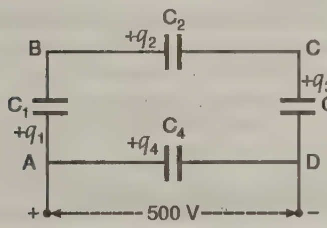

Fig. 5.86

3. The capacitors C_1, C_2 and C_3 are connected as shown in Fig. 5.87 to a 100 V d.c. supply. If $C_1 = 2$ μF, $C_2 = 3$ μF and $C_3 = 5$ μF, find potential difference across each capacitor [**Ans.** $V_1 = 80$ V, $V_2 = V_3 = 20$ V]

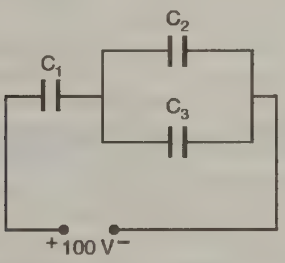

Fig. 5.87

4. Three capacitors have capacitances 10 μF, 50 μF and 25 μF respectively. Calculate (*i*) charge on each, when connected in parallel to a 250 V supply, (*ii*) total capacitance and (*iii*) potential difference across each, when connected in series.
[**Ans.** (*i*) $q_1 = 2500$ μC, $q_2 = 12500$ μC, $q_3 = 6250$ μC ; (*ii*) 85 μF ; (*iii*) $V_1 = 156{\cdot}25$ V, $V_2 = 31{\cdot}25$ V, $V_3 = 62{\cdot}5$ V]

5. The capacitance of all the capacitors shown in Fig. 5.88 are as below :
$C_1 = C_5 = 3$ μF, $C_2 = 5$ μF, $C_3 = C_4 = C_6 = 4$ μF and $C_7 = 2$ μF.
(*a*) What is the equivalent capacitance between the points A and B ? (*b*) If the charge on 5 μF capacitor is 120 μC, what is the potential difference between the two points A and B ? [**Ans.** (*a*) 5 μF ; (*b*) 96 V]

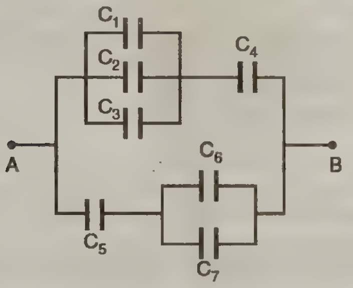

Fig. 5.88

36. Two capacitors of capacitances 2 μF and 4 μF are separately charged to potentials 100 V and 75 V respectively. What are the charges carried by each ? What would be the value of the potential, when they are connected together in parallel and what would be charges on them after contact ?
[**Ans.** 200 μC, 300 μC, 83·33 V ; 166·67 μC, 333·33 μC]

37. Two capacitors A and B of capacitances 4 μF and 2 μF respectively are connected in series with a battery of e.m.f. 100 V. The connections are broken and the like terminals of the capacitors are then joined. Find the final charge on each capacitor. [**Ans.** 177·8 μC, 88·9 μC]

38. A capacitor of 3 μF is charged to a potential difference of 300 V and a capacitor of 2 μF to 200 V. After charging the capacitors, their plates charged with unlike charges are connected. What quantity of electricity will be transferred during connection and from what capacitor will this take place ? [**Ans.** 6×10^{-4} C from capacitor of 3 μF]

39. A conductor charged to a potential of 40 V is connected to an uncharged conductor of 10 F capacitance. The common potential developed is 25 V. Calculate the capacitance of the first conductor. [**Ans.** 16·67 F]

40. A conductor has a charge of 0·5 μC and at potential of 20 V. Another uncharged conductor, whose capacity is 0·015 μF is momentarily connected to the first and then separated. Calculate the charges carried by each after contact and what is the value of the common potential.
[**Ans.** 0·3125 μC, 0·1875 μC ; 12·5 V]

41. An air capacitor has an area of 1000 cm^2 and the plates being 4 mm apart. It is connected in series with another capacitor having a plate area of 20 cm^2, the plates being separated by a dielectric 0·1 mm thick having dielectric constant of 2·5. If the potential difference across the second capacitor is 100 V, find the voltage applied across the series combination. [**Ans.** 300 V]

Type F. On Energy stored in a capacitor

42. Two insulated spherical conductors of radii 5·0 cm and 10·0 cm are charged to potentials of 600 V and 300 V respectively. Calculate the total energy of the system. Also calculate the energy after the spheres have been connected by a fine wire. [**Ans.** $1{\cdot}5 \times 10^{-6}$ J, $1{\cdot}33 \times 10^{-6}$ J]

43. A capacitor charged from a 50 V d.c. supply is found to have a charge of 10 μC. What is the capacitance of the capacitor and how much energy is stored in it ?
(*I.S.C.E. 1993*) [**Ans.** 0·2 μF ; $2{\cdot}5 \times 10^{-4}$ J]

44. A capacitor with a capacitance of 50 μF is connected to a battery of 10 V. Find the charge on it in coulomb and its energy in joule. [**Ans.** 500 μC, $2{\cdot}5 \times 10^{-3}$ J]

45. A parallel plate capacitor of 300 μF is charged to 200 V. If the distance between its plates is halved, what will be the potential between the plates and what will be the change in energy stored in it ? (*P.S.S.C.E. 1999*)

[**Ans.** 100 V, 3 J (decrease)]

46. The plates of a parallel plate capacitor are 50 cm^2 and one mm apart. (*a*) What is its capacitance ? (*b*) When it is connected to a 45 V battery, what is the charge on either plate and the energy stored in it ? (*c*) What is the electric field between the plates ?

[**Ans.** (*a*) 44·27 pF ; (*b*) $1{\cdot}99 \times 10^{-9}$ C ; $4{\cdot}48 \times 10^{-8}$ J ; (*c*) $4{\cdot}5 \times 10^{4}$ V m^{-1}]

47. A 400 pF capacitor is charged by a 100 V battery. How much electrostatic energy is stored by the capacitor ? The capacitor is disconnected from the battery and connected to another 400 pF capacitor. What is the electrostatic energy stored by the system ? (*H.S.S.C.E. 1999 S ; P.S.S.C.E. 1991*)

[**Ans.** $2{\cdot}0 \times 10^{-6}$ J, 10^{-6} J]

48. A capacitor carrying a charge equal to 2 μC up to a potential 100 V is put into contact with another capacitor carrying a charge of 1·5 μC up to a potential of 60 V. What is the resulting potential, the charge carried by each, the total energy before and after connection ?

[**Ans.** 77·78 V ; $1{\cdot}56 \times 10^{-6}$ C ; $1{\cdot}94 \times 10^{-6}$ C ; $1{\cdot}45 \times 10^{-4}$ J ; $1{\cdot}36 \times 10^{-4}$ J]

49. Two capacitors are in parallel and the energy stored is 45 J, when the combination is raised to a potential of 3000 V. With the same two capacitors in series, the energy is 4·05 J for the same potential. What are their capacitances ? [**Ans.** 9 μF, 1 μF]

Type G. On Loss of energy on sharing charges

50. A variable capacitor is kept connected to a 10 V battery. If the capacitance of the capacitor is changed from 7 μF to 3 μF, what is the change in the energy ? What happens to this energy ? (*I.S.C.E. 1996*)

[**Ans.** 2×10^{-4} J (decreases), lost as heat and electromagnetic radiation]

51. A capacitor of capacitance 6 μF is charged to a potential equal to 150 V. Its potential falls to 90 V, when another capacitor is connected to it. Find the capacitance of the second capacitor and the amount of energy lost due to the connection. [**Ans.** 4 μF ; 0·027 J]

52. A 5 μF capacitor is charged by a 220 V supply. It is then disconnected from the supply and is connected to another uncharged 2·5 μF capacitor. How much electrostatic energy of the first capacitor is lost in the form of heat and electromagnetic radiation ? (*P.S.S.C.E. 1998 S*)

[**Ans.** 0·04 J]

53. A 12 mF capacitor is charged by a 200 V supply. It is then disconnected from the supply and is connected to another uncharged 8 mF capacitor. How much electrostatic energy of first capacitor is lost in the form of heat and electromagnetic radiation ? [**Ans.** 96 J]

54. A 600 pF capacitor is charged by a 200 V supply. It is then disconnected from the supply and is connected to another uncharged 600 pF capacitor. How much electrostatic energy is lost in the process ? (*Text Problem*)

[**Ans.** 6×10^{-6} J]

55. Two capacitors of 25 μF and 100 μF are connected in series to a source of 120 V. Keeping their charges unchanged, they are separated and connected in parallel to each other. Find out (*a*) potential difference between the plates of each capacitor and (*b*) energy loss in the process.

[**Ans.** 38·4 V ; 0·052 J]

Type H. On Effect of dielectric

56. An air capacitor of capacitance 2 μF is charged to a potential 200 V. What is the energy stored in it ? If a medium of dielectric constant 2 is inserted between its plates and the potential is raised again to the same valu
what is the amount of energy, it would store ?

[**Ans.** 0·04 J ; 0·08

57. A parallel plate capacitor has capacitance 20 μF. A potent
difference of 220 V is applied across it. Calculate the char
on the plates and energy stored in capacitor. If a dielect
slab of dielectric constant 55 is introduced between
plates, calculate the new value of potential difference a
the energy stored.

[**Ans.** $4{\cdot}4 \times 10^{-3}$ C, 0·0484 J ; 4 V, $8{\cdot}8 \times 10^{-3}$

58. When a slab of insulating material 4 mm thick
introduced between the plates of a parallel plate capacit
it is found that the distance between the plates has to
increased by 3·2 mm to restore the capacitance to
original value. Calculate dielectric constant of the materi

[**Ans.**

59. A parallel plate capacitor with plate separation 5 mm
charged by a battery. It is found that on introducting a mi
sheet 2 mm thick, while keeping the battery connectio
intact, the capacitor draws 25% more charge from t
battery than before. Find the dielectric constant of mic

[**Ans.**

60. An air parallel plate capacitor having plates of area
6×10^{-3} m^2 and plate separation 3 mm is connected t
200 V supply. Calculate charge on each plate of t
capacitor. Explain what would happen, when a 3 mm thi
mica sheet (K = 8) is inserted between the plates (*a*) wh
supply voltage remains connected and (*b*) after the supp
is disconnected.

[**Ans.** $3{\cdot}54 \times 10^{-9}$ C ; (*a*) $2{\cdot}83 \times 10^{-8}$ C ; (*b*) $3{\cdot}54 \times 10^{-9}$

61. A parallel plate capacitor has a capacitance of 2 μF. A sl
of dielectric constant 5 is inserted between the plates a
the capacitor is charged to 100 V and then isolated. (*a*) Wh
is the new potential difference, if the dielectric slab
removed ? (*b*) How much work is required to remove t
dielectric slab ? [**Ans.** (*a*) 500 V ; (*b*) 0 · 2

Type I. On Van de Graaff generator

62. In a Van de Graaff generator, the spherical metal shell
to be kept at 18×10^{5} V. The dielectric strength of the g
surrounding the metal shell is $4 \cdot 5 \times 10^{7}$ V m^{-1}. What
the minimum radius of the spherical shell required ?

[**Ans.** 4 c

63. A spark passes in air, when the potential gradient at t
surface of a charged conductor is 3×10^{6} V m^{-1}. What m
be the radius of an insulated metal sphere, which can
raised to a potential of 3×10^{6} V, before sparking into t
air ? What will be the energy stored immediately bef
sparking occurs ? (*Text Problem*) [**Ans.** 1 m ; 500

MISCELLANEOUS PROBLEMS

64. A capacitor is made of a flat plate of area A and a seco
plate having a stair-like structure. The height of first st
of the stair is *d*, while those of subsequent steps is *b* [F
5.89]. If all the steps are of same width, calculate t
capacitance of the structure.

$$\left[\textbf{Ans. } \frac{\varepsilon_0 A (3d^2 + 6bd + 2b^2}{3d(d+b)(d+2b)}\right.$$

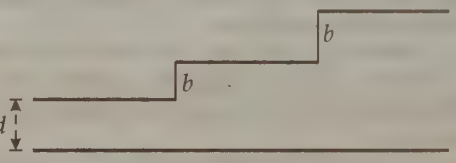

Fig. 5.89

65. Find the capacitance of a system of three parallel plates each of area A metre^2 separated by distances d_1 and d_2 metre respectively. The space between them is filled with dielectrics of relative dielectric constants ε_1 and ε_2. The dielectric constant of free space is ε_0. *(Roorkee 1987)*

$$\left[\textbf{Ans. } \frac{\varepsilon_0\,\varepsilon_1\,\varepsilon_2\,A}{d_1\,\varepsilon_2+d_2\,\varepsilon_1}\right]$$

66. A parallel plate capacitor is constructed using three different dielectric materials as shown in Fig. 5.90. The parallel plates across which a potential difference is applied are of area A = 1 cm^2 and are separated by a distance d = 2 mm. If $K_1 = 4$, $K_2 = 6$ and $K_3 = 2$, find capacitance across points A and B. **[Ans. 1·56 pF]**

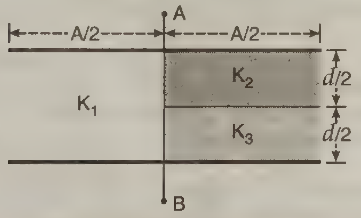

Fig. 5.90

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Charge on each conductor,

$$q = N\,e = 6{\cdot}02\times10^{23}\times1{\cdot}6\times10^{-19}\text{ C}$$

Now, $$C=\frac{q}{V}=\frac{6\cdot02\times10^{23}\times1\cdot6\times10^{-19}}{10^6}=\mathbf{9{\cdot}63\times10^{-2}\ F}$$

2. Let q be charge on the spherical conductor and r be its radius. Then,

$$\frac{q}{4\pi r^2}=0\cdot07\text{ C m}^{-2} \qquad ...(i)$$

When charge is increased by 4·4 C, we have

$$\frac{q+4\cdot4}{4\pi r^2}=0\cdot084\text{ C m}^{-2} \qquad ...(ii)$$

From equation (*i*) and (*ii*), we get

$$\frac{q+4\cdot4}{q}=\frac{0\cdot084}{0\cdot07} \quad\text{or}\quad q=\mathbf{22\ C}$$

From equation (*i*), we have

$$r=\sqrt{\frac{q}{4\pi\times0\cdot07}}=\sqrt{\frac{22}{4\pi\times0\cdot07}}=5\text{ cm}=0\cdot05\text{ m}$$

Therefore, capacitance of spherical conductor,

$$C=4\pi\,\varepsilon_0\,r=\frac{0\cdot05}{9\times10^9}=\mathbf{5{\cdot}56\times10^{-12}\ F}$$

3. Proceed as in solved problem no. 5.03.

4. By proceeding as in solved problem no. 5.03, find the radius of bigger drop. It will be found that

$$R=3\,r=3\times3=9\text{ mm}=9\times10^{-3}\text{ m}$$

$$\therefore\quad C=4\pi\,\varepsilon_0\,R\ \frac{9\times10^{-3}}{9\times10^9}=\mathbf{10^{-12}\ F}$$

5. Let q be charge on each small drop and r be its radius. Then, capacitance and potential of each small drop,

$$C=4\pi\,\varepsilon_0\,r \quad\text{and}\quad V=\frac{1}{4\pi\,\varepsilon_0}\cdot\frac{q}{r}$$

Let R is radius of the big drop formed. Then,

$$\frac{4}{3}\pi\,r^3\times N=\frac{4}{3}\pi\,R^3 \quad\text{or}\quad R=N^{1/3}\,r$$

Charge on big drop, $q'=N\,q$ or $\dfrac{q'}{q}=N$

Capacitance of big drop,

$$C'=4\pi\,\varepsilon_0\,R=4\pi\,\varepsilon_0\,N^{1/3}\,r=N^{1/3}\,C$$

or $$\frac{C'}{C}=\mathbf{N^{1/3}}$$

Potential of big drop, $$V'=\frac{1}{4\pi\,\varepsilon_0}\cdot\frac{q'}{R}$$

$$=\frac{1}{4\pi\,\varepsilon_0}\cdot\frac{N\,q}{N^{1/3}r}=N^{2/3}\times\frac{1}{4\pi\,\varepsilon_0}\cdot\frac{q}{r}$$

or $V'=N^{2/3}\,V$ or $\dfrac{V'}{V}=\mathbf{N^{2/3}}$

6. Here, $r_1=5$ cm $=0{\cdot}05$ m ; $r_2=10$ cm $=0{\cdot}1$ m,

$$q_1=q_2=75\ \mu C=75\times10^{-6}\text{ C}$$

(*a*) Now, $C_1=4\pi\,\varepsilon_0\,r_1=4\pi\,\varepsilon_0\times0{\cdot}05$

and $C_2=4\pi\,\varepsilon_0\,r_2=4\pi\,\varepsilon_0\times0{\cdot}1$

Common potential,

$$V=\frac{q_1+q_2}{C_1+C_2}=\frac{75\times10^{-6}+75\times10^{-6}}{4\pi\,\varepsilon_0\times0\cdot05+4\pi\,\varepsilon_0\times0\cdot1}$$

$$=\frac{9\times10^9\times150\times10^{-6}}{0\cdot15}$$

or $$V=\mathbf{9\times10^6\ V}$$

(*b*) Now, $q_1'=C_1V=4\pi\,\varepsilon_0\times0{\cdot}05\times9\times10^6$

$$=50\times10^{-6}\text{ C}=50\ \mu C$$

Therefore, charge transferred $=q_1-q_1'=75-50=\mathbf{25\ \mu C}$

7. Capacitance of spherical conductor, $C=4\pi\,\varepsilon_0\,R$

or $$C=4\pi\,\varepsilon_0\times0{\cdot}5 \qquad ...(i)$$

Let d be distance between the two plates of air capacitor.

Area of each plate, $A=0{\cdot}2\times0{\cdot}1=0{\cdot}02\text{ m}^2$

$$\therefore\quad C=\frac{\varepsilon_0\,A}{d}=\frac{\varepsilon_0\times0\cdot02}{d} \qquad ...(ii)$$

From equations (*i*) and (*ii*), we have

$$\frac{\varepsilon_0\times0\cdot02}{d}=4\pi\,\varepsilon_0\times0\cdot5$$

or $$d=\frac{0\cdot02}{4\pi\times0\cdot5}=\mathbf{3{\cdot}183\times10^{-3}\ m}$$

8. Proceed as in problem no. 7.

9. Proceed as in problem no. 7.

10. $$C=\frac{\varepsilon_0\,A}{d}=\frac{8\cdot854\times10^{-12}\times6\times10^{-3}}{3\times10^{-3}}=1\cdot77\times10^{-11}\text{F}$$

Now, $q=C\,V=1{\cdot}77\times10^{-11}\times100=\mathbf{1{\cdot}77\times10^{-9}\ V}$

11. Now, $C=\dfrac{\varepsilon_0\,K\,A}{d}$

Here, $K=4$, $A=0{\cdot}055\times0{\cdot}04\text{ m}^2$,

$d=0{\cdot}7$ mm $=0{\cdot}7\times10^{-3}$ m

$$\therefore\quad C=\frac{8\cdot854\times10^{-12}\times4\times0\cdot055\times0\cdot04}{0\cdot7\times10^{-3}}$$

$$=\mathbf{1{\cdot}1\times10^{-10}\ F}$$

12. $$C=\frac{\varepsilon_0\,A}{d}=\frac{8\cdot854\times10^{-12}\times0\cdot02}{1\times10^{-3}}=1\cdot77\times10^{-10}\text{ F}$$

Now, $$V=\frac{q}{C}=\frac{10^{-9}}{1\cdot77\times10^{-10}}=\mathbf{5{\cdot}65\ V}$$

On increasing the separation :

$$C=\frac{\varepsilon_0\,A}{d}=\frac{8\cdot854\times10^{-12}\times0\cdot02}{2\times10^{-3}}=8\cdot854\times10^{-11}\text{ F}$$

Now, $V = \frac{q}{C} = \frac{10^{-9}}{8\cdot854\times10^{-11}} = \mathbf{11{\cdot}3\ V}$

13. $C = 4\pi\varepsilon_0 K\cdot\frac{ab}{b-a} = \frac{1}{9\times10^{-9}}\times20\times\frac{0\cdot2\times0\cdot3}{0\cdot3-0\cdot2}$

$= 1{\cdot}333\times10^{-9}\ \text{F} = \mathbf{1333\ pF}$

14. Proceed as in problem no. 13.
15. Proceed as in solved problem no. 5.08.
16. Capacitance per metre,

$$C = \frac{2\pi\varepsilon_0 K}{2\cdot303\log_{10}\frac{b}{a}} = \frac{2\pi\times8\cdot854\times10^{-12}\times12}{2\cdot303\times\log_{10}\frac{0\cdot6\times10^{-3}}{0\cdot1\times10^{-3}}}$$

$= \mathbf{3{\cdot}725\times10^{-10}\ F\ m^{-1}}$

17. Now, $C = \frac{2\pi\varepsilon_0 K l}{2\cdot303\log_{10}\frac{b}{a}}$

Here, $K = 7$, $l = 1$ km $= 10^3$ m, $a = \frac{3}{2} = \mathbf{1{\cdot}5\ mm}$

$b = a$ + thickness of dielectric $= 1{\cdot}5 + 3 = 4{\cdot}5$ mm

$$\therefore\quad C = \frac{2\pi\times8\cdot854\times10^{-12}\times7\times10^3}{2\cdot303\log_{10}\frac{4\cdot5\times10^{-3}}{1\cdot5\times10^{-3}}} = 0{\cdot}354\times10^{-6}\ \text{F}$$

$= \mathbf{0{\cdot}354\ \mu F}$

18. $C_1 = 4\pi\varepsilon_0 r_1 = \frac{2\times10^{-2}}{9\times10^9} = 2\cdot22\times10^{-12}\ \text{F} = 2\cdot22\ \text{pF}$

$C_2 = 4\pi\varepsilon_0 r_2 = \frac{7\times10^{-2}}{9\times10^9} = 7\cdot78\times10^{-12}\ \text{F} = 7\cdot78\ \text{pF}$

When the two spheres are connected in series :

$C = \frac{C_1C_2}{C_1+C_2} = \frac{2\cdot22\times7\cdot78}{2\cdot22+7\cdot78} = \mathbf{1{\cdot}73\ pF}$

When the two spheres are connected in parallel :

$C' = C_1 + C_2 = 2{\cdot}22 + 7{\cdot}78 = \mathbf{10{\cdot}0\ pF}$

19. Proceed as in SAQ 5.11.
20. Let the capacitances of the three capacitors be C, 2 C and 3 C.

When connected in parallel :

$C' = C + 2C + 3C = 6C$

When connected in series :

$\frac{1}{C''} = \frac{1}{C} + \frac{1}{2C} + \frac{1}{3C}$ or $C'' = \frac{6C}{11}$

According to the statement of the problem,

$6C = \frac{6C}{11} + \frac{60}{11}$ or $C = 1\ \mu F$

Therefore, capacitances of the three capacitors are **1 μF, 2 μF**, and **3 μF**.

21. Proceed as in solved problem no. 5.12.
22. The capacitors are connected as shown in Fig. 5.91.

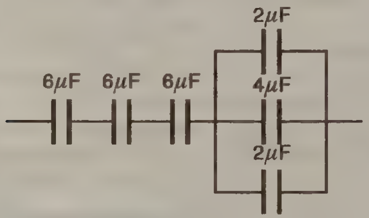

Fig. 5.91

The capacitance of the parallel combination of 2 μF, 4 μF and 2 μF capacitors,

$C' = 2 + 4 + 2 = 8\ \mu F$

The capacitance of the whole combination is given by

$$\frac{1}{C} = \frac{1}{6}+\frac{1}{6}+\frac{1}{6}+\frac{1}{C'} = \frac{1}{6}+\frac{1}{6}+\frac{1}{6}+\frac{1}{8} = \frac{15}{24}$$

or $C = \frac{24}{15} = \mathbf{1{\cdot}6\ \mu F}$

23. The capacitance of parallel combination of three capacito each of 20 μF,

$C' = 20 + 20 + 20 = 60\ \mu F$

Now, $\frac{1}{C}+\frac{1}{C'} = \frac{1}{30}$ or $\frac{1}{C} = \frac{1}{30} - \frac{1}{60} = \frac{1}{60}$ or $C = 60$

24. Let C′ be capacitance of the series combination of C_1 a C_2. Then,

$C' = \frac{C_1C_2}{C_1+C_2}$.

Therefore, equivalent capacitance of the system betwe points X and Y,

$C_{equi} = C' + C + C' = C + 2C' = C + \frac{2C_1C_2}{C_1+C_2}$

25. Refer to SAQ 5.14 : The three capacitors connect between points A and B are in parallel. If C′ is capacitance of their combination, then

$C' = 5 + 10 + 15 = 30\ \mu F$

Now, capacitor C′ and 30 μF capacitor are in seri Therefore, equivalent capacitance between points X anc

$C = \frac{C'\times30}{C'+30} = \frac{30\times30}{30+30} = \mathbf{15\ \mu F}$

26. By proceeding as in solved problem 5.19, find equivalent capacitance C′ between points A and B of arrangement. It can be obtained that

$C' = 5\ \mu F$

Now, capacitor C′ and the left out 5 μF capacitor are series. Therefore, equivalent capacitance between poi X and Y,

$C = \frac{C'\times5}{C'+5} = \frac{5\times5}{5+5} = \mathbf{2{\cdot}5\ \mu F}$

27. The two capacitors are connected in parallel.

$\therefore\quad C = 2{\cdot}2 + 2{\cdot}2 = 4{\cdot}4\ \mu F$

Now, $q = CV = 4{\cdot}4\times10 = \mathbf{44\ \mu C}$

28. It follows that the two 2 μF capacitors connected at extreme left end of the network are in series. The equival capacitance of these two capacitors,

$C_s = \frac{2\times2}{2+2} = 1\ \mu F$

This equivalent capacitor C_s and the next capacitor of 1 are in parallel. Therefore, equivalent capacitance of C_s a this 1 μF capacitor,

$C_p = 1 + 1 = 2\ \mu F$

Now, the series combination of C_p and the next 2 μ connected in parallel to the next 1 μF capacitor. If continue finding equivalent capacitance in such ste finally the series combination of two 2 μF capacitors be left. Therefore, equivalent capacitance of the netwo

$C = \frac{2\times2}{2+2} = \mathbf{1\ \mu F}$

29. Let q_1 and q_2 be charges on the two capacitors.

Then, $q_1 = C_1V = 0{\cdot}5\times10^{-6}\times100 = 50\times10^{-6}\ \text{C} = \mathbf{50\ \mu}$

and $q_2 = C_2V = 0{\cdot}75\times10^{-6}\times100 = 75\times10^{-6} = \mathbf{75\ \mu}$

Therefore, charge taken from the source,

$q = q_1 + q_2 = 50 + 75 = \mathbf{125\ \mu C}$

30. (*i*) Now, $\frac{1}{C_s} = \frac{1}{8}+\frac{1}{12}+\frac{1}{24} = \frac{3+2+1}{24} = \frac{6}{24}$

or $C_s = \mathbf{4\ \mu F}$

(ii) Also, $C_p = 8 + 12 + 24 = \mathbf{44\ \mu F}$

When capacitors are connected in series, charge on each capacitor is same. Let q be charge on each capacitor. If V_1, V_2 and V_3 are potential differences across these capacitors, then

$$V_1 + V_2 + V_3 = 100$$

or $$\frac{q}{8\times10^{-6}} + \frac{q}{12\times10^{-6}} + \frac{q}{24\times10^{-6}} = 100$$

or $$\frac{q}{24\times10^{-6}}(3+2+1) = 100 \quad \text{or} \quad q = \mathbf{4\times10^{-4}\ C}$$

Note. Charge on each capacitor of the series combination,

$$q = C_s \times V = 4\times10^{-6}\times100 = \mathbf{4\times10^{-4}\ C}$$

31. *(i)* By proceeding as in solved problem no. 5.34, it can be obtained that equivalent capacitance,

$$C = \frac{200}{3} = \mathbf{66{\cdot}67\ pF}$$

(ii) Now, $q = C\,V = \frac{200}{3}\times10^{-12}\times300 = \mathbf{2\times10^{-8}\ C}$

32. *(a)* The capacitance of series combination of C_1, C_2 and C_3 is given by

$$\frac{1}{C'} = \frac{1}{10} + \frac{1}{10} + \frac{1}{10} = \frac{3}{10} \quad \text{or} \quad C' = \frac{10}{3} = 3{\cdot}33\ \mu F$$

Therefore, equivalent capacitance of the combination between points A and D,

$$C = C' + C_4 = 3{\cdot}33 + 10 = \mathbf{13{\cdot}33\ \mu F}$$

(b) Let q_1, q_2, q_3 and q_4 be charge on capacitors C_1, C_2, C_3 and C_4 respectively.

As, C_1, C_2 and C_3 are in series,

$$q_1 = q_2 = q_3 = C' \times V = \frac{10}{3}\times10^{-6}\times500$$
$$= \mathbf{1{\cdot}67\times10^{-3}\ C}$$

Also, $q_4 = C_4 \times V = 10\times10^{-6}\times500 = \mathbf{5{\cdot}0\times10^{-3}\ C}$

33. Equivalent capacitance of parallel combination of C_2 and C_3,

$$C_{23} = C_2 + C_3 = 3 + 5 = 8\ \mu F$$

Equivalent capacitance of the whole network,

$$C = \frac{C_1 \times C_{23}}{C_1 + C_{23}} = \frac{2\times8}{2+8} = 1{\cdot}6\ \mu F$$

The charge acquired by the network,

$$q = C\,V = 1{\cdot}6\times10^{-6}\times100 = 1{\cdot}6\times10^{-4}\ C$$

Since C_1 and C_{23} are in series, charge on each of them is same as on the network *i.e.* equal to $1{\cdot}6\times10^{-4}$ C.

Potential difference across C_1,

$$V_1 = \frac{q}{C_1} = \frac{1{\cdot}6\times10^{-4}}{2\times10^{-6}} = \mathbf{80\ V}$$

As C_2 and C_3 are in parallel,

$$V_2 = V_3 = \frac{q}{C_{23}} = \frac{1{\cdot}6\times10^{-4}}{8\times10^{-6}} = \mathbf{20\ V}$$

34. *(i)* $q_1 = C_1\,V = 10\times10^{-6}\times250 = \mathbf{2500\ \mu C}$,

$q_2 = C_2\,V = 50\times10^{-6}\times250 = \mathbf{12500\ \mu C}$

and $q_3 = C_3\,V = 25\times10^{-6}\times250 = \mathbf{6250\ \mu C}$

(ii) $C_p = C_1 + C_2 + C_3 = 10 + 50 + 25 = \mathbf{85\ \mu F}$

(iii) $$\frac{1}{C_s} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} = \frac{1}{10} + \frac{1}{50} + \frac{1}{25} = \frac{8}{50}$$

or $$C_s = \frac{50}{8} = 6{\cdot}25\ \mu F$$

Charge on each capacitor is equal to charge on the series combination. Therefore,

$$q_1 = q_2 = q_3 = C_s \times V = 6{\cdot}25\times10^{-6}\times250$$
$$= 1{\cdot}5625\times10^{-3}\ C$$

$$\therefore \quad V_1 = \frac{q_1}{C_1} = \frac{1{\cdot}5625\times10^{-3}}{10\times10^{-6}} = \mathbf{156{\cdot}25\ V},$$

$$V_2 = \frac{q_2}{C_2} = \frac{1{\cdot}5625\times10^{-3}}{50\times10^{-6}} = \mathbf{31{\cdot}25\ V}$$

and $$V_3 = \frac{q_3}{C_3} = \frac{1{\cdot}5625\times10^{-3}}{25\times10^{-6}} = \mathbf{62{\cdot}5\ V}$$

35. *(a)* Equivalent capacitance of parallel combination of C_1, C_2 and C_3,

$$C_{123} = C_1 + C_2 + C_3 = 3 + 5 + 4 = 12\ \mu F$$

Equivalent capacitance of series combination of C_{123} and C_4,

$$C' = \frac{C_{123}\times C_4}{C_{123} + C_4} = \frac{12\times4}{12+4} = 3\ \mu F$$

Equivalent capacitance of parallel combination of C_6 and C_7,

$$C_{67} = C_6 + C_7 = 4 + 2 = 6\ \mu F$$

Equivalent capacitance of series combination of C_5 and C_{67},

$$C'' = \frac{C_5 \times C_{67}}{C_5 + C_{67}} = \frac{3\times6}{3+6} = 2\ \mu F$$

Therefore, capacitance of network between points A and B,

$$C = C' + C'' = 3 + 2 = \mathbf{5\ \mu F}$$

(b) Charge on 5 μF capacitor *i.e.* C_2,

$$q_2 = 120\ \mu C = 120\times10^{-6}\ C$$

$$\therefore \quad V_2 = \frac{q_2}{C_2} = \frac{120\times10^{-6}}{5\times10^{-6}} = 24\ V$$

Therefore, charge on parallel combination of C_1, C_2 and C_3,

$$q_{123} = C_{123} \times V_2 = 12\times10^{-6}\times24 = 2{\cdot}88\times10^{-4}\ C$$

Since C_{123} and C_4 are in series,

$$q_4 = q_{123} = 2{\cdot}88\times10^{-4}\ C$$

and $$V_4 = \frac{q_4}{C_4} = \frac{2{\cdot}88\times10^{-4}}{4\times10^{-6}} = 72\ V$$

Hence, potential difference between points A and B,

$$V = V_2 + V_4 = 24 + 72 = \mathbf{96\ V}$$

36. Here, $C_1 = 2\ \mu F$; $C_2 = 4\ \mu F$; $V_1 = 100$ V ; $V_2 = 75$ V

$$q_1 = C_1\,V_1 = 2\times100 = \mathbf{200\ \mu C}$$

and $$q_2 = C_2\,V_2 = 4\times75 = \mathbf{300\ \mu C}$$

When capacitors are connected in parallel :

Total capacitance, $C = C_1 + C_2 = 2 + 4 = 6\ \mu C$

Total charge, $q = q_1 + q_2 = 200 + 300 = 500\ \mu C$

Therefore, potential difference across the combination (or individual capacitor),

$$V = \frac{q}{C} = \frac{500}{6} = \mathbf{83{\cdot}33\ V}$$

Now, $$q_1' = C_1\,V = 2\times\frac{500}{6} = \mathbf{166{\cdot}67\ \mu C}$$

and $$q_2' = C_2\,V = 4\times\frac{500}{6} = \mathbf{333{\cdot}33\ \mu C}$$

37. ***When capacitors are connected in series with a battery of 100 V :***

Total capacitance, $$C = \frac{C_1\,C_2}{C_1 + C_2} = \frac{4\times2}{4+2} = \frac{4}{3}\ \mu F$$

Charge on capacitors C_1 and C_2,

$$q_1 = q_2 = C\,V = \frac{4}{3}\times100 = \frac{400}{3}\ \mu C$$

When charged capacitors are connected in parallel :

Total charge on the two capacitors,

$$q' = q_1 + q_2 = \frac{400}{3} + \frac{400}{3} = \frac{800}{3}\ \mu C$$

Total capacitance of the combination,

$C' = 4 + 2 = 6\ \mu F$

Common potential of the two capacitors,

$$V = \frac{q'}{C'} = \frac{800/3}{6} = \frac{400}{9}\ V$$

$\therefore \quad q_1' = C_1 V = 4 \times \frac{400}{9} = \mathbf{177{\cdot}8\ \mu C}$

and $\quad q_2' = C_2 V = 2 \times \frac{400}{9} = \mathbf{88{\cdot}9\ \mu C}$

38. Here, $C_1 = 3\ \mu F$; $V_1 = 300$ V ; $C_2 = 2\ \mu F$; $V_2 = 200$ V

Now, $q_1 = C_1 V_1 = 3 \times 300 = 900\ \mu C$

and $\quad q_2 = C_2 V_2 = 2 \times 200 = 400\ \mu C$

When plates of two capacitors charged with unlike charges are connected :

Total charge on the combination,

$q = 900 + (-400) = 500\ \mu C$

Total capacitance of the combination,

$C = C_1 + C_2 = 3 + 2 = 5\ \mu F$

Common potential, $V = \frac{q}{C} = \frac{500}{5} = 100$ V

$\therefore \quad q_1' = 3 \times 100 = 300\ \mu C$

Hence, charge transferred from capacitor C_1,

$q_1 - q_1' = 900 - 300 = 600\ \mu C = \mathbf{6 \times 10^{-4}\ C}$

39. Let C_1 be capacitance of the first conductor,

Here, $V_1 = 40$ V ; $C_2 = 10$ F, $q_2 = 0$

Now, $q_1 = C_1 V_1 = C_1 \times 40$

Common potential,

$$V = \frac{q_1 + q_2}{C_1 + C_2} = \frac{C_1 \times 40 + 0}{C_1 + 10} = \frac{C_1 \times 40}{C_1 + 10}$$

Thus, $\frac{C_1 \times 40}{C_1 + 10} = 25$ or $C_1 = \mathbf{16{\cdot}67\ F}$

40. Here, $q_1 = 0{\cdot}5\ \mu C$, $V_1 = 20$ V, $C_2 = 0{\cdot}015\ \mu F$, $q_2 = 0$

Now, $C_1 = \frac{q_1}{V_1} = \frac{0{\cdot}5}{20} = 0{\cdot}025\ \mu F$

When capacitor C_2 is connected momentarily to C_1 (in parallel),

total capacitance, $C = C_1 + C_2 = 0{\cdot}025 + 0{\cdot}015 = 0{\cdot}04\ \mu F$

total charge, $\quad q = q_1 + q_2 = 0{\cdot}5 + 0 = 0{\cdot}5\ \mu C$

common potential, $V = \frac{q}{C} = \frac{0{\cdot}5}{0{\cdot}04} = \mathbf{12{\cdot}5\ V}$

Now, $q_1' = C_1 V = 0{\cdot}025 \times 12{\cdot}5 = \mathbf{0{\cdot}3125\ \mu C}$

and $\quad q_2' = C_2 V = 0{\cdot}015 \times 12{\cdot}5 = \mathbf{0{\cdot}1875\ \mu C}$

41. Here, $A_1 = 1000\ cm^2 = 0{\cdot}1\ m^2$; $d_1 = 4$ mm $= 4 \times 10^{-3}$ m ;

$K_1 = 1$

$A_2 = 20\ cm^2 = 20 \times 10^{-4}\ m^2$; $d_2 = 0{\cdot}1$ mm $= 10^{-4}$ m ;

$K_2 = 2{\cdot}5$

$$\therefore \quad C_1 = \frac{\varepsilon_0 K_1 A_1}{d_1} = \frac{8{\cdot}854 \times 10^{-12} \times 1 \times 0{\cdot}1}{4 \times 10^{-3}}$$

$$= 221{\cdot}35 \times 10^{-12}\ F$$

$$\text{and} \quad C_2 = \frac{\varepsilon_0 K_2 A_2}{d_2} = \frac{8{\cdot}854 \times 10^{-12} \times 2{\cdot}5 \times 20 \times 10^{-4}}{10^{-4}}$$

$$= 442{\cdot}7 \times 10^{-12}\ F$$

Now, potential difference across second capacitor,

$V_2 = 100$ V

$\therefore \quad q_2 = C_2 V_2 = 442{\cdot}7 \times 10^{-12} \times 100 = 442{\cdot}7 \times 10^{-10}$ C

As the two capacitors are in series, charge on first capacitor,

$q_1 = q_2 = 442{\cdot}7 \times 10^{-10}$ C

Therefore, potential difference across first capacitor,

$$V_1 = \frac{q_1}{C_1} = \frac{442{\cdot}7 \times 10^{-10}}{221{\cdot}35 \times 10^{-12}} = 200\ V$$

Hence, potential difference across series combinatio

$V = V_1 + V_2 = 200 + 100 = \mathbf{300\ V}$

42. Here, $r_1 = 5{\cdot}0$ cm $= 0{\cdot}05$ m, $r_2 = 10{\cdot}0$ cm $= 0{\cdot}1$ m ;

$V_1 = 600$ V ; $V_2 = 300$ V

Now, $C_1 = 4\pi\varepsilon_0 r_1 = \frac{0{\cdot}05}{9 \times 10^9} = \frac{5}{9} \times 10^{-11}$ F ;

$$C_2 = 4\pi\varepsilon_0 r_2 = \frac{0{\cdot}1}{9 \times 10^9} = \frac{10}{9} \times 10^{-11}\ F$$

Now, total energy, $U = \frac{1}{2} C_1 V_1^2 + \frac{1}{2} C_2 V_2^2$

$$= \frac{1}{2} \times \frac{5}{9} \times 10^{-11} \times (600)^2 + \frac{1}{2} \times \frac{10}{9} \times 10^{11} \times (3$$

$$= 10^{-6} + 0{\cdot}5 \times 10^{-6} = \mathbf{1{\cdot}5 \times 10^{-6}\ J}$$

On connecting with wire :

$C = C_1 + C_2 = \frac{5}{9} \times 10^{-11} + \frac{10}{9} \times 10^{-11} = \frac{5}{3} \times 10^{-11}$ F

Total charge, $q = q_1 + q_2 = C_1 V_1 + C_2 V_2$

$$= \frac{5}{9} \times 10^{-11} \times 600 + \frac{10}{9} \times 10^{-11} \times 300 = \frac{20}{3} \times 10$$

$$\text{Total energy,} \quad U' = \frac{1}{2}\frac{q^2}{C} = \frac{1}{2} \times \frac{(\frac{20}{3} \times 10^{-9})^2}{\frac{5}{3} \times 10^{-11}}$$

$$= \mathbf{1{\cdot}33 \times 10^{-6}\ J}$$

43. Here, V = 50 V and $q = 10\ \mu C$

$\therefore \quad C = \frac{q}{V} = \frac{10}{50} = \mathbf{0{\cdot}2\ \mu F}$

Energy stored, $U = \frac{1}{2} C V^2 = \frac{1}{2} \times 0{\cdot}2 \times 10^{-6} \times (50)^2$

$= \mathbf{2{\cdot}5 \times 10^{-4}\ J}$

44. Here, $C = 50\ \mu F$; V = 10 V

$\therefore \quad q = C V = 50 \times 10 = \mathbf{500\ \mu C}$

Energy stored, $U = \frac{1}{2} C V^2 = \frac{1}{2} \times 50 \times 10^{-6} \times (10)^2$

$= \mathbf{2{\cdot}5 \times 10^{-3}\ J}$

45. Here, $C = 300\ \mu F$; V = 200 V

$\therefore \quad q = C V = 300 \times 10^{-6} \times 200 = 6 \times 10^{-2}$ C

When the distance between plates of a capacitor is hal its capacitance inreases by a factor 2 *i.e.*

$C' = 2C = 2 \times 300 = 600\ \mu F$

Therefore, potential between the plates of capacitor,

$$V' = \frac{q}{C'} = \frac{6 \times 10^{-2}}{600 \times 10^{-6}} = \mathbf{100\ V}$$

Initial energy stored in the capacitor,

$$U = \frac{1}{2} C V^2 = \frac{1}{2} \times 300 \times 10^{-6} \times (200)^2 = 6\ J$$

Final energy stored in the capacitor,

$$U' = \frac{1}{2} C' V'^2 = \frac{1}{2} \times 600 \times 10^{-6} \times (100)^2 = 3\ J$$

Therefore, decrease in energy stored, $U - U' = 6 - 3 =$

46. Here, $A = 50\ cm^2 = 50 \times 10^{-4}\ m^2$; $d = 1$ mm $= 10^{-3}$ m

$$(a) \quad C = \frac{\varepsilon_0 A}{d} = \frac{8{\cdot}854 \times 10^{-12} \times 50 \times 10^{-4}}{10^{-3}}$$

$$= 44{\cdot}27 \times 10^{-12}\ F = \mathbf{44{\cdot}27\ pF}$$

(*b*) Now, $q = CV = 44{\cdot}27 \times 10^{-12} \times 45 = \mathbf{1{\cdot}99 \times 10^{-9}\ C}$

Also, $U = \frac{1}{2}CV^2 = \frac{1}{2} \times 44{\cdot}27 \times 10^{-12} \times (45)^2$

$= \mathbf{4{\cdot}48 \times 10^{-8}\ J}$

(*c*) Electric field between the plates of capacitor,

$$E = \frac{V}{d} = \frac{45}{10^{-3}} = \mathbf{4{\cdot}5 \times 10^4\ V\ m^{-1}}$$

47. Here, $C_1 = 400$ pF, $V_1 = 100$ V

$\therefore\ U = \frac{1}{2}C_1 V_1^2 = \frac{1}{2} \times 400 \times 10^{-12} \times (100)^2$

$= \mathbf{2 \times 10^{-6}\ J}$

On connecting the charged capacitor to another capacitor :

Here, $C_2 = 400$ pF

Total capacitance, $C = C_1 + C_2 = 400 + 400 = 800$ pF

Total charge, $q = q_1 + q_2 = C_1 V_1 + 0 = 400 \times 10^{-12} \times 100$

$= 4 \times 10^{-8}$ C

Therefore, common potential,

$$V = \frac{q}{C} = \frac{4 \times 10^{-8}}{800 \times 10^{-12}} = 50\ \text{V}$$

Therefore, energy stored in the system,

$$U = \frac{1}{2}CV^2 = \frac{1}{2} \times 800 \times 10^{-12} \times (50)^2 = \mathbf{10^{-6}\ J}$$

48. Here, $q_1 = 2\ \mu C$; $V_1 = 100$ V ; $q_2 = 1{\cdot}5\ \mu C$ and $V_2 = 60$ V

$\therefore\quad C_1 = \frac{q_1}{V_1} = \frac{2 \times 10^{-6}}{100} = 2 \times 10^{-8}$ F

and $C_2 = \frac{q_2}{V_2} = \frac{1{\cdot}5 \times 10^{-6}}{60} = 2{\cdot}5 \times 10^{-8}$ F

When two capacitors are put into connect :

$C = C_1 + C_2 = 2 \times 10^{-8} + 2{\cdot}5 \times 10^{-8} = 4{\cdot}5 \times 10^{-8}$ F

$q = q_1 + q_2 = 2 + 1{\cdot}5 = 3{\cdot}5\ \mu C = 3{\cdot}5 \times 10^{-6}$ C

Common potential, $V = \frac{q}{C} = \frac{3{\cdot}5 \times 10^{-6}}{4{\cdot}5 \times 10^{-8}} = \mathbf{77{\cdot}78\ V}$

$\therefore\quad q_1' = C_1 V = 2 \times 10^{-8} \times 77{\cdot}78 = \mathbf{1{\cdot}56 \times 10^{-6}\ C}$

and $\quad q_2' = C_2 V = 2{\cdot}5 \times 10^{-8} \times 77{\cdot}78 = \mathbf{1{\cdot}94 \times 10^{-6}\ C}$

Energy stored in the capacitors before connection,

$U = \frac{1}{2}C_1 V_1^2 + \frac{1}{2}C_2 V_2^2$

$= \frac{1}{2} \times 2 \times 10^{-8} \times (100)^2 + \frac{1}{2} \times 2{\cdot}5 \times 10^{-8} \times (60)^2$

$= \mathbf{1{\cdot}45 \times 10^{-4}\ J}$

Energy stored in the capacitors after connection,

$U' = \frac{1}{2}CV^2 = \frac{1}{2} \times 4{\cdot}5 \times 10^{-8} \times (77{\cdot}78)^2$

$= 1{\cdot}36 \times 10^{-4}$ J

49. ***When capacitors are connected in parallel :***

Here, $\frac{1}{2}(C_1 + C_2) \times (3000)^2 = 45$

or $\qquad C_1 + C_2 = 10^{-5}$ ...(*i*)

When capacitors are connected in series :

Now, $\frac{1}{2}\left(\frac{C_1 C_2}{C_1 + C_2}\right) \times (3000)^2 = 4{\cdot}05$

or $\qquad \frac{1}{2}\left(\frac{C_1 C_2}{10^{-5}}\right) \times (3000)^2 = 4{\cdot}05$

or $\qquad C_1 C_2 = 9 \times 10^{-12}$ ...(*ii*)

Solving equations (*i*) and (*ii*), we get

$C_1 = 9 \times 10^{-6}$ F $= \mathbf{9\ \mu F}$

and $\quad C_2 = 10^{-6}$ F $= \mathbf{1\ \mu F}$

50. Here, $C_1 = 7\ \mu$F, V = 10 V

$\therefore\quad U_1 = \frac{1}{2}C_1 V^2 = \frac{1}{2} \times 7 \times 10^6 \times (10)^{-2} = 3{\cdot}5 \times 10^{-4}$ J

Now, $C_2 = 3\ \mu$F, $\quad V = 10$ V

$\therefore\ U_2 = \frac{1}{2}C_2 V^2 = \frac{1}{2} \times 3 \times 10^{-6} \times (10)^2 = 1{\cdot}5 \times 10^{-4}$ J

Therefore, change in energy stored,

$U = U_1 - U_2 = 3{\cdot}5 \times 10^{-4} - 1{\cdot}5 \times 10^{-4}$

$= \mathbf{2{\cdot}0 \times 10^{-4}\ J\ (decrease)}$

The energy is lost as heat and electromagnetic radiation.

51. Here, $C_1 = 6\ \mu$F ; $\quad V_1 = 150$ V

Now, $U_1 = \frac{1}{2}C_1 V_1^2 = \frac{1}{2} \times 6 \times 10^{-6} \times (150)^2 = 6{\cdot}75 \times 10^{-2}$ J

On connecting the two capacitors :

Let C_2 be capacitance of the other capacitor.

Total capacitance, $C = C_1 + C_2 = 6 \times 10^{-6} + C_2$

Total charge, $q = q_1 + q_2 = C_1 V_1 + 0$

$= 6 \times 10^{-6} \times 150 = 9 \times 10^{-4}$ C

Therefore, common potential,

$$V = \frac{q}{C} = \frac{9 \times 10^{-4}}{6 \times 10^{-6} + C_2}$$

Since common potential is 90 V, we have

$\frac{9 \times 10^{-4}}{6 \times 10^{-6} + C_2} = 90 \quad$ or $\quad C_2 = 4 \times 10^{-6}$ F $= \mathbf{4\ \mu F}$

Total energy stored in the system,

$U = \frac{1}{2}CV^2 = \frac{1}{2}(6 \times 10^{-6} + 4 \times 10^{-6}) \times (90)^2$

$= 4{\cdot}05 \times 10^{-2}$ J

Therefore, loss of energy on connecting the two capacitors,

$U_1 - U = 6{\cdot}75 \times 10^{-2} - 4{\cdot}05 \times 10^{-2} = 2{\cdot}7 \times 10^{-2}$

$= \mathbf{0{\cdot}027\ J}$

52. Proceed as in solved problem no. 5.27.

53. Proceed as in solved problem no. 5.27.

54. Proceed as in solved problem no. 5.27.

55. Here, $C_1 = 25\ \mu F = 25 \times 10^{-6}$ F ; $C_2 = 100\ \mu F = 100 \times 10^{-6}$ F

When capacitors are connected in series :

$$C_s = \frac{C_1 C_2}{C_1 + C_2} = \frac{25 \times 10^{-6} \times 100 \times 10^{-6}}{25 \times 10^{-6} + 100 \times 10^{-6}} = 20 \times 10^{-6}\ \text{F}$$

When connected to 120 V battery, charge on the two capacitors,

$q_1 = q_2 = C_s V = 20 \times 10^{-6} \times 120 = 2{\cdot}4 \times 10^{-3}$ C

On connecting the capacitors in parallel :

Total charge, $q = q_1 + q_2 = 2{\cdot}4 \times 10^{-3} + 2{\cdot}4 \times 10^{-3}$

$= 4{\cdot}8 \times 10^{-3}$ C

Total capacitance, $C_p = C_1 + C_2 = 25 \times 10^{-6} + 100 \times 10^{-6}$

$= 125 \times 10^{-6}$ F

(*a*) Potential difference between the plates of each capacitor,

$$V' = \frac{q}{C_p} = \frac{4{\cdot}8 \times 10^{-3}}{125 \times 10^{-6}} = \mathbf{38{\cdot}4\ V}$$

(*b*) Energy stored in the series combination,

$$U = \frac{1}{2}C_s V^2 = \frac{1}{2} \times 20 \times 10^{-6} \times (120)^2 = 0{\cdot}144\ \text{J}$$

Energy stored in parallel combination,

$$U' = \frac{1}{2} C_p V'^2 = \frac{1}{2} \times 125 \times 10^{-6} \times (38 \cdot 4)^2 = 0 \cdot 092 \text{ J}$$

Therefore, energy lost in the process,

$$U - U' = 0{\cdot}144 - 0{\cdot}092 = \mathbf{0{\cdot}052\ J}$$

56. $U = \frac{1}{2} C V^2 = \frac{1}{2} \times 2 \times 10^{-6} \times (200)^2 = \mathbf{0{\cdot}04\ J}$

On inserting dielectric :

$$C' = K C = 2 \times 2 \times 10^{-6} = 4 \times 10^{-6} \text{ F}$$

$$\therefore \quad U' = \frac{1}{2} C' V^2 = \frac{1}{2} \times 4 \times 10^{-6} \times (200)^2 = \mathbf{0{\cdot}08\ J}$$

57. Now, $q = C V = 20 \times 10^{-6} \times 220 = \mathbf{4{\cdot}4 \times 10^{-3}\ C}$

Also, $U = \frac{1}{2} C V^2 = \frac{1}{2} \times 20 \times 10^{-6} \times (220)^2 = \mathbf{0{\cdot}484\ J}$

On inserting dielectric :

$$C' = K C = 55 \times 20 \times 10^{-6} = 1{\cdot}1 \times 10^{-3} \text{ C}$$

$$\therefore \quad V' = \frac{q}{C'} = \frac{4 \cdot 4 \times 10^{-3}}{1 \cdot 1 \times 10^{-3}} = \mathbf{4\ V}$$

and $U' = \frac{1}{2} C' V'^2 = \frac{1}{2} \times 1 \cdot 1 \times 10^{-3} \times (4)^2$

$$= \mathbf{8{\cdot}8 \times 10^{-3}\ J}$$

58. Let A be area of each plate and d be distance between them. Then,

$$C = \frac{\varepsilon_0 A}{d} \qquad \text{...}(i)$$

On introducing dielectric slab :

Let K be dielectric constant of the slab and d', the distance between the plates. Then,

$$C = \frac{\varepsilon_0 A}{d' - t(1 - 1/K)} \qquad \text{...}(ii)$$

From equations (*i*) and (*ii*), we have

$$d' - t\left(1 - \frac{1}{K}\right) = d$$

Here, $d' = d + 3{\cdot}2 \times 10^{-3}$ m and $t = 4$ mm $= 4 \times 10^{-3}$ m

$$\therefore \quad d + 3{\cdot}2 \times 10^{-3} - 4 \times 10^{-3}\left(1 - \frac{1}{K}\right) = d$$

or $\quad 1 - \frac{1}{K} = \frac{3 \cdot 2 \times 10^{-3}}{4 \times 10^{-3}} = 0 \cdot 8$

or $\quad K = 5$

59. ***Before inserting dielectric slab :***

$$C = \frac{\varepsilon_0 A}{d}; q = C V = \frac{\varepsilon_0 A V}{d}$$

or $\quad q = \frac{\varepsilon_0 A V}{5 \times 10^{-3}} \qquad \text{...}(i)$

After inserting dielectric slab :

$$C' = \frac{\varepsilon_0 A}{d - t(1 - 1/K)}, \quad q' = C' V = \frac{\varepsilon_0 A V}{d - t(1 - 1/K)}$$

or $\quad q' = \frac{\varepsilon_0 A V}{5 \times 10^{-3} - 2 \times 10^{-3}(1 - 1/K)} \qquad \text{...}(ii)$

Now, $q' = \frac{125}{100} q$

Using equations (*i*) and (*ii*), we have

$$\frac{\varepsilon_0 A V}{5 \times 10^{-3} - 2 \times 10^{-3}(1 - 1/K)} = \frac{125}{100} \times \frac{\varepsilon_0 A V}{5 \times 10^{3}}$$

or $\quad 5 \times 10^{-3} - 2 \times 10^{-3}\left(1 - \frac{1}{K}\right) = 4 \times 10^{-3}$

or $\quad K = 2$

60. ***Before inserting dielectric slab :***

$$C = \frac{\varepsilon_0 A}{d} = \frac{8 \cdot 854 \times 10^{-12} \times 6 \times 10^{-3}}{3 \times 10^{-3}} = 17 \cdot 7 \times 10^{-12} \text{ F}$$

$$\therefore \quad q = C V = 17{\cdot}7 \times 10^{-12} \times 200 = \mathbf{3{\cdot}54 \times 10^{-9}\ C}$$

Now, proceed as in solved problem no. 5.28.

61. The capacitance of capacitor on introducing dielectric sl

$$C = 5 \times 2 = 10\ \mu\text{F}$$

$$\therefore \quad q = C V = 10 \times 10^{-6} \times 100 = 10^{-3} \text{ C}$$

On removing the dielectric slab :

(*a*) The capacitance of capacitor, $C' = 2\ \mu$F

$$\therefore \quad V' = \frac{q}{C'} = \frac{10^{-3}}{2 \times 10^{-6}} = \mathbf{500\ V}$$

(*b*) Initial energy stored in the capacitor,

$$U = \frac{1}{2} C V^2 = \frac{1}{2} \times 10 \times 10^{-6} \times (100)^2 = 0 \cdot 05 \text{ J}$$

Final energy stored in the capacitor,

$$U' = \frac{1}{2} C' V'^2 = \frac{1}{2} \times 2 \times 10^{-6} \times (500)^2 = 0 \cdot 25 \text{ J}$$

Therefore, work done to remove the dielectric slab,

$$W = U' - U = 0{\cdot}25 - 0{\cdot}05 = \mathbf{0{\cdot}2\ J}$$

62. Proceed as in solved problem no. 5.30.

63. Let r be radius of the metal sphere.

Here, $\frac{dV}{dr} = E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2} = 3 \times 10^6 \text{ V m}^{-1}$

and $\quad V = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r} = 3 \times 10^6 \text{ V}$

Now, $r = \frac{V}{E} = \frac{3 \times 10^6}{3 \times 10^6} = \mathbf{1\ m}$

and $U = \frac{1}{2} C V^2 = \frac{1}{2} \times (4\pi\varepsilon_0 r) \times V^2 = \frac{1}{2} \times \frac{1 \times (3 \times 10^6}{9 \times 10^9}$

$$= \mathbf{500\ J}$$

64. The given arrangement is equivalent to the para combination of three capacitors C_1, C_2 and C_3. The pl area of each of the three capacitors is A/3, while the pl separations in the three capacitors are d, $d + b$ and $d +$ respectively.

$$\therefore \quad C_1 = \frac{\varepsilon_0 A/3}{d}, \quad C_2 = \frac{\varepsilon_0 A/3}{d + b} \quad \text{and} \quad C_3 = \frac{\varepsilon_0 A/}{d + 2}$$

Hence, equivalent capacitance of the arrangement,

$$C = C_1 + C_2 + C_3$$

On substituting for C_1, C_2 and C_3, it can be obtained t

$$C = \frac{\varepsilon_0 A(3d^2 + 6bd + 2b^2)}{3d(d + b)(d + 2b)}$$

65. The system of three plates is equivalent to the ser combination of two capacitors C_1 and C_2. It follows t

$$C_1 = \frac{\varepsilon_0 \varepsilon_1 A}{d_1} \quad \text{and} \quad C_2 = \frac{\varepsilon_0 \varepsilon_2 A}{d_2}$$

The equivalent capacitance is given by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{d_1}{\varepsilon_0 \varepsilon_1 A} + \frac{d_2}{\varepsilon_0 \varepsilon_2 A}$$

$$= \frac{1}{\varepsilon_0 A}\left(\frac{d_1 \varepsilon_2 + d_2 \varepsilon_1}{\varepsilon_1 \varepsilon_2}\right)$$

or $\quad C = \frac{\varepsilon_0 \varepsilon_1 \varepsilon_2 A}{d_1 \varepsilon_2 + d_2 \varepsilon_1}$

6. The arrangement is equivalent to three capacitors C_1, C_2 and C_3, such that C_1 is parallel to the series combination of C_2 and C_3.

Now, $C_1 = \frac{\varepsilon_0 K_1 A/2}{d} = \frac{\varepsilon_0 K_1 A}{2d}$;

$$C_2 = \frac{\varepsilon_0 K_2 A/2}{d/2} = \frac{\varepsilon_0 K_2 A}{d}$$

and $C_3 = \frac{\varepsilon_0 K_3 A/2}{d/2} = \frac{\varepsilon_0 K_3 A}{d}$

The equivalent capacitance is given by

$$C = C_1 + \frac{C_2 C_3}{C_2 + C_3}$$

$$= \frac{\varepsilon_0 K_1 A}{2d} + \frac{(\varepsilon_0 K_2 A/d) \times (\varepsilon_0 K_3 A/d)}{\varepsilon_0 K_2 A/d + \varepsilon_0 K_3 A/d}$$

$$= \frac{\varepsilon_0 K_1 A}{2d} + \frac{\varepsilon_0 K_2 K_3 A}{(K_2 + K_3) d} = \frac{\varepsilon_0 A}{d}\left(\frac{K_1}{2} + \frac{K_2 K_3}{K_2 + K_3}\right)$$

Here, $K_1 = 4$; $K_2 = 6$; $K_3 = 2$, $A = 1\ \text{cm}^2 = 10^{-4}\ \text{m}^2$

and $d = 2\ \text{mm} = 2 \times 10^{-3}\ \text{m}$

$$\therefore \quad C = \frac{8 \cdot 854 \times 10^{-12} \times 10^{-4}}{2 \times 10^{-3}}\left(\frac{4}{2} + \frac{6 \times 2}{6 + 2}\right)$$

$= 1{\cdot}55 \times 10^{-12}$ F = **1·55 pF**

Competitive Examination File (Unit I)

REVISION AT A GLANCE

Chapter 1. Coulomb's Law

☐ **Frictional electricity.** *Electricity developed on bodies, when they are rubbed against each other.*

The bodies get charged due to transfer of electrons from one body to the other.

☐ **Smallest amount of charge.** Charge (e) on an electron or a proton ($e = \pm 1{\cdot}6 \times 10^{-19}$ C)

☐ **Additive nature of charge.** *The total charge of a system is equal to the algebraic sum of all individual charges of the sys*

☐ **Quantization of charge.** *Charge (q) on a body is always integral multiple of e i.e.* $q = \pm n\,e$.

This fact is also known as ***discrete nature of charge.***

☐ **Conservation of charge.** *Net charge on an isolated system always remains constant.* In other words, *charge can neith created nor destroyed.*

☐ **Coulomb's law in electrostatics.** *Two electrical charges always attract or repel each other with a force which is dir proportional to the product of the charges and inversely proportional to the square of the distance between them.*

Mathematical form **: 1.** In vacuum (or air), $F = \dfrac{1}{4\pi\varepsilon_0} \cdot \dfrac{q_1 q_2}{r^2}$

Here, $\varepsilon_0 = 8{\cdot}854 \times 10^{-12}\ \text{C}^2\ \text{N}^{-1}\ \text{m}^2$ is ***absolute permittivity*** of vacuum.

2. In a dielectric medium, $F = \dfrac{1}{4\pi\varepsilon_0 K} \cdot \dfrac{q_1 q_2}{r^2}$

Here, K is called ***dielectric constant.*** It is also called ***relative permittivity*** (ε_r) of the medium.

☐ **Coulomb's law in vector form. 1.** Force on charge q_2 due to q_1,

$$\vec{F}_{21} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^2}\,\hat{r}_{12} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r^3}\,\vec{r}_{12}$$

Here, r is distance between the two charges, $\hat{r}_{12}$ is unit vector and $\vec{r}_{12} = r\,\hat{r}_{12}$ is the vector from charge q_1 to q_2.

2. If charges q_1 and q_2 are located at the points, whose position vectors are $\vec{r}_1$ and $\vec{r}_2$, then

$$\vec{F}_{21} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{|\vec{r}_2 - \vec{r}_1|^3}\,(\vec{r}_2 - \vec{r}_1)$$

☐ **Unit of charge.** It is **coulomb (C)** in SI.

One coulomb is that charge, which will repel an equal and similar charge with a force of 9 × 10^9 N, when placed at a distan 1 m from it in vacuum (or air).

☐ **Dielectric constant.** *The dielectric constant of a medium is the ratio of the force between two charges placed at a certain dist apart in vacuum (or air) to the force between the same two charges placed at the same distance apart in that medium.*

☐ **Principle of superposition.** *When a number of charges are interacting, the total force on a particular charge is equal t vector sum of the forces exerted on it by all other charges.*

Some Useful Facts :

1. The charges developed on the bodies during the process of rubbing are due to the transfer of *electrons from one to the other.*

2. Coulomb's law in electrostatics holds only for stationary and point charges.

3. When the same two charges located in air are placed in a dielectric medium without altering the distance betw them, electrostatic force always decreases.

4. A system of charge is said to be in equilibrium, if the net force experienced by each charge of the system is zer

5. Electrostatic force between two charges is not altered due to the presence of a third charge in their vicinity.

Chapter 2. Electric Field

☐ **Electric field.** *The space around an electric charge, in which its effect can be experienced.*

Quantitatively : *Electric field at a point is equal to the force per unit test charge acting on a vanishingly small positive test ch placed at that point.*

Mathematically : $\vec{E} = \underset{q_0 \to 0}{\mathrm{Lt}} \dfrac{\vec{F}}{q_0}$, where q_0 is vanishingly small test charge.

Unit. In SI, the unit of electric field is **newton coulomb^{-1} (N C^{-1}).**
It is also expressed as **volt metre^{-1} (V m^{-1}).**

☐ **Electric field due to a point charge.** $E = \dfrac{1}{4\pi\varepsilon_0} \cdot \dfrac{q}{r^2}$, where r is distance of the observation point from the source
ge q.

☐ **Electric dipole.** *A system of two equal and opposite charges separated by a certain distance.*

☐ **Electric dipole moment.** *The product of the magnitude of either charge and the length of the electric dipole.*

Mathematically : $\vec{p} = q(2\,\vec{a})$

Here, $2\,\vec{a}$ is length of the electric dipole and is a vector from charge $-\,q$ to $+\,q$ constituting the dipole.

Unit. Its unit in SI is **coulomb metre (C m).**

☐ **Electric field on axial line of the electric dipole.** 1. At the point at a distance r from the centre of the electric dipole,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{2pr}{(r^2 - a^2)^2}$$

2. For dipole of small length $(2a << r)$, $E = \dfrac{1}{4\pi\varepsilon_0} \cdot \dfrac{2p}{r^3}$

☐ **Electric field on equitorial line of the electric dipole. 1.** At the point at a distance r from the centre of the electric
le,

$$\vec{E} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{p}{(r^2 + a^2)^{3/2}}$$

2. For dipole of small length $(2a << r)$, $E = \dfrac{1}{4\pi\varepsilon_0} \cdot \dfrac{p}{r^3}$

☐ **Electric field due to a circular loop of charge. 1.** For a circular loop of radius a and total charge q, the electric field at
oint on its axis at a distance x from its centre,

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{qx}{(a^2 + x^2)^{3/2}}$$

2. When the distance of observation point is very large $(x >> a)$, then

$$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{x^2}$$

3. At the centre of the circular loop of charge, $E = 0$

☐ **Torque on an electric dipole placed in a uniform electric field.**

1. For an electric dipole of dipole moment $\vec{p}$ placed in electric field $\vec{E}$,

$$\vec{\tau} = \vec{p} \times \vec{E}$$

2. If θ is angle between the directions of $\vec{p}$ and $\vec{E}$, then

$$\tau = p\,E \sin\theta$$

☐ **Potential energy of an electric dipole in a uniform electric field.**

1. If the electric dipole is rotated from initial orientation making angle θ_1 with the electric field to the final orientation
ing angle θ_2 with the field, then

$$U = p\,E\,(\cos\theta_1 - \cos\theta_2)$$

2. If the electric dipole is rotated from its initial orientation perpendicular to the field to the final orientation so as to
e an angle θ with the field, then

$$U - p\,E\cos\theta = -\,\vec{p}\,.\,\vec{E}$$

☐ **Electric line of force.** *It is the path straight or curved, such that tangent to it at any point gives the direction of electric field*
at point.

ne Useful Facts :

1. The test charge used to measure electric field at a point has to be vanishingly small. If the test charge is not vanishingly
ll, then the test charge may bring about a change in the electric field at the observation point.

For this, one is advised to understand the difference between the statement `*the force experienced by a unit positive test*
ge' and `*the force experienced per unit positive test charge.*' A unit positive charge is quite large and if it is used as the test
ge, it will cause a change in the value of electric field at the observation point.

2. The unit of electric dipole moment is **C m** and not **mC**. It is because, **mC** is used as millicoulomb.

3. The direction of electric field at a point on the axial line of an electric dipole is same as that of $\vec{p}$.

4. The direction of electric field at a point on equitorial line of an electric dipole is opposite to that of $\vec{p}$.

5. For the observation point at very large distance from the charged circular loop ($x >> a$), the loop behaves as a p charge.

6. No torque acts on a dipole, when it is aligned along the direction of electric field.

7. The electrostatic potential energy of the dipole is maximum, when it is aligned antiparallel to the direction of the elec field.

8. The electric lines of force do not exist but what they represent is a reality.

It gives the path along which positive test charge would move, when free to do so.

In a uniform electric field, the lines of force are parallel lines. The electric lines of force crowd near each other in regi of strong electric field. The relative closeness of the lines of force at different points in the electric field gives an estimat the strength of the electric field at these points.

Chapter 3. Electric Potential

☐ **Electric potential difference.** *The electric potential difference between two points in an electric field is defined as the amo of work done per unit positive test charge in moving the test charge from one point to the other against the electrostatic force due to field.*

Mathematically : If W_{AB} is work done in moving a small positive test charge q_0 from point A to B in the electrost field of charge q, then potential difference between points A and B,

$$V_B - V_A = \frac{W_{AB}}{q_0} = \frac{1}{4\pi\varepsilon_0} \cdot q\left(\frac{1}{r_B} - \frac{1}{r_A}\right)$$

Here, r_A and r_B are distances of points A and B from the source charge q.

Unit. Its unit in SI is volt (V)

1 volt (V) = 1 joule coulomb^{-1} (J C^{-1})

☐ **Electric potential.** *The electric potential at a point in an electric field is defined as the amount of work done per unit posi test charge in moving the test charge from infinity to that point against the electrostatic force due to the field.*

Mathematically : If $W_{\infty A}$ is work done in moving a small positive test charge from infinity to point A in the electrost field of charge q, then potential at point A,

$$V = \frac{W_{\infty A}}{q_0} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r}$$

Here, r is the distance of the point A from the source charge q.

Unit. Its unit is also volt. **1 V = 1 J s^{-1}**

☐ **Electric potential due to group of charges.** The electric potential at a point due to a group of charges is equal to algebraic sum of the electric potentials due to individual charges at that point. It is because of the reason that electric poter is a scalar quantity.

$$V = \frac{1}{4\pi\varepsilon_0} \cdot \left(\frac{q_1}{r_1} + \frac{q_2}{r_2} + \frac{q_3}{r_3} + \ldots\ldots \frac{q_n}{r_n}\right) = \frac{1}{4\pi\varepsilon_0} \sum_{i=1}^{n} \frac{q_i}{r_i}$$

☐ **Potential gradient.** *The rate of change of potential with distance at a point is called potential gradient at that point.*

The electric field at a point is equal to negative potential gradient at that point.

Mathematically : $E = -\dfrac{dV}{dr}$

Unit. Its unit in SI is **volt metre^{-1} (V m^{-1}).**

☐ **Equipotential surface.** *The surface at every point of which, the electric potential is same, is called equipotential surface.*

Two equipotential surfaces never intersect each other.

☐ **Electrostatic potential energy of a system of charges.** *It is defined as the work done to put the charges constituting system at their respective locations after having been removed to infinity.*

Mathematically : **1.** Potential energy of the system of two charges q_1 and q_2,

$$U = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1 q_2}{r_{12}},$$

2. Potential energy of the system of three charges q_1, q_2 and q_3,

$$U = \frac{1}{4\pi\varepsilon_0} \cdot \left(\frac{q_1 q_2}{r_{12}} + \frac{q_2 q_3}{r_{23}} + \frac{q_3 q_1}{r_{31}}\right),$$

where r_{12}, r_{23} and r_{31} have their usual meanings.

Unit. Its unit in SI is **joule (J) or electron volt (eV).**

1 eV = 1·6 × 10^{-19} J

me Useful Facts :

1. The work done in moving a test charge between two points in an electric field is independent of the path followed veen the two points.

2. The work done in moving a test charge over a closed path in an electric field is always zero.

The above two results hold for the reason that electrostatic force between two charges obeys inverse law *i.e.* electrostatic d is inverse square field.

3. The work done per unit positive test charge from a point A to point B is equal to $V_B - V_A$ *i.e.* potential difference between points B and A (and not between points A and B).

4. Electric potential at any point inside a charged conductor is always equal to that at a point on its surface *i.e.* it is same stant) every where.

As a result of it, the electric field inside a charged conductor is zero.

5. For a point outside the charged spherical conductor, the whole charge appears to be concentrated at its centre.

6. The electrostatic potential increases steadily as one moves against the direction of electric field and it decreases in direction of electric field.

The above result is a consequence of negative sign in the relation : $E = -\frac{dV}{dr}$

7. The electric field is always at right angle to the equipotential surface.

8. No work is done in moving a test charge between two points on an equipotential surface.

9. If work has to be done in moving one of the charges of a system from one point to some other, then electrostatic potential rgy of the system increases by an amount equal to the work done in moving the charge.

Chapter 4. Gauss's Theorem

☐ **Electric flux.** *The electric flux through a small surface is defined as the electric lines of force passing through that area, when normally to the lines of force.*

Mathematically : $\phi = \vec{E} \cdot \Delta \vec{S}$,

ere $\vec{E}$ is the electric field and $\Delta \vec{S}$ is the area vector representing the elementary surface area.

Unit. In SI, unit of electric flux is **newton metre^2 coulomb^{-1} (N m^2 C^{-1}).**

☐ **Gauss's theorem.** *It states that the total outward electric flux through a closed surface is* $\frac{1}{\varepsilon_0}$ *times the charge enclosed by the ed surface.*

Mathematically: $\oint \vec{E} \cdot d\vec{S} = \frac{q}{\varepsilon_0}$,

ere q is charge enclosed by the closed surface.

☐ **Gaussian surface.** *Any closed surface around the charge distribution (may be a point charge, a line charge, a surface charge or lume charge) so that Gauss's theorem can be conveniently applied to find electrical field due to it is called the gaussian surface.*

☐ **Electric field due to infinitely long straight wire of linear charge density λ :**

$$E = \frac{\lambda}{2\pi \varepsilon_0 r},$$

ere r is perpendicular distance of the observation point from the wire.

☐ **Electric field between two infinite thin plane parallel sheets of charge density σ and $-\sigma$:**

$$E = \frac{\sigma}{\varepsilon_0}$$

☐ **Electric field due to infinite thin plane sheet of charge density σ :**

$$E = \frac{\sigma}{2\varepsilon_0}$$

☐ **Electric field due to spherical shell of charge density σ and radius R :**

$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}$, for $r > R$ (outside the shell)

$E = 0$, for $r < R$ (inside the shell)

$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{R^2}$, for $r > R$ (at the surface)

Here, $q = 4\pi R^2 \sigma$

☐ **Electric field due to a solid sphere of charge density ρ and radius R :**

$E = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q}{r^2}$, for $r > R$ (outside the sphere)

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{qr}{R^3}, \quad \text{for } r < R \quad \text{(inside the sphere)}$$

$$E = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{R^2}, \quad \text{for } r = R \quad \text{(at the surface)}$$

Here, $q = \frac{4}{3}\pi R^3 \rho$

Some Useful Facts :

1. The total electrical flux through a closed surface is not affected by the charge present outside the surface. It depen only upon the charges enclosed by the closed surface. The electric flux through a small portion of the closed surface is affect by the charges present outside the surface.

2. The electric flux through a small portion of the closed surface may change, if the charges inside the closed surfa are moved to the new positions.

3. The total electric flux through a closed surface is not affected, if the charges inside the closed surface are moved new positions.

4. For both the spherical shell and the sphere, electric field at a point outside is same as if the charge is concentrated their centre.

5. Inside a spherical shell, electric potential is zero. It is zero inside a sphere also, provided sphere is conducting.

Chapter 5. Capacitors

☐ **Behaviour of a charged conductor. 1.** Charges reside only at the surface of the charged conductor.
2. The electric potential is constant at the surface and inside the conductor.
3. The electric field is zero inside the conductor and just outside it, the electric field is normal to the surface.

☐ **Electrical capacitance.** *The ability of a conductor to store charge is called its electrical capacitance.*

Mathematically : $C = \frac{q}{V}$

Unit. Its unit in SI is **farad (F).**

1 farad (F) = 1 coulomb volt^{-1} (C V^{-1})

☐ **Capacitance of a spherical conductor.** $C = 4\pi\varepsilon_0 r$
Here, r is radius (in metre) of the spherical conductor.

☐ **Capacitor.** *An arrangement for storing a very large amount of charge.*
Principle. The capacitance of a conductor gets increased greatly, when an earth connected conductor is placed near

☐ **Parallel plate capacitor.** $C = \frac{\varepsilon_0 A}{d}$ (when air is between the plates)

$C = \frac{\varepsilon_0 K A}{d}$ (when dielectric is between the plates)

Here, A is area of each plate and d is separation between the two plates.

☐ **Spherical capacitor.** $C = 4\pi\varepsilon_0 \frac{ab}{b-a}$

Here, a and b are the radii of inner and outer coatings (spherical shells) of the spherical capacitor.

☐ **Cylindrical capacitor.** $C = 2\pi\varepsilon_0 \frac{l}{\log_e \frac{b}{a}} = 2\pi\varepsilon_0 \cdot \frac{l}{2{\cdot}303 \log_{10}\frac{b}{a}}$

Here, a and b are the radii of the inner and outer coatings (cylindrical shells) and l is the length of the either coating the cylindrical capacitor.

☐ **Capacitors in series.** $\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}$

☐ **Capacitors in parallel.** $C = C_1 + C_2 + C_3$

☐ **Energy stored in a capacitor.** Work done in charging a capacitor gets stored in the capacitor in the form of its electrosta potential energy.

Mathematically : $U = \frac{1}{2}CV^2 = \frac{1}{2}qV = \frac{1}{2}\frac{q^2}{C}$

☐ **Polar atom.** *The atom (or molecule) in which the positive and negative charges possess asymmetric charge distribution abo its centre.*

☐ **Polarisation.** *The stretching of the atoms of a dielectric slab (displacement of the charges in the atoms) under the action of applied electric field.*

Due to polarisation, equal and opposite induced charges are developed on the two faces of the slab and an electric field alled electric field due to polarisation is produced. It opposes the applied electric field (E_0). As a result, due to the risation of the dielectric, the strength of the electric field gets reduced inside it.

The reduced value of electric field in a polarised dielectric is given by

$$E = E_0 = E_p$$

☐ **Polarisation density.** *The induced dipole moment developed per unit volume in a dielectric slab on placing it inside the electric is called polarisation density.*

☐ **Dielectric constant.** *The ratio of the strength of applied electric field to the strength of reduced value of electric field on inserting ielectric slab between the plates of a capacitor is called the dielectric constant of the slab.*

☐ **Dielectric strength.** *The maximum value of electric field (or potential gradient) that can be applied to the dielectric without its ric breakdown is called dielectric strength of the dielectric.*

Unit. Its unit in SI is **V m^{-1}** (same as that of electric field).

☐ **Effect of dielectric slab on the capacitance of a parallel plate capacitor.**

1. When a dielectric slab of dielectric constant K and thickness t ($t << d$) is introduced between the plates, then

$$C = \frac{\varepsilon_0 A}{d - t(1 - 1/K)}$$

2. When a conducting slab of thickness t ($t < d$) is introduced, then

$$C = \frac{\varepsilon_0 A}{d(1 - t/d)}$$

☐ **Principle of Van de Graaff generator.** *Electric discharge takes place in air or gases easily at pointed conductors and that a w conductor continues accepting charge through its inner surface irrespective of the fact, howsoever large its potential may grow.*

☐ **Atmospheric electricity. 1.** Earth has an electric field of about 100 V m^{-1} at its surface in downward direction.

2. The surface of earth has a negative surface charge density of about 10^{-9} C m^{-2}.

3. Atmosphere has a slight conductivity up to 50 km. Due to this, about + 1800 C of charge is pumped every second the earth. The earth does not get discharged, as an equal amount of negative charge is continuously pumped into earth to thunder storms and lightning occurring over the earth.

4. Beyond 50 km, the atmosphere is a good conductor.

ne Useful Facts :

1. The capacitors are connected in parallel to increase the capacitance.

2. The capacitors are connected in series to decrease the capacitance.

3. When a dielectric slab of dielectric osnstant K is introduced between the plates of a charged air-capacitor (battery nnected after charging), then

(*a*) capacitance increases by a factor K.
(*b*) potential difference decreases by a factor K.
(*c*) charge on the capacitor remains unaffected.
(*d*) electrostatic potential energy stored in the capacitor decreases by a factor K.

4. When a dielectric slab of dielectric constant K is introduced between the plates of an air capacitor (battery remains connected across the capacitor), then

(*a*) capacitance of the capacitor increases by a factor K.
(*b*) potential difference across capacitor remains unaffected.
(*c*) charge on the capacitor increases by a factor K.
(*d*) electrostatic potential energy stored in the capacitor increases by a factor K.

5. The dielectric slab can be removed from the space between the plates of a charged capacitor only by performing work. ever, the work done appears as increase in the potential energy of the capacitor.

6. When the space between the two plates of a capacitor is filled with two dielectric slabs, then the two parts of the capacitor be looked upon as the combination of two capacitors.

The capacitor behaves as a parallel combination of the two subcapacitors, if each slab is of thickness equal to separation the other hand, it behaves as a series combination of the two subcapacitors, if the total thickness of the two slabs put her is equal to *d*.

NUMERICAL PROBLEMS FROM COMPETITIVE EXAMINATIONS

Chapter 1. Coulomb's Law

Problem 1.01. Two equally charged identical metal res A and B repel each other with a force 2·0 × 10^{-5} N. her identical uncharged sphere C is touched to A and then placed at the mid point between A and B. What is the net electric force on C ? (*Roorkee, 1981*)

Sol. Consider that two identical spheres A and B each having charge q are placed at a distance r apart as shown in

Fig. 1.01. The two spheres repel each other with a force of $2{\cdot}0 \times 10^{-5}$ N.

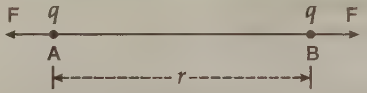

Fig. 1.01.

Now, $$F = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q\times q}{r^2}$$

$$\therefore \quad \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{r^2} = 2{\cdot}0\times10^{-5} \qquad ...(i)$$

When an identical uncharged sphere C is touched to A, both will share the charge on A equally *i.e.* each of the spheres A and C will possess charge $q/2$. The sphere C placed at the mid point between A and B experiences forces F_{CA} (due to sphere A) and F_{CB}(due to sphere B) in the directions as shown in Fig 1.02.

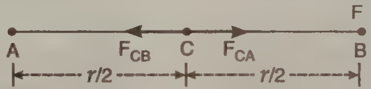

Fig. 1.02.

Now, F $$F_{CA} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q/2\times q/2}{(r/2)^2}$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{r^2} \qquad \text{(along CB)}$$

and $$F_{CB} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q/2\times q}{(r/2)^2}$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{2q^2}{r^2} \qquad \text{(along CA)}$$

Since $F_{CA} >> F_{CA}$, the resultant force on the sphere C is given by

$$F' = F_{CB} - F_{CA}$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{2q^2}{r^2} - \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{r^2}$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{r^2} \qquad \text{(along CA)}$$

Using equation (*i*), we have

$$F' = 2{\cdot}0\times10^{-5}\ \text{N} \qquad \text{(along CA)}$$

Problem 1.02. Two identical charged spheres are suspended by strings of equal lengths. The strings make an angle 30° with each other. When suspended in a liquid of density 800 kg m^{-3}, the angle remains the same. What is the dielectric constant of the liquid ? The density of the material of the sphere is 1600 kg m^{-3}.

(*Roorkee, 1988 ; I.I.T. 1976*)

Sol. The two spheres A and B each of weight W and each carrying charge q, when suspended by strings of equal lengths, come to rest so that the strings make an angle of 30° with each other. Therefore, each string will make an angle of 15° with the vertical [Fig 1.03].

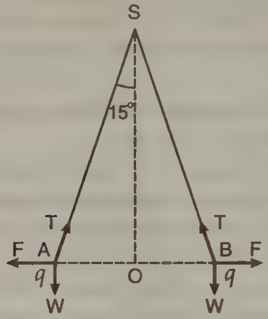

Fig. 1.03

Following forces act on a charged sphere :

(*i*) Weight W acting vertically downwards.

(*ii*) Tension T in the string along AS.

(*iii*) Electrostatic force F on one sphere due to the oth

As the sphere A is in equilibrium, the three forces W and T acting on it, can be represented by the the three sic SO, OA and AS respectively of the triangle AOS. Therefo

$$\frac{W}{SO} = \frac{F}{OA} = \frac{T}{AS}$$

Here, density of the material of the sphere,

$$\rho = 1600\ \text{kg m}^{-3}$$

If V is volume of the sphere, then

$$W = V\rho g = V\times1600\times9{\cdot}8\ \text{N}$$

Also, $$F = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{(AB)^2}$$

From equation (*i*), we have

$$F = W\times\frac{OA}{SO}$$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{(AB)^2} = V\times1600\times9{\cdot}8\ \tan 15° \qquad ...$$

When spheres are suspended in a liquid. Suppose the t spheres are suspended in a liquid of dielectric constant K shown in Fig. 1.04. The weight of the sphere decreases to (say) due to upthrust and electrostatic force between t spheres decreases to F′ (say) due to liquid as the dielect medium. However, the angle between the two strings remai the same.

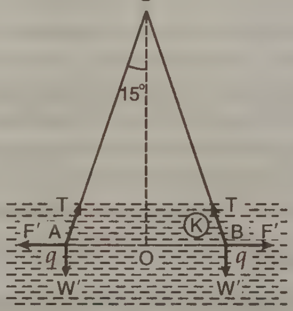

Fig. 1.04

The electrostatic force between the two spheres,

$$F' = \frac{1}{4\pi\varepsilon_0 K}\cdot\frac{q^2}{AB^2}$$

The apparent weight of the sphere,

$$W' = W - \text{upthrust}$$

If σ is density of the liquid, then

$$W' = V\rho g - V\sigma g = V(\rho - \sigma) g$$

Since density of the liquid, $\sigma = 800 \text{ kg m}^{-3}$, we have

$$W' = V \times (1600 - 800) \times 9{\cdot}8$$
$$= V \times 800 \times 9{\cdot}8$$

As the sphere is in equilibrium, the three forces <$E ıan W prime by the three sides SO, AO and AS ɔectively of the triangle AOS. Therefore,

$$\frac{W'}{SO} = \frac{F'}{OA} = \frac{T'}{AS}$$

From the above equation, we have

$$F' = W' \times \frac{OA}{SO}$$

or $$\frac{1}{4\pi\varepsilon_0 K} \cdot \frac{q^2}{(AB)^2} = V \times 800 \times 9{\cdot}8 \tan 15° \qquad ...(iii)$$

Dividing the equation (*ii*) by (*iii*), we have

$$K = \frac{V \times 1600 \times 9{\cdot}8 \times \tan 15°}{V \times 800 \times 9{\cdot}8 \tan 15°} = 2$$

Problem 1.03. Three particles each of mass 1 g and ying a charge *q* are suspended from a common point by ılated massless strings, each 100 cm long. If the particles in equilibrium and are located at the corners of an ilateral triangle of sides of length 3 cm, calculate the rge *q* on each particle. Take $g = 10 \text{ m s}^{-2}$. (*I.I.T. 1988*)

ɔught Process

1. *Each particle is under the action of three forces namely its weight, tension in the string and the resultant electrostatic force on it due to the other two particles.*
2. *For the three particles to be in equilibrium, the net force on each particle should be zero.*

Sol. Three particles each of mass 1 g and charge *q* are ɔended from point S with the help of three threads SA, SB SC each of length 100 cm. In equilibrium, the three rges are located at the corners of an equilateral triangle C of sides of length 3 cm as shown in Fig. 1.05.

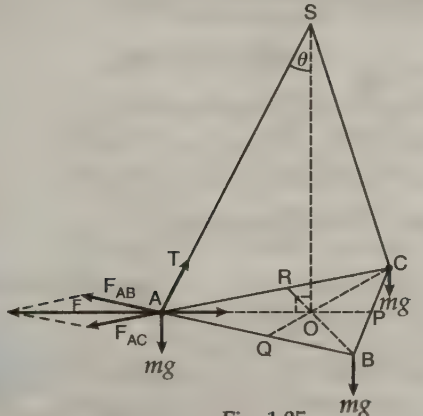

Fig. 1.05.

The point O is vertically below the point of suspension ıd is centroid of the triangle ABC.

Consider the particle A. It is under the effect of the ɔwing three forces :

(*i*) Weight *m g* acting vertically downwards.

(*ii*) Tension T in the string along AS.

(*iii*) Electrostatic force F, which is resultant of the forces, F_{AB} and F_{AC} acting on it A due to particles B and C respectively.

Now, AB = AC = 3 cm = 03 m

Therefore, $$F_{AB} = F_{AC} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q^2}{(0{\cdot}03)^2}$$

$$= 9 \times 10^9 \times \frac{q^2}{9 \times 10^{-4}}$$

$$= 10^{13} q^2$$

The forces F_{AB} and F_{AC} are inclined at 60°. Therefore,

$$F = (F_{AB}^2 + F_{AC}^2 + 2 F_{AB} F_{AC} \cos 60°)^{1/2}$$

$$= \left[(10^{13} q^2)^2 + (10^{13} q^2)^2 + 2 \times 10^{13} q^2 \times 10^{13} q^2 \times 0{\cdot}5\right]^{1/2}$$

$$= 10^{13} q^2 \sqrt{1+1+1}$$

$$= \sqrt{3} \times 10^{13} q^2 \qquad \text{(along OA)}$$

Since $m = 1 \text{ g} = 10^{-3} \text{ kg}$ and $g = 10 \text{ m s}^{-2}$,

$$m g = 10^{-3} \times 10 = 10^{-2} \text{ N} \quad \text{(vertically downwards)}$$

Since the particle A is in equilibrium, the forces F, *m g* and T acting on the particle A can be represented respectively by the sides OA, SO and AS of the triangle OAS. Therefore,

$$\frac{F}{OA} = \frac{mg}{SO} = \frac{T}{AS}$$

or $$F = mg \frac{OA}{SO} = mg \tan\theta, \qquad ...(i)$$

where θ is the angle the string AS makes with the vertical.

To find tan θ : For the sake of clarity ; in Fig. 1.06, the equilateral Δ ABC of Fig. 1.05 has been reproduced.

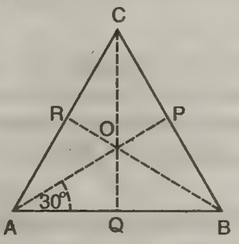

Fig. 1.06

Obviously, ∠ OAQ = 30° and from right angled triangle AQO, we have

$$\cos 30° = \frac{AQ}{AO} = \frac{\frac{1}{2} AB}{AO}$$

or $$AO = \frac{AB}{2\cos 30°} = \frac{3}{2\sqrt{3}/2} = \sqrt{3} \text{ cm}$$

Since AO < < SO, the angle θ is also very small and therefore

$$\tan\theta \approx \sin\theta = \frac{AO}{AS} = \frac{\sqrt{3}}{100}$$

Substituting for F, *mg* and tan θ in equation (*i*), we have

$$\sqrt{3} \times 10^{13} q^2 = 10^{-2} \frac{\sqrt{3}}{100}$$

or $\quad q^2 = 10^{-17} = 10 \times 10^{-18}$

or $\quad q = 3{\cdot}162 \times 10^{-9}$ C

Problem 1.04. A small ball of mass 2×10^{-3} kg having a charge of 1 μC is suspended by a string of length 0·8 m. Another identical ball having the same charge is kept at the point of suspension. Determine the minimum horizontal velocity, which should be imparted to the lower ball so that it can make complete revolution. *(I.I.T. 2001)*

Thought Process

1. *The suspended charged ball will be just able to complete the revolution, if the necessary centripetal force required at the highest point of the vertical circular path is provided by resultant of its weight and electrostatic repulsion between the two charged balls.*
2. *When the suspended charged ball goes from lowest to the highest point, electrostatic potential energy remains the same. Therefore, increase in gravitational potential energy of the ball is equal to decrease in its kinetic energy.*

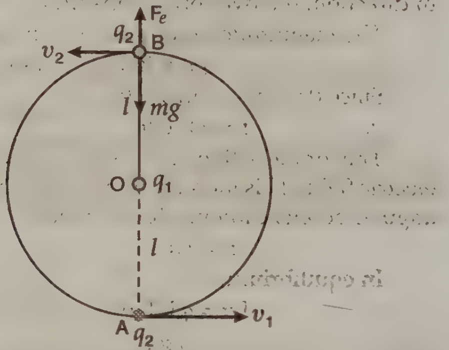

Fig. 1.07

Sol. Here, $q_1 = q_2 = 1\mu\text{C} = 10^{-6}\,\text{C}\,; l = 0{\cdot}8\,\text{m}\,; m = 2 \times 10^{-3}\,\text{kg}$

Suppose that the charged ball A is imparted horizo velocity v_1 at the lowest point A, so that it can just complete revolution [Fig. 1.07]. It requires that tension i string at the highest point is zero.

At the highest point B : Let v_2 be velocity of the b the highest point. The required centripetal force $\frac{m v_2}{l}$ provided by the resultant of weight ($m\,g$) of the suspen ball and the electrostatic repulsion (F_e) between the charged balls *i.e.*

$$\frac{m v_2^2}{l} = m\,g - F_e \quad \text{or} \quad \frac{m v_2^2}{l} = m\,g - \frac{1}{4\pi\varepsilon_0} \cdot q$$

$$\text{or} \quad v_2^2 = g\,l - \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1\,q_2}{m\,l}$$

$$= 9{\cdot}8 \times 0{\cdot}8 - \frac{9 \times 10^9 \times 10^{-6} \times 10^{-6}}{2 \times 10^{-3} \times 0{\cdot}8}$$

$$= 7{\cdot}84 - 5{\cdot}625 = 2{\cdot}215\ \text{m}^2\,\text{s}^{-2}$$

When the suspended ball goes from point A to B :

Increase in gravitational potential energy

$$= m\,g \times 2\,l = 2 \times 10^{-3} \times 9{\cdot}8 \times 2 \times 0{\cdot}8 = 31{\cdot}36 \times 10$$

Decrease in kinetic energy

$$= \frac{1}{2} m\,v_1^2 - \frac{1}{2} m\,v_2^2 = \frac{1}{2} m\,(v_1^2 - v_2^2)$$

$$= \frac{1}{2} \times 2 \times 10^{-3}\,(v_1^2 - 2{\cdot}215)$$

From conservation of mechanical energy,

$$\frac{1}{2} \times 2 \times 10^{-3}\,(v_1^2 - 2{\cdot}215) = 31{\cdot}36 \times 10^{-3}$$

$$\text{or} \quad v_1^2 = \frac{2 \times 31{\cdot}36 \times 10^{-3}}{2 \times 10^{-3}} + 2{\cdot}215$$

$$\text{or} \quad v_1 = \sqrt{31{\cdot}36 + 2{\cdot}215} = 5{\cdot}79\ \text{m s}^{-1}$$

Chapter 2. Electric Field

Problem 2.01. Four charges of + 4, − 3, + 2 and + 3 coulomb are placed at the corners of a square of each side 1 m. Find the electric field at the centre of the square.

Given, $\varepsilon_0 = 8{\cdot}85 \times 10^{-12}\ \text{C}^2\,\text{N}^{-1}\,\text{m}^{-2}$

(I.S.M. Dhanbad, 1989)

Sol. Fig. 2.01 shows the four charges A, B, C and D of a square of each side 1 m. The electric field at the centre O of the square will be in the directions as shown.

Let AO = BO = CO = DO = r.

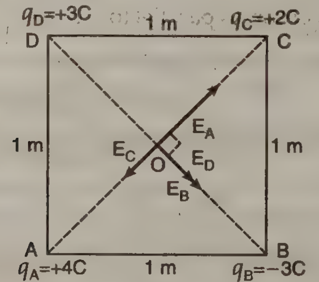

Fig. 2.01

Then, $\sqrt{r^2 + r^2} = 1 \quad \text{or} \quad r = \frac{1}{\sqrt{2}}$ m

Also, $\frac{1}{4\pi\varepsilon_0} = \frac{1}{4\pi \times 8{\cdot}85 \times 10^{-12}}$

$$= 9 \times 10^9\ \text{C}^2\,\text{N}^{-1}\,\text{m}^{-2}$$

Now, $E_A = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A}{r^2} = 9 \times 10^9\ \frac{4}{(1/\sqrt{2})^2}$

$= 72 \times 10^9$ N (along OC)

$E_B = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_B}{r^2} = 9 \times 10^9\ \frac{3}{(1/\sqrt{2})^2}$

$= 54 \times 10^9$ N (along OB)

$E_C = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_C}{r^2} = 9 \times 10^9\ \frac{2}{(1/\sqrt{2})^2}$

$= 36 \times 10^9$ N (along OA)

$E_D = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_D}{r^2} = 9 \times 10^9\ \frac{3}{(1/\sqrt{2})^2}$

$= 54 \times 10^9$ N (along OB)

Since $E_A > E_C$, the resultant E_A and E_C acts along OC and iven by

$$E_1 = E_A - E_C = 72 \times 10^9 - 36 \times 10^9 = 36 \times 10^9 \text{ N} \quad \text{(along OC)}$$

The resultant of E_B and E_D is given by

$$E_2 = E_B + E_D = 54 \times 10^9 + 54 \times 10^9 = 108 \times 10^9 \text{ N} \quad \text{(along OB)}$$

The two electric fields E_1 and E_2 have been separately wn in Fig. 2.02.

The two fields are inclined at $\theta = 90°$. Therefore, their ultant is given by

$$E = \sqrt{{E_1}^2 + {E_2}^2}$$

$$= \sqrt{(36 \times 10^9)^2 + (108 \times 10^9)^2} \quad \text{(along OB)}$$

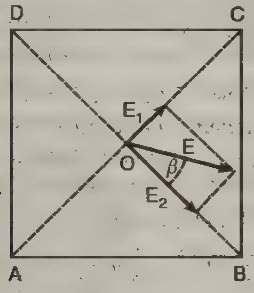

Fig. 2.02.

$$= 36 \times 10^9 \sqrt{1+9} = 1{\cdot}138 \times 10^{11} \text{ N C}^{-1}$$

Suppose that the resultant electric field E makes an angle ith theline OB. Then,

$$\tan\beta = \frac{E_1}{E_2} = \frac{36 \times 10^9}{108 \times 10^9} = 0{\cdot}3333$$

or $\beta = 18{\cdot}43$ (with OB)

Problem 2.02. A point particle of mass M is attached ne end of a massless rigid non conducting rod of length Another point particle of the same mass is attached to the er end of the rod. The two particles carry charges $+q$ and respectively. This arrangement is held in the region of iform electric field E, such that the rod makes a small gle θ (say about 5°) with the field direction [Fig. 2.03]. d an expression for the minimum time needed for the to become parallel to the field after it is set free. *(I.I.T. 1989)*

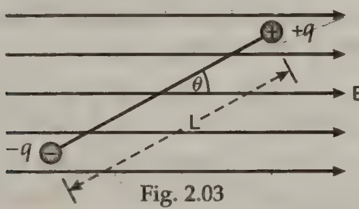

Fig. 2.03

ought Process

1. *The two equal and opposite charges at its two ends of the rod form an electric dipole.*
2. *The system executes S.H.M. under the effect of the torque due to electric field.*
3. *Required time* $= \frac{1}{4} \times$ *time period of S.H.M.*

Sol. The rod AB carrying two particles of charges q and $-q$ at the ends A and B and of mass M each has been placed in electric field, such that it makes a small angle θ with the direction of the field.

The force q E acts on the two particles at points A and B along and opposite to the direction of the electric field as shown in Fig. 2.04.

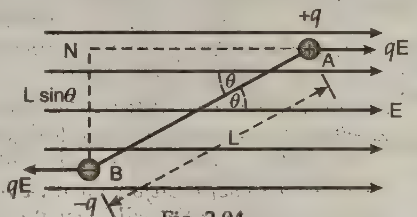

Fig. 2.04

Since the two forces are equal in magnitude and opposite in direction, the two forces consitiute a torque.

The magnitude of torque is given by

$$\tau = q\,\text{E} \times \text{BN} = q\,\text{E L} \sin\theta$$

Since θ is small, $\sin\theta \approx \theta$

$$\therefore \quad \tau = q\,\text{E L}\,\theta$$

The torque acting on the system tends to rotate it in the electric field. If I is moment of inertia of the system and α, the angular acceleration produced, then

$$\tau = \text{I}\alpha$$

In equilibrium,

$$\text{I}\alpha = q\,\text{E L}\,\theta$$

$$\text{or} \quad \alpha = \frac{q\,\text{E L}}{\text{I}}\,\theta \quad \text{or} \quad \alpha \propto \theta$$

Therefore, the motion executed by the system is S.H.M. and its time period is given by

$$\text{T} = 2\pi\sqrt{\frac{\theta}{\alpha}} = 2\pi\sqrt{\frac{\text{I}}{q\,\text{E L}}}$$

Moment of inertia of the system about an axis, which is right bisector of the rod AB is given by

$$\text{I} = 2\pi\left(\frac{\text{L}}{2}\right)^2 + \text{M}\left(\frac{\text{L}}{2}\right)^2 = \frac{1}{2}\text{M L}^2$$

$$\therefore \quad \text{T} = 2\pi\sqrt{\frac{\frac{1}{2}\text{M L}^2}{q\,\text{E L}}} = 2\pi\sqrt{\frac{\text{M L}}{2q\,\text{E}}}$$

The rod becomes parallel to the direction of electric field after executing one fourth of its one vibration *i.e.* in a time $\frac{\text{T}}{4}$.

$$\text{Therefore, required time, } \frac{\text{T}}{4} = \frac{\pi}{2}\sqrt{\frac{\text{M L}}{2q\,\text{E}}}$$

Chapter 3. Electric Potential

Problem 3.01. A charge Q is distributed over two ncentric hollow spheres of radii r and R (when (R > r), such that the surface densities are equal. Find the potential at the common centre. *(I.I.T. 1981)*

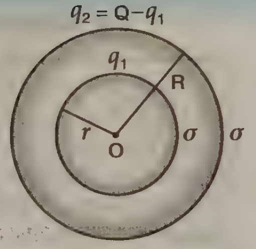

Fig. 3.01

Sol. Fig 3.01 shows two concentric hollow spheres of radii r and R, such that $R > r$.

A total charge Ω is distributed over the two hollow spheres, so that the surface densities of the two spheres are equal. If charge q_1 is distributed over the smaller sphere and q_2 over the larger sphere, then

$$q_1 + q_2 = Q \quad \text{...}(i)$$

If σ is the surface charge density of the two spheres, then

$$\sigma = \frac{q_1}{4\pi r^2} = \frac{q_2}{4\pi R^2}$$

or $\quad q_1 = 4\pi r^2 \sigma \quad$ or $\quad q_2 = 4\pi R^2 \sigma$

Substituting for q_1 and q_2 in equation (*i*), we have

$$4\pi r^2 \sigma + 4\pi R^2 \sigma = E$$

or $$\sigma = \frac{R}{4\pi (r^2 + R^2)}$$

$\therefore$ $$q_1 = 4\pi r^2 \times \frac{Q}{4\pi (r^2 + R^2)} = \frac{Q r^2}{r^2 + R^2}$$

and $$q_2 = 4\pi R^2 \times \frac{Q}{4\pi (r^2 + R^2)} = \frac{Q R^2}{r^2 + R^2}$$

The potential at a point inside the charged sphere is equal to the potential at its surface.

Therefore, the potential due to the smaller sphere at the common centre,

$$V_1 = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_1}{R} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{Q r}{(r^2 + R^2)}$$

Also, the potential due to the larger sphere at the common centre,

$$V_2 = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_2}{R} = \frac{1}{4\pi\varepsilon_0} \cdot \frac{Q R}{(r^2 + R^2)}$$

Therefore, total potential at the common centre,

$$V = V_1 + V_2$$
$$= \frac{1}{4\pi\varepsilon_0} \cdot \frac{Q r}{(r^2 + R^2)} + \frac{1}{4\pi\varepsilon_0} \cdot \frac{Q R}{(r^2 + R^2)}$$
$$= \frac{1}{4\pi\varepsilon_0} \frac{Q (r + R)}{(r^2 + R^2)}$$

Probelm 3.02 Three concentric spherical metal shells A, B and C of radii a, b and c ($a < b < c$)have surface charge densities $+\sigma$, $-\sigma$ and $+\sigma$ respectively.

(*i*) Find the potentials of three shells A , B and C.

(*ii*) If the shells A and C are at the same potential, obtain the relation between the radii a, b and c. (*I.I. T. 1990*)

Thought Process

1. The potential of any shell is due to its own charge and the charge on the other two shells.

2. In case of a charged metallic spherical shell or a sphere, (a) for a point outside the conductor, the charge appears to be concentrated at its centre and (b) for all the points inside the conductor, the potential is same every where and is equal to that at a point on its surface.

Sol. Fig 3.02 shows three concentric spherical metal shells A, B and C of radii a, b and c ($a < b < c$).

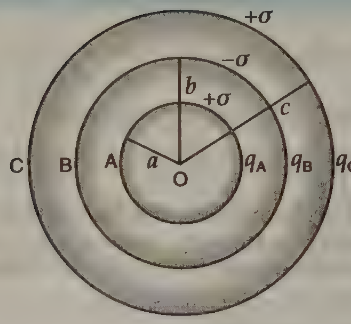

Fig. 3.02

Further, the surface charge densities of the shells A and C are $+\sigma$, $-\sigma$ and $+\sigma$ respectively. If q_A, q_B and q_C charges on the respective shells, then

$$q_A = 4\pi a^2 \sigma, \; q_B = -4\pi b^2 \sigma$$

and $$q_C = 4\pi c^2 \sigma$$

(*i*) Let V_A, V_B and V_C be potentials of the shells A and C.

Potential of shell A : A point on the surface of shell lies inside the shells B and C. Therefore,

$$V_A = \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_A}{a} + \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_B}{b} + \frac{1}{4\pi\varepsilon_0} \cdot \frac{q_C}{c}$$
$$= \frac{1}{4\pi\varepsilon_0} \left(\frac{4\pi a^2 \sigma}{a} - \frac{4\pi b^2 \sigma}{b} + \frac{4\pi c^2 \sigma}{c} \right)$$

or $$V_A = \frac{\sigma}{\varepsilon_0} (a - b - c)$$

Potential of shell B : A point on shell B lies outside shell A and inside the shell C. Therefore,

$$V_B = \frac{1}{4\pi\varepsilon_0} \left(\frac{q_A}{b} + \frac{q_B}{b} + \frac{q_C}{c} \right)$$
$$= \frac{1}{4\pi\varepsilon_0} \left(\frac{4\pi a^2 \sigma}{b} - \frac{4\pi b^2 \sigma}{b} + \frac{4\pi c^2 \sigma}{c} \right)$$
$$= \frac{\sigma}{\varepsilon_0} \left(\frac{a^2 - b^2}{b} + c \right)$$

Potential of shell C : A point on shell C lies outside the shells A and B. Therefore,

$$V_C = \frac{1}{4\pi\varepsilon_0} \left(\frac{q_A}{c} + \frac{q_B}{c} + \frac{q_C}{c} \right)$$
$$= \frac{1}{4\pi\varepsilon_0} \left(\frac{4\pi a^2 \sigma}{c} - \frac{4\pi b^2 \sigma}{c} + \frac{4\pi c^2 \sigma}{c} \right)$$

or $$V_C = \frac{\sigma}{\varepsilon_0} \left(\frac{a^2 - b^2 + c}{c} \right)$$

(*ii*) If the shells A and C are at the same potential,

$$V_A = V_C$$

or $$\frac{\sigma}{\varepsilon_0} (a - b + c) = \frac{\sigma}{\varepsilon_0} \left(\frac{a^2 - b^2 + c}{c} \right)$$

or $$(a-b+c)=\frac{a^2-b^2}{c}+c$$

or $$c\ (x-b)=a^2-b^2$$

or $$c=a+b$$

Problem 3.03. A drop of water of mass 18 × 10^{-3} falls ay from the bottom of charged conducting sphere of ius 20 cm, carrying with it a charge of 10^{-9} C and leaving the sphere a uniformly distributed charge of 2·5 × 10^{-6} C. at is the speed of the drop after it has fallen 30 cm ? $\varepsilon_0)^{-1} = 9 \times 10^9$ J m C^{-2}. *(Roorkee, 1985)*

Sol. The drop of water mass m and charge q leaves the ducting sphere of charge Q at point A and falls through istance of 30 cm up to point B [Fig. 3.03]. The drop acquires etic energy at point B at the expense of gravitational ential energy and the electrostatic potential energy. Let v the speed of the drop on reaching the point B. Since, rease in K.E. of drop is equal to decrease in electrostatic l gravitational potential energies, we have

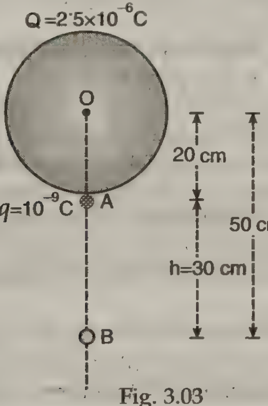

Fig. 3.03

$$\frac{1}{2}mv^2=\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{OA}-\frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{OB}\right)+mgh$$

$$=\frac{1}{4\pi\varepsilon_0}\cdot Qq\left(\frac{1}{OA}-\frac{1}{OB}\right)+mgh$$

Here, $h = 30$ cm $= 0{\cdot}3$ m ;

$m = 18 \times 10^{-3}$ g $= 18 \times 10^{-6}$ kg ;

$Q = 2{\cdot}5 \times 10^{-6}$ C ; $q = 10^{-9}$ C,

OA = radius of sphere = 20 cm = 0·2 m ;

OB = 20 + 30 = 50 cm = 0·5 m

$$\therefore\ \frac{1}{2}\times 18\times 10^{-6}\ v^2$$

$$=9\times 10^9\times 2{\cdot}5\times 10^{-6}\times 10^{-9}\times\left(\frac{1}{0{\cdot}2}-\frac{1}{0{\cdot}5}\right)$$

$$+\ 18\times 10^{-6}\times 9{\cdot}8\times 0{\cdot}3$$

$$9\times 10^{-6}\ v^2$$

$$=9\times 2{\cdot}5\times 10^{-6}\ (5-2)+18\times 10^{-6}\times 9{\cdot}8\times 0{\cdot}3$$

$$=67{\cdot}5\times 10^{-6}+52{\cdot}92\times 10^{-6}$$

or $$v^2=\frac{67{\cdot}5+52{\cdot}92}{9}=13{\cdot}38$$

or $$v = 3{\cdot}66\ \text{m s}^{-1}$$

Problem 3.04. Three charges of + 0·1 C each are placed he vertices of an equilateral triangle of each side 1 m. If the energy is supplied at the rate of 1·0 kW, how many hours would be required to move one of the charges on to the mid point of the line joining the other two ?

Given, $$\frac{1}{4\pi\varepsilon_0}=9\times 10^9\ \text{N m}^2\ \text{C}^{-2}.$$

(I.S.M. Dhanbad, 1991)

Thought Process

Work done in moving one of the charges on to the mid point of the line joining the other two charges is equal to the increase in electrostatic potential energy of the system.

Sol. Three charges q_A and q_C, each of 0·1 C are placed at the vertices of the equilateral triangle ABC of each side 1 m as shown in Fig 3.04.

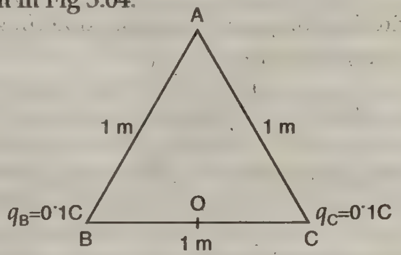

Fig. 3.04

The initial potential energy of the configuration of three charges,

$$U_1=\frac{1}{4\pi\varepsilon_0}\left(\frac{q_A\,q_B}{AB}+\frac{q_B\,q_C}{BC}+\frac{q_C\,q_A}{CA}\right)$$

Since $q_A = q_B = q_C = 0{\cdot}1$ C

and AB = BC = CA = 1 m, we have

$$U_1=9\times 10^9\left(\frac{0{\cdot}1\times 0{\cdot}1}{1}+\frac{0{\cdot}1\times 0{\cdot}1}{1}+\frac{0{\cdot}1\times 0{\cdot}1}{1}\right)$$

$$=27\times 10^7\ \text{J}$$

Suppose the charge q_A is moved from the vertex A to the mid point O of the line AB. Then, the final potential energy of the configuration of three charges,

$$U_2=\frac{1}{4\pi\varepsilon_0}\left(\frac{q_A\,q_B}{OB}+\frac{q_B\,q_C}{OC}+\frac{q_B\,q_C}{BC}\right)$$

Now, $$OB = OC = \frac{AB}{2}=0{\cdot}5\ \text{m}$$

$$U_2=9\times 10^9\left(\frac{0{\cdot}1\times 0{\cdot}1}{0{\cdot}5}+\frac{0{\cdot}1\times 0{\cdot}1}{0{\cdot}5}+\frac{0{\cdot}1\times 0{\cdot}1}{0{\cdot}5}\right)$$

$$=45\times 10^7\ \text{J}$$

Work done to move the charge q_A from point A to O,

$$W = U_2 - U_1 = 45\times 10^7 - 27\times 10^7 = 18\times 10^7\ \text{J}$$

Since energy is supplied at the rate of 1·0 kW *i.e.* 10^3 J s^{-1}, the time required to move the charge q_A from point A to O,

$$t=\frac{18\times 10^7}{10^3}=18\times 10^4\ \text{s}=\frac{18\times 10^4}{3600}=50\ \text{h}$$

Problem 3.05. Three charges each of value q are placed at the corners of an equilateral triangle. A fourth charge Q is placed at the centre of the triangle.

(*i*) If Q = – q, will the charges at the corners move towards the centre or fly away from it ?

(ii) For what value of Q, will the charges remain stationary ? In this situation, how much work is done in removing the charges to infinity ? (*I.I.T. 1978*)

Sol. (*i*) Consider that three charges each of value q are placed at the corners of an equilateral triangle ABC of each side of length r as shown in Fig. 3.05.

When the charge Q placed at the centre of the triangle is $-q$, the three charges at the corners of the triangle experience attractive forces due to the charge $-q$ placed at centre. Therefore, ***all the charges will move towards the centre of the triangle.***

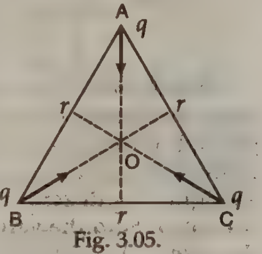

Fig. 3.05.

It may be pointed out that it is the charge at the centre, which experiences zero net force due to charges at the corners. The charge at each corner experiences an unbalanced force due to the charge at centre.

(*ii*) The charge at the centre of the triangle will be in equilibrium irrespective of its magnitude and sign. But a charge at the corner can be in equilibrium only if charge at the centre is negative and has a definite magnitude. Suppose that when a charge $-Q$ is placed at the centre of the triangle, all the charges are in equilibrium. Consider the charge q at point A. It experiences forces F_B, F_C and F_O due to charges lying at points B, C and O as shown in Fig. 3.06.

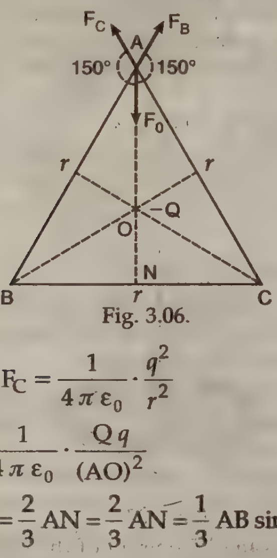

Fig. 3.06.

Now, $$F_B = F_C = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{r^2}$$

and $$F_O = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Qq}{(AO)^2}$$

Now, $$AO = \frac{2}{3}AN = \frac{2}{3}AN = \frac{1}{3}AB\sin 60°$$

$$= \frac{2}{3}\times r\times\frac{\sqrt{3}}{2}\;\frac{r}{\sqrt{3}}$$

$$\therefore \quad F_O = \frac{1}{4\pi\varepsilon_0}\cdot\frac{3Qq}{r^2}$$

For the charge q at point A to be in equilibrium,

$$\frac{F_B}{\sin 150°} = \frac{F_C}{\sin 150°} = \frac{F_O}{\sin 60°} \quad \text{(Lami's theorem)}$$

or $$F_O = F_C\times\frac{\sin 60°}{\sin 30°} = \sqrt{3}\,F_C$$

$(\because \sin 150° = \sin 30°)$

or $$\frac{1}{4\pi\varepsilon_0}\cdot\frac{3Qq}{r^2} = \sqrt{3} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q^2}{r^2}$$

or $$Q = \frac{q}{\sqrt{3}} \qquad \text{(magnitud}$$

As said above, the charge at the centre of the triangle ha to be negative.

Therefore, $Q = -\dfrac{q}{\sqrt{3}}$

The potential energy of the system in its present stat

$$U_1 = \frac{1}{4\pi\varepsilon_0}\left(\frac{qq}{AB}+\frac{qq}{BC}+\frac{qq}{CA}+\frac{q(-q/\sqrt{3})}{AO}\right.$$
$$\left.+\frac{q(-q/\sqrt{3})}{BO}+\frac{q(-q/\sqrt{3})}{CO}\right.$$

$$= \frac{1}{4\pi\varepsilon_0}q^2\left(\frac{1}{r}+\frac{1}{r}+\frac{1}{r}-\frac{1}{\sqrt{3}(r/\sqrt{3})}\right.$$
$$\left.-\frac{1}{\sqrt{3}(r/\sqrt{3})}-\frac{1}{\sqrt{3}(r/\sqrt{3})}\right) =$$

When all the charges are removed to infinity, th potential energy of the system, $U_2 = 0$

Therefore, work done to remove the charges to infinit

$$W = U_1 - U_2 = 0 - 0 = 0$$

Problem 3.06. A conducting sphere S_1 of radius attached to an insulating handle. Another conductin sphere S_2 of radius R is mounted on an insulating stan S_2 is initially uncharged. S_1 is given a charge Q, broug into contact with S_2, and removed. S_1 is recharged such th the charge on it is again Q ; and it is again brought in contact with S_2 and removed. This procedure is repeate *n* times.

(*a*) Find the electrostatic energy of S_2 after *n* suc contacts with S_1.

(*b*) What is the limiting value of this energy as $n \to \infty$

(*I.I.T. 199*

Sol. (*a*) ***After first contact*** : Suppose that the sphere acquires charge q_1 after it is brought in contact with sphe having charge Q. Then, the charge left on sphere S_1 will $Q - q_1$. As the two spheres are conducting, the charg redistribute on them so that their potentials become th same *i.e.*

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{Q-q_1}{r} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1}{R}$$

or $$\frac{Q}{r} = \frac{q_1}{r}+\frac{q_1}{R} = \frac{q_1(R+r)}{rR}$$

or $$q_1 = \frac{QR}{R+r}$$

After second contact : The sphere S_1 is recharged, so to have charge Q again. The sphere S_2 is having charge q_1, that the total charge on the two spheres is $Q+q_1$. Suppose th when the sphere S_2 is removed, the charge on S_2 becomes Then,

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{(Q+q_1)-q_2}{r} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_2}{R}$$

or $$\frac{Q}{r}+\frac{q_1}{r} = \frac{q_2}{r}+\frac{q_2}{R}$$

or $$\frac{1}{r}(Q+q_1) = q_2\left(\frac{1}{r}+\frac{1}{R}\right) = \frac{q_2(R+r)}{rR}$$

or
$$q_2 = \frac{R}{R+r}(Q+q_1)$$

Substituting the value of q_1, we have

or
$$q_2 = \frac{R}{R+r}\left(Q+\frac{QR}{R+r}\right)$$
$$= \frac{QR}{R+r}\left(1+\frac{R}{R+r}\right)$$

After third contact: Charge q_3 on the sphere S_2 after third act is given by

$$\frac{1}{4\pi\varepsilon_0}\cdot\frac{(Q+q_2)-q_3}{r} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_3}{R}$$

or
$$\frac{Q}{r}+\frac{q_2}{r} = \frac{q_3}{r}+\frac{q_3}{R}$$

or
$$\frac{1}{r}(Q+q_2) = q_3\left(\frac{1}{r}+\frac{1}{R}\right) = \frac{q_3(R+r)}{rR}$$

or
$$q_3 = \frac{R}{R+r}(Q+q_2)$$

Substituting the value of q_2, we obtain

$$q_3 = \frac{R}{R+r}\left[Q+\frac{QR}{R+r}\left(1+\frac{R}{R+r}\right)\right]$$

or
$$= \frac{QR}{R+r}\left[1+\left(\frac{QR}{R+r}\right)+\left(\frac{R}{R+r}\right)^2\right]$$

It follows that charge on the sphere S_2 after nth contact be

$$q_n = \frac{QR}{R+r}\left[1+\left(\frac{R}{R+r}\right)+\left(\frac{R}{R+r}\right)^2 + \dots\dots\dots + \left(\frac{R}{R+r}\right)^{n-1}\right]$$

It is a G.P. having first term = 1, common ratio $\frac{R}{R+r}$ and ber of terms equal to n.

∴
$$q_n = \frac{QR}{R+r}\left[\frac{1-\left(\frac{R}{R+r}\right)^n}{1-\left(\frac{R}{R+r}\right)^n}\right]$$
$$= \frac{QR}{r}\left[1-\left(\frac{R}{R+r}\right)^n\right]$$

The energy stored in the sphere S_2 after n contacts,

$$U = \frac{1}{2}\frac{q_n^2}{C},$$

re $C = 4\pi\varepsilon_0 R$ is the capacitance of the sphere S_2.

$$\therefore\quad U = \frac{1}{2}\times\frac{1}{4\pi\varepsilon_0 R}\times\left(\frac{QR}{r}\right)^2\left[1-\left(\frac{R}{R+r}\right)^n\right]^2$$
$$= \frac{Q^2 R}{8\pi\varepsilon_0 r^2}\left[1-\left(\frac{R}{R+r}\right)^n\right]^2$$

(b) When $n \to \infty$:

$$\therefore\quad \underset{n\to\infty}{\text{Lt}}\ U = \underset{n\to\infty}{\text{Lt}}\ \frac{Q^2 R}{8\pi\varepsilon_0 r^2}\left[1-\left(\frac{R}{R+r}\right)^n\right]^2$$
$$= \frac{Q^2 R}{8\pi\varepsilon_0 r^2}[1-0]^2 = \frac{Q^2 R}{8\pi\varepsilon_0 r^2}$$

Problem 3.07. A non-conducting disc of radius a and uniform positive surface charge density σ is placed on the ground, with its axis vertical. A particle of mass m and positive charge q is dropped along the axis of the disc from a height H with zero initial velocity. The particle has $q/m = 4\pi\varepsilon_0/\sigma$. Find the value of H, if the particle just reaches the disc. (I.I.T. 1999)

Thought Process

1. When the charge is at a height H above the disc, it possesses both electrostatic potential energy and gravitational potential energy.

2. When the charge just reaches the disc, it possesses only electrostatic potential energy.

From the principle of conservation of energy, potential energy (electrostatic + gravitational) of the particle at height H = electrostatic potential energy of the particle at the disc.

Sol. Fig. 3.07 shows the non conducting disc of radius a and centre O having surface charge density σ. The particle of mass m and charge q is dropped from point P.

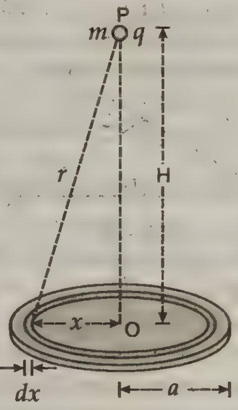

Fig. 3.07

Gravitational potential energy of the particle, when at point P,

$$U_1 = m\,g\,H \qquad \dots(i)$$

Let U_2 be electrostatic potential energy of the particle, when at point P. If V is electrostatic potential due to the charged disc at point P, then

$$U_2 = V\,q$$

To find V. In order to find V, consider a small portion of the disc between two concentric circles of radii x and $x + dx$. If dq is charge on the elementary portion, then potential at point P due to the elementary portion,

$$dV = \frac{1}{4\pi\varepsilon_0}\cdot\frac{dq}{r}$$

Now, $dq = (2\pi x\,dx)\,\sigma = 2\pi\sigma x\,dx$;

$r = (H^2 + x^2)^{1/2}$

$$\therefore \quad dV = \frac{1}{4\pi\varepsilon_0}\cdot\frac{2\pi\sigma x}{(H^2+x^2)^{1/2}}\,dx$$

$$= \frac{\sigma}{2\varepsilon_0}\cdot\frac{x}{(H^2+x^2)^{1/2}}\,dx$$

The potential at point P due to the whole disc can be found by integrating the above within the limits $x = 0$ to $x = a$ *i.e.*

$$V = \frac{\sigma}{2\varepsilon_0}\int_0^a \frac{x}{(H^2+x^2)^{1/2}}\,dx$$

Put $H^2 + x^2 = z$

Then, $2x\,dx = dz$ or $x\,dx = \frac{1}{2}dz$

The limits of integration corresponding to $x = 0$ and $x = a$ now become $z = H^2$ and $z = H^2 + a^2$ respectively.

$$\therefore \ V = \frac{\sigma}{2\varepsilon_0}\int_{H^2}^{H^2+a^2}\frac{\frac{1}{2}dz}{z^{1/2}} = \frac{\sigma}{4\varepsilon_0}\int_{H^2}^{H^2+a^2} z^{-1/2}\,dz$$

$$= \frac{\sigma}{4\varepsilon_0}\left|\frac{z^{1/2}}{\frac{1}{2}}\right|_{H^2}^{H^2+a^2} = \frac{\sigma}{2\varepsilon_0}\left(\sqrt{H^2+a^2} - H\right)$$

Therefore, total energy of the particle, when at point P,

$$U = U_1 + U_2 = m\,g\,H + V\,q$$

$$= m\,g\,H + \frac{q\sigma}{2\varepsilon_0}\left(\sqrt{H^2+a^2} - H\right) \qquad ...(i)$$

The energy of the particle, when it reaches the disc, can be found by setting $H = 0$ in the above equation. Thus, energy of the particle, when it reaches the disc,

$$U' = 0 + \frac{q\sigma}{2\varepsilon_0}\left(\sqrt{0^2+a^2} - 0\right) = \frac{q\sigma a}{2\varepsilon_0} \qquad ...(ii)$$

From the principle of conservation of energy, we have

$$U = U'$$

$$\text{or} \quad m\,g\,H = \frac{q\sigma}{2\varepsilon_0}\left(\sqrt{H^2+a^2} - H\right) = \frac{q\sigma a}{2\varepsilon_0} \qquad ...(iii)$$

Now, $\frac{q}{m} = \frac{4\varepsilon_0\,g}{\sigma}$ or $m = \frac{q\sigma}{4\varepsilon_0\,g}$

Substituting for m in equation (*iii*), we have

$$\frac{q\sigma}{4\varepsilon_0\,g}\,g\,H + \frac{q\sigma}{2\varepsilon_0}\left(\sqrt{H^2+a^2} - H\right) = \frac{q\sigma a}{2\varepsilon_0}$$

$$\text{or} \quad \frac{H}{2} + \left(\sqrt{H^2+a^2} - H\right) = a$$

$$\text{or} \quad \sqrt{H^2+a^2} = \left(a + \frac{H}{2}\right)$$

$$\text{or} \quad H^2 + a^2 = \left(a + \frac{H}{2}\right)^2$$

$$\text{or} \quad H = \frac{4}{3}a$$

Problem 3.08. Three charges q, 2 q and 8 q are to be placed on a 9 cm long straight line. Find the positions, where the charges should be placed, such that the potential energy of this system is minimum. In this situation, what is the electric field at the position of the charge q due to th other two charges ? (*I.I.T. 198*

Sol. Consider that the three charges q, 2 q and 8 q ar placed at points A, B and C on a line AC = 9 cm = 0·09 m a shown in Fig. 3.08.

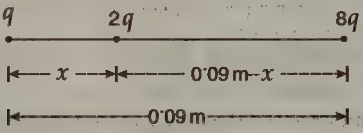

Fig. 3.08.

Suppose that AB = x.

Then, BC = 0·09 − x

The electrostatic potential energy of the system of thre charges is given by

$$U = \frac{1}{4\pi\varepsilon_0}\left(\frac{q\times 2q}{AB} + \frac{q\times 8q}{AC} + \frac{2q\times 8q}{BC}\right)$$

$$\text{or} \quad U = \frac{q^2}{2\pi\varepsilon_0}\left(\frac{1}{x} + \frac{4}{0\cdot 09} + \frac{8}{(0\cdot 09 - x)}\right) \qquad ...(i)$$

For the positions of the three charges shown in the figur potential energy of the system will be minimum, if $\frac{dU}{dx} = 0$

Differentiating both sides of equation (*i*) *w.r.t.* x, we hav

$$\frac{dU}{dx} = \frac{q^2}{2\pi\varepsilon_0}\left(-\frac{1}{x^2} + 0 - \frac{8}{(0\cdot 09 - x)^2}(-1)\right)$$

$$= \frac{q^2}{2\pi\varepsilon_0}\left(\frac{8}{(0\cdot 09 - x)^2} - \frac{1}{x^2}\right)$$

Since U is minimum, $\frac{dU}{dx} = 0$

$$\text{i.e.} \quad \frac{q^2}{2\pi\varepsilon_0}\left(\frac{8}{(0\cdot 09 - x)^2} - \frac{1}{x^2}\right) = 0$$

$$\text{or} \quad \frac{8}{(0\cdot 09 - x)^2} = \frac{1}{x^2}$$

$$\text{or} \quad (0\cdot 09 - x)^2 = 8x^2$$

$$\text{or} \quad 0\cdot 09 - x = 2\sqrt{2}\,x$$

$$\text{or} \quad (1 + 2\sqrt{2})\,x = 0\cdot 09$$

$$\text{or} \quad x = 0\cdot 0235 \text{ m} = 2\cdot 35 \text{ cm}$$

Therefore, potential energy of the system of three charg will be minimum, if the charge 2 q is placed at a distance 2·35 cm from the charge q and 9 − 2·35 *i.e.* 6·65 cm from th charge 8 q.

The electric field at the location of charge q will be th resultant of the electric fields E_B and E_C due to charges 2 q an 8 q located at points B and C respectively. Since both the field will be along CA, the resultant electric field at point A is give by

$$E = E_B = E_C = \frac{1}{4\pi\varepsilon_0}\left(\frac{2q}{AB^2} + \frac{8q}{AC^2}\right)$$

$$= 9\times 10^9 \times 2q\left(\frac{1}{(0\cdot 0235)^2} + \frac{4}{(0\cdot 09)^2}\right)$$

$$= 9 \times 10^9 \times 2\,q\,(1810{\cdot}8 + 493{\cdot}8)$$

$$= 4{\cdot}15 \times 10^{13}\,q\ \text{N C}^{-1}$$

roblem 3.09. Two fixed equal positive charges each agnitude 5×10^{-5} are located at points A and B rated by a distance of 6 m. An equal and opposite e moves towards them along the line COD, the endicular bisector of the line AB [Fig. 3.09]. The ng charge, when it reaches the point C at a distance of rom O, has a kinetic energy of 4 J. Calculate the nce of the farthest point D, which the negative charge each before returning towards C. (*I.I.T. 1985*)

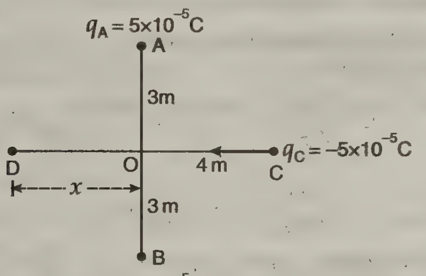

Fig. 3.09.

ught Process

At point C, the charge – q possesses electrostatic potential energy and kinetic energy. It will go up to that farthest point D, where its total energy is in the form of potential energy.

ol. The two charges q_A and q_B each of 5×10^{-5} C are d at the points A and B, such that AB = 6 m. A charge -5×10^{-5} C moves along the bisector COD of the line

At point C, the charge q_C possesses potential energy in ion to the kinetic energy of 4 J.

Now, potential energy of charge of -5×10^{-5} C at the C,

$$U_1 = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_C\,q_A}{AC} + \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_C\,q_B}{BC}$$

ince $q_A = q_B = 5 \times 10^{-5}$ C ; $q_C = -5 \times 10^{-5}$ C

nd $AC = BC\sqrt{3^2 + 4^2} = 5$ m, we have

$$U = 9\times10^9 \times \frac{(-5\times10^{-5})\times(5\times10^{-5})}{5}$$

$$+9\times10^9 \times \frac{(-5\times10^{-5})\times(5\times10^{5})}{5}$$

$$= -4{\cdot}5 - 4{\cdot}5 = -9\ \text{J}$$

otal energy of the charge q_C at point C,

E = U + kinetic energy of the charge at point C

$$= -9 + 4 = -5\ \text{J}$$

he charge q_C can move upto a farthest point D, where tential energy will become equal to the total energy of t point C.

Potential energy of charge q_C, when at point D,

$$U' = 9\times10^9 \times \frac{(-5\times10^{-5})\times(5\times10^{5})}{DA}$$

$$+9\times10^9 \times \frac{(-5\times10^{-5})\times(5\times10^{5})}{DB}$$

$$= -22{\cdot}5\left(\frac{1}{DA} + \frac{1}{DB}\right)$$

Suppose that the distance of point D from O is x. Then,

$$DA = DB = \sqrt{3^2 + x^2} = \sqrt{9 + x^2}$$

$$\therefore\ U' = -22{\cdot}5\left(\frac{1}{\sqrt{9+x^2}} + \frac{1}{\sqrt{9+x^2}}\right) = -\frac{45}{\sqrt{9+x^2}}$$

Since U′ = E, we have

$$\text{or}\quad -\frac{45}{\sqrt{9+x^2}} = -5 \qquad \text{or}\quad \sqrt{9+x^2} = 9$$

$$\text{or}\quad x = 8{\cdot}49\ \text{m}$$

Problem 3.10. A particle of mass 40 mg and carrying a charge 5×10^{-9} C is moving directly towards a fixed positive point charge of magnitude 10^{-8} C. When it is at a distance of 10 cm from the fixed positive point, it has a velocity of 50 cm s^{-1}. At what distance from the fixed point charge, will the particle come momentarily to rest ? Is the acceleration constant during motion ? (*I.I.T. 1975*)

Hint. This problem is similar to the problem 3.09.

Suppose that the charged particle momentarily comes to rest, when its distance from the fixed charge is r.

Then, P.E. of the system at separation r is equal to the sum of the P.E. of the system at 10 cm separation and the kinetic energy of the moving charge.

Problem 3.11. (*a*) A charge Q coulomb is uniformly distributed over a sphere volume of radius R metres. Obtain an expression for the energy of the system.

(*b*) What will be the corresponding expressions for the energy needed to completely deassemble the planet each against the gravitational pull amongst its constituent particles ? Assume the earth to be a sphere of uniform mass density. Calculate this energy, given that the product of mass and the radius of the earth to be $2{\cdot}5 \times 10^{-31}$ kg m.

(*c*) If the same charge of Q coulomb as in part (*a*) above is given to a spherical conductor of the same radius R, what will be the energy of the system ? (*I.I.T. 1992*)

Sol. (*a*) Consider a sphere of radius R. The charge Q is uniformly distributed over its volume [Fig. 3.10]. If ρ is volume charge density, then

$$\rho = \frac{Q}{\frac{4}{3}\pi R^3}$$

The sphere of volume charge density ρ may be assumed to be built by putting the spherical layers of increasing radii around the initial spherical core, till a sphere of radius R is formed.

Suppose that at any instant, there is a spherical core of radius x as shown in the figure.

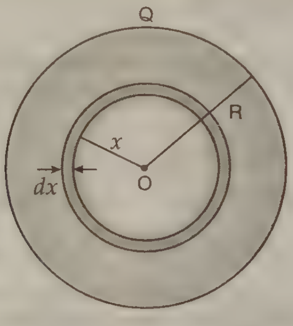

Fig. 3.10.

Then, charge on the spherical core, $q = \frac{4}{3}\pi x^3 \rho$

Suppose a spherical layer of infinitesimally small thickness dx having charge density ρ is put around the spherical core. The small amount of charge on the spherical layer,

dq = volume of the layer $\times \rho = (4\pi x^2 dx)\rho$

The system of the charged spherical core (of radius x) and the charged spherical layer (of thickness dx) possess electrostatic potential energy, which is given by

$$dU = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q\,dq}{x} = \frac{1}{4\pi\varepsilon_0}\cdot\frac{\frac{4}{3}\pi x^3\rho\times(4\pi x^2\,dx)\rho}{x}$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{16}{3}\pi^2\rho^2 x^4\,dx$$

Therefore, electrostatic energy of the sphere of radius R is given by

$$U = \int_0^R dU = \frac{1}{4\pi\varepsilon_0}\cdot\frac{16}{3}\pi^2\rho^2\int_0^R x^4\,dx$$

$$= \frac{1}{4\pi\varepsilon_0}\cdot\frac{16}{3}\pi^2\rho^2\left|\frac{x^5}{5}\right|_0^R = \frac{1}{4\pi\varepsilon_0}\cdot\frac{16}{3}\pi^2\rho^2\frac{R^5}{5}$$

Substituting for ρ, we have

$$U = \frac{1}{4\pi\varepsilon_0}\cdot\frac{16}{3}\pi^2\left(\frac{Q}{\frac{4}{3}\pi R^3}\right)^2 = \frac{R^5}{5} = \frac{3}{5}\cdot\frac{Q}{4\pi\varepsilon_0 R}$$

(*b*) In expression for gravitational potential energy,

constant $\frac{1}{4\pi\varepsilon_0}$ and Q get replaced by gravitational consta

G and mass M of the earth. In addition to it, the gravitatio potential energy is negative (gravitational force is attract in nature). Therefore,

Gravitational energy of the earth, $U = -\frac{3}{5}\cdot\frac{GM^2}{R}$

Here, R is radius of the earth.

The energy needed to completely deassemble the ea amongst its constituent particles will be

$$W = 0 - U = -U = -\frac{3}{5}\cdot\frac{GM^2}{R}$$

Now, $g = \frac{GM}{R}$

or $GM = gR^2$

$$\therefore \quad W = \frac{3}{5}\cdot\frac{gR^2\times M}{R} = \frac{3}{5}gMR$$

Here, $MR = 2.5\times10^{31}$ kg m and $g = 9.8\times$ m s^{-2}

$$\therefore \quad W = \frac{3}{5}\times 9.8\times 2.5\times 10^{31} = 1.47\times 10^{32}\ \text{J}$$

(*c*) In case, the same charge Q is given to a spheri conductor of radius R, the whole of the charge will app on its outer surface. Then,

Potential of the spherical conductor, $V = \frac{1}{4\pi\varepsilon_0}\cdot\frac{Q}{R}$

Further, the capacitance of the spherical conductor,

$C = 4\pi\varepsilon_0 R$

Therefore, energy stored in the spherical conductor,

$$U = \frac{1}{2}CV^2 = \frac{1}{2}\times 4\pi\varepsilon_0 R\times\left(\frac{1}{4\pi\varepsilon_0}\cdot\frac{Q}{R}\right)^2 = \frac{1}{2}\frac{Q}{4\pi\varepsilon_0 R}$$

Chapter 4. Gauss's Theorem

Problem 4.01. It has been experimentally observed that the electric field in a large region of earth's atmospher directed vertically down. At an altitude of 300 m, the electric field is 60 V m^{-1} and at an altitude of 200 m, the field is 100 V m^{-1}. Calculate the net amount of charge contained in a cube of each side of 100 m located between 200 m and 300 m altitude.

Sol. Fig. 4.01 shows a cube of each side 100 m located between 200 m and 300 m altitude. Therefore, area of each of the six faces of the cube,

$$A = 100\times100 = 10^4\ \text{m}^2$$

The electric fields $\vec{E}_1$ and $\vec{E}_2$ at the top and bottom face of the cube are directed along negative Z-axis. Therefore,

$$\vec{E}_1 = -60\,\hat{k}\ \text{V m}^{-1} \quad \text{and} \quad \vec{E}_2 = -100\,\hat{k}\ \text{V m}^{-1}$$

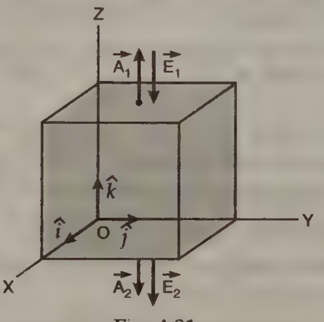

Fig. 4.01

The electric field $\vec{E}_1$ or $\vec{E}_2$ is parallel to the four verti faces of the cube. Therefore, no electric flux crosses throu four faces. If q is charge enclosed by the cube, then ing to Gauss's theorem, electric flux through the cube,

$$\Phi = \vec{E_1}\cdot\vec{A_1} + \vec{E_2}\cdot\vec{A_2}$$

r $\frac{q}{\varepsilon_0} = \vec{E_1}\cdot\vec{A_1} + \vec{E_2}\cdot\vec{A_2}$ ...(*i*)

$\vec{A_1}$ and $\vec{A_2}$ are the area vectors representing the area and bottom face of the cube respectively as shown in ure.

Iow, $\vec{A_1} = 10^4\,\hat{k}\,m^2$ and $\vec{A_2} = -10^4\,\hat{k}\,m^2$

ubstituting for $\vec{E_1}$, $\vec{E_2}$, $\vec{A_1}$ and $\vec{A_2}$ in equation (*i*), we

$$\frac{q}{\varepsilon_0} = (-60\,\hat{k})\cdot 10^4\,\hat{k} + (-100\,\hat{k})\cdot(-10^4\,\hat{k})$$

$$= -6\times10^5 + 10\times10^5 = 4\times10^5$$

r $q = \varepsilon_0 \times 4\times10^5 = 8{\cdot}854\times10^{-12}\times4\times10^5$

$= \mathbf{3{\cdot}542\times10^{-6}\ C}$

roblem 4.02. A conducting sphere of radius 10 cm has known charge. If the electric field 20 cm from the of the sphere is $1{\cdot}5\times10^3$ N C^{-1} and points radially ds, what is the net charge on the sphere ?

ol. Consider a sphere of radius R (= 10 cm) and centre charge on the conductor be q. Further, take a point P listance r = 20 cm from the centre of the sphere [Fig.

he electric field E (= $1{\cdot}5\times10^3$ N C^{-1}) is directed radially ds as shown in the figure. So as to enclose the charged sphere, draw a sphere (gaussian surface) with O as centre and r (= OP = 20 cm) as radius. As the electric field is radial, it is normal to the gaussian surface everywhere. Therefore,

electric flux through the gaussian surface,

$\Phi = -\,\mathrm{E}\times$ area of the gaussian surface

The negative sign shows that the flux is *entering into* the gaussian surface.

$\therefore\ \Phi = -\,\mathrm{E}\times4\pi r^2 = -\,1{\cdot}5\times10^{-2}\times4\pi\,(0{\cdot}2)^2$ ...(*i*)

According to Gauss's theorem,

$$\Phi = \frac{q}{\varepsilon_0} \qquad ...(ii)$$

From equations (*i*) and (*ii*), we have

$$\frac{q}{\varepsilon_0} = -\,1{\cdot}5\times10^3\times4\pi\times(0{\cdot}2)^2$$

or $q = -\,1{\cdot}5\times10^3\times4\pi\,\varepsilon_0\times(0{\cdot}2)^2$

$$= \frac{-\,1{\cdot}5\times10^3\times(0{\cdot}2)^2}{9\times10^9} = \mathbf{-\,6{\cdot}67\times10^{-9}\ C}$$

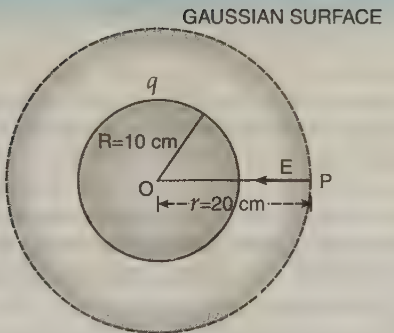

Fig. 4.02.

Chapter 5. Capacitors

roblem 5.01. A radioactive source in the form of a sphere of diameter 10^{-3} m emits β-particles at a nt rate of $6{\cdot}25\times10^{10}$ particles per second. If the source ctrically insulated, how long will it take for its ial to rise by 1·0 V, assuming that 80% of emitted β-es escape from the surface ? *(Roorkee, 1989)*

ol. Here, radius of the metal sphere,

$$r = \frac{10^{-2}}{2} = 0{\cdot}5\times10^{-3}\ \mathrm{m}$$

herefore, capacitance of the metal sphere,

$$C = 4\pi\,\varepsilon_0\,r = \frac{1}{9\times10^9}\times0{\cdot}5\times10^{-7} = \frac{1}{18}\times10^{-12}\ \mathrm{F}$$

equired electric potential of the metal sphere,

V = 1·0 V

q is the charge that should escape from the metal e (in the form of β-particles), so as to raise it to the ed potential, then

$$q = \mathrm{C\,V} = \frac{1}{18}\times10^{-12}\times1 = \frac{1}{18}\times10^{-12}\ \mathrm{C}$$

he number of β-particles emitted per second by the , $n = 6{\cdot}25\times10^{10}$ s^{-1}

ince 80% of emitted β-particles escape from the metal e, the number of β-particles escaping per second

$$= \frac{6{\cdot}25\times10^{10}\times80}{100} = 5\times10^{10}\ \mathrm{s}^{-1}$$

Since charge on a β-particle is $1{\cdot}6\times10^{-19}$ C, the amount of charge escaping per second

$= 5\times10^{10}\times1{\cdot}6\times10^{-19} = 8\times10^{-9}$ C s^{-1}

Then, required time, $t = \frac{q}{8\times10^{-9}}$

$$= \frac{\frac{8}{9}\times10^{-12}}{8\times10^{-9}} = \mathbf{6{\cdot}944\times10^{-6}\ s}$$

Problem 5.02. A capacitor of capacitance C_1 = 1·0 μF withstands the maximum voltage V_1 = 6·0 kV, while another capacitor of capacitance C_2 = 2·0 μF withstands the maximum voltage 4·0 kV. What maximum voltage will the system of these two capacitors withstand, if they are connected in series ? *(M.N.R. 1992)*

Sol. Here, $C_1 = 1{\cdot}0\ \mu F = 10^{-6}$ F ;

$C_2 = 2{\cdot}0\ \mu F = 2\times10^{-6}$ F

Maximum voltage, which capacitor C_1 can withstand,

$V_1 = 6{\cdot}0$ kV $= 6\times10^3$ V

Maximum voltage, which capacitor C_2 can withstand,

$V_2 = 4{\cdot}0$ kV $= 4\times10^3$ V

Let q_1 and q_2 be the values of maximum charge that can be stored by the capacitors C_1 and C_2 respectively.

Then, $q_1 = C_1 V_1 = 10^{-6} \times 6 \times 10^3 = 6 \times 10^{-3}$ C

and $q_2 = C_2 V_2 = 2 \times 10^{-6} \times 4 \times 10^3 = 8 \times 10^{-3}$ C

When capacitors are connected in series, charge on the plates of each capacitor is same. Therefore, when the two capacitors are connected in series, the maximum voltage should not charge C_1 or C_2 to a value more than 6×10^{-3} C, (the maximum charge which the capacitor C_1 can withstand). Therefore, when the capacitors are connected in series,

$$q_{max} = 6 \times 10^{-3}\ \text{C}$$

Let C be capacitance of the two capacitors in series. Then,

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{10^{-6}} + \frac{1}{2 \times 10^{-6}} = \frac{2+1}{2 \times 10^{-6}}$$

or $C = \frac{2}{3} \times 10^{-6}$ F

Therefore, the maximum voltage which the series combination can withstand,

$$V_{max} = \frac{q_{max}}{C} = \frac{6 \times 10^{-3}}{\frac{2}{3} \times 10^{-6}} = 9 \times 10^3\ \text{V}$$

Problem 5.03. From the given Fig. 5.01, find the value of the capacitance C, if the equivalent capacitance between points A and B is to be 1 μF. *(I.I.T. 1997)*

Sol. Refer to the arrangement of capacitors in Fig. 5.01.

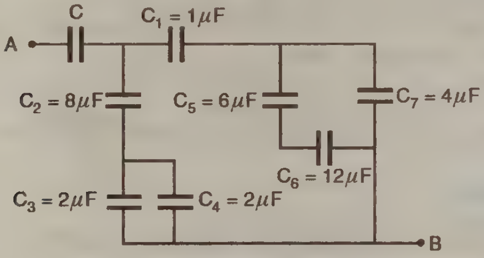

Fig. 5.01.

The two capacitors C_3 and C_4 are in parallel. Their effective capacitance,

$$C_{34} = C_3 + C_4 = 2 + 2 = 4\ \mu F$$

Also, the two capacitors C_5 and C_6 are in series so that their effective capacitance,

$$C_{56} = \frac{C_5\, C_6}{C_5 + C_5} = \frac{6 \times 12}{6 + 12} = 4\ \mu F$$

The given arrangement of capacitors is equivalent to the arrangement as shown in Fig. 5.02.

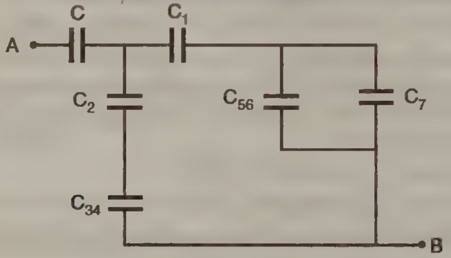

Fig. 5.02.

Since the capacitors C_2 and C_{34} are in series, their effective capacitance,

$$C_{234} = \frac{C_2 \times C_{34}}{C_2 + C_{34}} = \frac{8 \times 4}{8 + 4} = \frac{8}{3}\ \mu F$$

Also, the capacitors C_{56} and C_7 are in parallel so t their effective capacitance,

$$C_{567} = C_{56} + C_7 = 4 + 4 = 8\ \mu F$$

The arrangement shown in Fig. 5.02 is now equiva to the arrangement shown in Fig. 5.03.

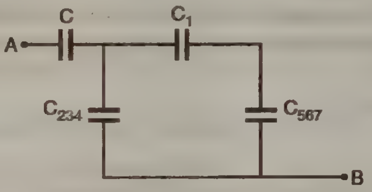

Fig. 5.03.

Since the capacitors C_1 and C_{567} are in series, t effective capacitance,

$$C' = \frac{C_1 \times C_{567}}{C_1 + C_{567}} = \frac{1 \times 8}{1 + 8} = \frac{8}{9}\ \mu F$$

The arrangement shown in Fig. 5.03 can be represen as shown in Fig. 5.04.

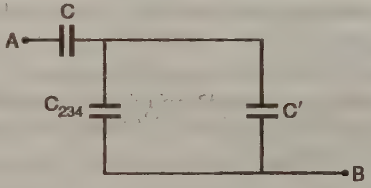

Fig. 5.04

Now, the capacitors C_{234} and C' are in parallel. T effective capacitance,

$$C'' = C_{234} + C' = \frac{8}{9} + \frac{8}{9} = \frac{32}{9}\ \mu F$$

Finally, the given arrangement of the capacitors redu to the one shown in Fig. 5.05.

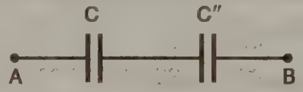

Fig. 5.05.

Since the equivalent capacitance of the gi arrangement between points A and B is 1 μF, it follows

$$\frac{1}{C} + \frac{1}{C''} = \frac{1}{1} \quad \text{or} \quad \frac{1}{C} = 1 - \frac{1}{C''} = 1 - \frac{1}{32/9} = \frac{23}{32}$$

or $C = \frac{23}{32} = 1{\cdot}39\ \mu F$

Problem 5.04. A capacitor is filled with two dielec of same dimensions but of dielectric constant $K_1 = 2$ an $= 3$ respectively. Find the ratio of the capacities in possible arrangements. *(M.N.R. 1*

Thought Process

1. One arrangement of filling the capacitor is to us two dielectric slabs each of area A and thickness d/2 that of the distance between the plates of the capaci As such, the capacitor acts as a series combinatio two capacitors [Fig. 5.06].

2. The other arrangement of filling the capacitor is to take the two dielectric slabs each of thickness d and area A/2. As such, the capacitor acts as a parallel combination of two capacitors [Fig. 5.07].

Sol. A capacitor having plates of area A and separation be filled with two dielectric slabs of dielectric constants d K_2 in the two ways as shown in the Fig. 5.06 and 5.07.

Arrangement in Fig. 5.06 : Let C_1 and C_2 be the ctances of the two parts of the capacitor having dielectric each of area A, thickness $d/2$ and of dielectric constants 2 and $K_2 = 3$.

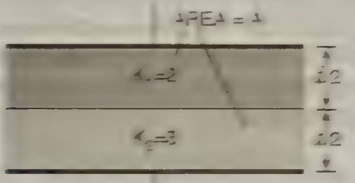

Fig. 5.06.

Then, $C_1 = \frac{\varepsilon_0 K_1 A}{d/2} = \frac{2\varepsilon_0 \times 2 \times A}{d} = \frac{4\varepsilon_0 A}{d}$

and $C_2 = \frac{\varepsilon_0 K_2 A}{d/2} = \frac{2\varepsilon_0 \times 3 \times A}{d} = \frac{6\varepsilon_0 A}{d}$

The capacitor behaves as the parallel combination of C_1 C_2. Therefore, the equivalent capacitance of the gement is given by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{d}{4\varepsilon_0 A} + \frac{d}{6\varepsilon_0 A} = \frac{15\,d}{12\,\varepsilon_0 A}$$

or $$C = \frac{12\,\varepsilon_0 A}{5\,d}$$

Arrangement in Fig. 5.07 : Let C_1' and C_2' be the citances of the two parts of the capacitor having dielectric each of area A/2, thickness d and dielectric constants 2 and $K_2 = 3$.

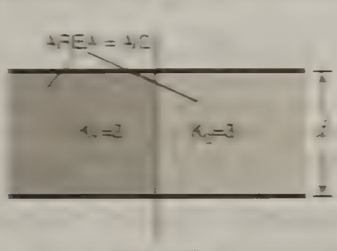

Fig. 5.07

Then, $C_1' = \frac{\varepsilon_0 K_1 . A/2}{d} = \frac{\varepsilon_0 \times 2 \times A}{2d} = \frac{\varepsilon_0 A}{d}$

and $C_2' = \frac{\varepsilon_0 K_2 . A/2}{d} = \frac{\varepsilon_0 \times 3 \times A}{2d} = \frac{3\varepsilon_0 A}{2d}$

The capacitor behaves as the parallel combination of C_1' C_2'.

Therefore, the equivalent capacitance of the arrangement en by

$$C' = C_1' + C_2 = \frac{\varepsilon_0 A}{d} + \frac{3\varepsilon_0 A}{2d} = \frac{5\varepsilon_0 A}{2d}$$

Hence $\frac{C}{C'} = \frac{12\varepsilon_0 A}{5d} \Big/ \frac{5\varepsilon_0 A}{2d} = \frac{24}{25}$

Problem 5.05. A parallel plate capacitor is maintained at a certain potential difference. When a 3 mm thick slab is introduced to keep the potential difference same, the distance between the plates has to be increased by 2·4 mm. Find the dielectric constant of the slab.

(M.N.R. 1982 ; I.S.M. Dhanbad, 1982)

Thought Process

1. It follows that only a part of the space between the two plates has been filled.

2. The charge on the capacitor does not change on introducing dielectric between the plates of a capacitor.

Sol. Let A be the area of each plate and d (in metre) be separation between the two plates of the capacitor.

The capacitance of the parallel plate capacitor, $C = \frac{\varepsilon_0 A}{d}$

When dielectric slab is introduced. The charge on the plates remains unchanged. Therefore, on introducing dielectric slab and increasing the separation between the plates, the capacitance of the capacitor should not alter, so that potential difference remains the same.

Now, the capacitance of the capacitor, when dielectric slab of thickness t is introduced, is given by

$$C' = \frac{\varepsilon_0 A}{d' - t\left(1 - \frac{1}{K}\right)}$$

where d' is the new value of the separation between the two plates of the capacitor.

Here, $d' = d + 2{\cdot}4 \text{ mm} = d + 2{\cdot}4 \times 10^{-3}$ m ;

$t = 3 \text{ mm} = 3 \times 10^{-3}$ m]

$$\therefore \quad C' = \frac{\varepsilon_0 A}{(d + 2{\cdot}4 \times 10^{-3}) - 3 \times 10^{-3}\left(1 - \frac{1}{K}\right)}$$

Equating C and C′, we have

$$\frac{\varepsilon_0 A}{(d + 2{\cdot}4 \times 10^{-3}) - 3 \times 10^{-3}\left(1 - \frac{1}{K}\right)} = \frac{\varepsilon_0 A}{d}$$

or $$(d + 2{\cdot}4 \times 10^{-3}) - 3 \times 10^{-3}\left(1 - \frac{1}{K}\right) = d$$

or $$1 - \frac{1}{K} = \frac{2{\cdot}4 \times 10^{-3}}{3 \times 10^{-3}} = 0{\cdot}8 \quad \text{or} \quad \frac{1}{K} = 0{\cdot}2$$

or $$K = 5$$

Problem 5.06. A 28 μF capacitor is charged to 100 V and another 2 μF capacitor to 200 V. Then they are connected in parallel. Determine the total initial and final energies. Account for the difference in two values.

(I.S.M. Dhanbad, 1983)

Sol. Here, $C_1 = 28\ \mu F = 28 \times 10^{-6}$ F ;

$C_2 = 2\ \mu F = 2 \times 10^{-6}$ F ;

$V_1 = 100$ V V ; $V_2 = 200$ V

Charge on capacitor C_1,

$q_1 = C_1 V_1 = 28 \times 10^{-6} \times 100 = 28 \times 10^{-4}$ C

Charge on capacitor C_2,

$q_2 = C_2 V_2 = 28 \times 10^{-6} \times 100 = 28 \times 10^{-4}$ C

When the two charged capacitors are connected in parallel, they will share charges, till a common potential is attained. If V is common potential, then

$$V = \frac{\text{total charge}}{\text{total capacitor}} = \frac{q_1 + q_2}{C_1 + C_2}$$

$$= \frac{28\times10^{-4} + 6\times10^{-4}}{28\times10^{-6} + 3\times10^{-6}} = 109\cdot68 \text{ V}$$

Total initial energy of the two capacitors,

$$U_1 = \frac{1}{2} C_1 C_1^2 + \frac{1}{2} C_2 V_2^2$$

$$\text{or } U_1 = \frac{1}{2} \times 28\times10^{-6} \times (100)^2 + \frac{12}{2} \times 3\times10^{-6} \times (200)^2$$

$$= 0\cdot14 + 0\cdot06 = 0\cdot2 \text{ J}$$

Total final energy of the two capacitors,

$$U_2 = \frac{1}{2}(C_1 + C_2) V^2$$

$$\text{or } U_2 = \frac{1}{2}(28\times10^{-6} + 3\times10^{-6}) \times (109\cdot68)^2$$

$$= 0\cdot1865 \text{ J}$$

Loss of energy, $U_1 - U_2 = 0\cdot2 \;\; 0\cdot1865 = \mathbf{0\cdot0135 \text{ J}}$

The loss of energy appears as heat and electrical spark.

Problem 5.07. The capacitance of a variable radio capacitor can be changed from 50 pF to 950 pF by turning the dial from 0° to 180°. With the dial set at 180°, the capacitor is connected to a 400 V battery. After charging, the capacitor is disconnected from the battery and the dial is turned at 0°.

(*a*) What is the potential difference across the capacitor, when the dial reads 0° ?

(*b*) How much work is required to turn the dial, if friction is neglected ? (*M.N.R. 1986*)

Thought Process

1. *When the dial is turned at 0°C (from 180°), the capacitance of the capacitor decreases from 950 pF to 50 pF.*
2. *The decrease in capacitance of the capacitor by certain factor brings about increase in potential difference across its plates by the same factor. Since electrostatic energy stored is directly proportional to square of the potential difference, increase in potential energy of the capacitor is quite large.*
3. *The work done to turn the dial at 0° is equal to the increase in the potential energy of the capacitor.*

Sol. Here, the source voltage, V = 400 V

The capacitance of the capacitor, when dial is at 0°,

$$C_1 = 50 \text{ pF} = 50 \times 10^{-12} \text{ F}$$

The capacitance of the capacitor, when dial is at 180°,

$$C_2 = 950 \text{ pF} = 950 \times 10^{-12} \text{ F}$$

The battery is connected to the capacitor, when dial is at 180° *i.e.* when its capacitance is C_2.

Therefore, charge stored in the capacitor,

$$q = C_2 V = 950 \times 10^{-12} \times 400 = 3\cdot8 \times 10^{-7} \text{ C}$$

(*a*) After charging, the dial is turned at 0°, so that its capacitance becomes C_1.

Therefore, potential difference across the capacitor, when the dial reads 0°,

$$V' = \frac{q}{C_1} = \frac{3\cdot8\times10^{-7}}{50\times10^{-12}} = \mathbf{7600 \text{ V}}$$

(*b*) Initial potential energy of the capacitor,

$$U_1 = \frac{1}{2} C_2 V^2 = \frac{1}{2} \times 950 \times 10^{-12} \times (400)^2$$

$$= 7\cdot6 \times 10^{-5} \text{ J}$$

Final potential energy of the capacitor,

$$U_2 = \frac{1}{2} C_1 V'^2 = \frac{1}{2} \times 50 \times 10^{-12} \times (7600)^2$$

$$= 1\cdot444 \times 10^{-3} \text{ J}$$

Therefore, work done to turn the dial,

$$W = U_2 - U_1 = 1\cdot444 \times 10^{-3} - 7\cdot6 \times 10^{-5}$$

$$= \mathbf{1\cdot368 \times 10^{-3} \text{ J}}$$

Problem 5.08. A conductor of capacity 15 uni charged to potential of 40 units and is then made to s its charge with an uncharged sphere, whereby the com potential drops to 30 units. Find the radius of the sphe terms of the loss of energy due to sharing of charge.

(*I.S.M. Dhanbad, 1*

Sol. Here, capacitance of conductor,

$$C_1 = 15 \text{ F (SI units)}$$

Potential of the conductor, V = 40 V (SI u

Therefore, charge on the conductor,

$$q_1 = C_1 V = 15 \times 40 = 600 \text{ C}$$

Let *r* (metre) be the radius of the uncharged spl

Then,

$$\text{Capacitance of the sphere, } C_2 = 4\pi\varepsilon_0 r = \frac{r}{9\times10}$$

Since the sphere is uncharged ($q_2 = 0$), the com potential,

$$V' = \frac{q_1 + q_2}{C_1 + C_2} = \frac{600 + 0}{15 + \frac{r}{9\times10^9}} = \frac{600}{15 + \frac{r}{9\times10^9}}$$

Initial potential energy of the system,

$$U_1 = \frac{1}{2} C_1 V^2 + \frac{1}{2} C_2 \times 0^2 = \frac{1}{2} \times 15 \times 40^2 = 1\cdot2 \times 10$$

Final potential energy of the system,

$$U_2 = \frac{1}{2}(C_1 + C_2) V'^2$$

$$= \frac{1}{2}\left(15 + \frac{r}{9\times10^9}\right) \times \left(\frac{600}{15 + \frac{r}{9\times10^9}}\right)^2 = \frac{1\cdot8\times}{15 + \frac{}{9\times}}$$

$$= \frac{1\cdot62\times10^{15}}{1\cdot35\times10^{11} + r}$$

On sharing charges , there is always loss of en Therefore,

$$\text{loss of energy, } \Delta U = 1\cdot2\times10^4 - \frac{1\cdot62\times10^{15}}{1\cdot35\times10^{11} + r}$$

$$\text{or} \quad \frac{1\cdot62\times10^{15}}{1\cdot35\times10^{11} + r} = 1\cdot2\times10^4 - \Delta U$$

$$\text{or} \quad 1\cdot35\times10^{11} + r = \frac{1\cdot62\times10^{15}}{1\cdot2\times10^4 - \Delta U}$$

$$\text{or} \quad r = \frac{1\cdot62\times10^{15}}{1\cdot2\times10^4 - \Delta U} - 1\cdot35\times10^{11}$$

$$= \frac{1{\cdot}62\times10^{15} - 1{\cdot}35\times1{\cdot}2\times10^{15} + 1{\cdot}35\times10^{11}\,\Delta U}{1{\cdot}2\times10^{4} - \Delta U}$$

$$= \frac{1{\cdot}62\times10^{15} - 1{\cdot}62\times10^{15} + 1{\cdot}35\times10^{11}\,\Delta U}{1{\cdot}2\times10^{4} - \Delta U}$$

$$= \frac{\mathbf{1{\cdot}35\times10^{11}\,\Delta U}}{\mathbf{1{\cdot}2\times10^{4} - \Delta U}}$$

Problem 5.09. Fig 5.08 shows two identical parallel e capacitors connected to a battery with the switch S ed. The switch is now opened and the free space veen the plates of the capacitors is filled with a ectric of dielectric constant (or relative permittivity) 3. the ratio of the total electrostatic energy stored in both citors before and after the introduction of the dielectric.

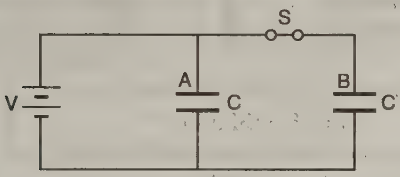

Fig. 5.08.

ought Process

1. *On introduction of dielectric slab, the potential difference between the plates of a capacitor decreases by a factor equal to K (dielectric constant).*
2. *When the switch S is opened, the potential difference will not decrease in case of capacitor A. It is because, even on opening the switch, the capacitor A remains connected to the battery.*

Sol. ***When the switch is closed.*** The potential difference ss the plates of both the capacitors will be equal to the ery voltage V.

Therefore, electrostatic energy stored in the two citors, $U_1 = \frac{1}{2} C V^2 \times 2 = C V^2$

When the switch is opened and dielectric is introduced. en dielectric of dielectric constant K = 3 is introduced een the plates of the two capacitors, the capacitance of of the two capacitors A and B will become K times *i.e.* will become equal to 3 C. Further, whereas the potential erence across the capacitor A will remain V (as it still ains connected to the battery), the potential difference ss the capacitor B will become $\frac{V}{3}$.

Therefore, electrostatic energy stored in the two citors,

$$U_2 = \frac{1}{2}(3\,C)\times V^2 + \frac{1}{2}(3\,C)\times\left(\frac{V}{3}\right)^2$$

$$= \frac{3}{2} C V^2 + \frac{1}{6} C V^2 = \frac{5}{3} C V^2$$

Thus, $\frac{U_1}{U_2} = \frac{C V^2}{\frac{5}{3} C V^2} = \frac{3}{5}$

Problem 5.10. Two parallel plate capacitors A and B e the same separation d = 8·85 × 10^{-4} m between the es. The plate areas of A and B are 0·04 m^2 and 0·02 m^2 respectively. A slab of dielectric constant (relative permittivity) K = 9, has dimensions, such that it can exactly fill the space between the plates of capacitor B.

(*i*) The dielectric slab is placed inside A as shown in Fig. 5.09. A is then charged to a potential difference of 110 V. Calculate the capacitance of A and the energy stored in it.

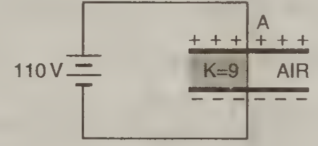

Fig. 5.09

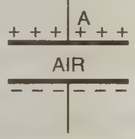

Fig. 5.10

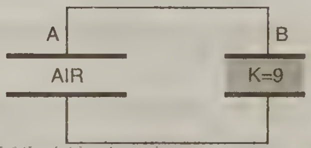

Fig. 5.11

(*ii*) The battery is disconnected and then the dielectric slab is removed from A [Fig. 5.10]. Find the work done by the external agency in removing the slab from A.

(*iii*) The same dielectric slab is now placed inside B, filling it completely. The two capacitors A and B are then connected as shown in Fig. 5.11. Calculate the energy stored in the system. (*I.I.T. 1993*)

Thought Process

1. *When the space between the plates of a capacitor is partially filled with a dielectric slab (thickness of slab is equal to separation between the plates), the two parts of the capacitor behave as two separate capacitors and the arrangement may be looked as the parallel combination of the two parts behaving as two separate capacitors.*
2. *When dielectric slab is removed from the space between the plates of a charged capacitor, the capacitance decreases, while the potential difference increases by the factor equal to K (dielectric constant).*

Since $U = \frac{1}{2} C V^2$, *the potential energy increases by a factor* $\frac{1}{K} \times K^2$ *i.e. K. The energy of the capacitor increases at the expense of the work done in removing the dielectric slab.*

Sol. Here, Area of the plates of capacitor A,

$$A_1 = 0{\cdot}04 \text{ m}^2$$

Area of the plates of capacitor B,

$$A_2 = 0{\cdot}02 \text{ m}^2$$

Separation between the plates of the two capacitors,

$$d_1 = d_2 = 8{\cdot}85 \times 10^{-4} \text{ m}$$

Since the dielectric slab can exactly fill the space between the plates of capacitor B,

area of dielectric slab, $A_2 = 0{\cdot}02 \text{ m}^2$;

and dielectric constant of the dielectric slab, K = 9

(*i*) As shown in Fig. 5.09, when the dielectric slab is introduced between the plates of capacitor A, then half of the space between the two plates gets filled with slab and the other half has air. Let C′ and C″ be the capacitances of the two parts of the capacitor A. The area of the plates of capacitor C′ is A_2, same as that of dielectric ; while that of C″ is equal to $A_1 - A_2$. As already said, the capacitor A can be looked as a parallel combination of C′ and C″ and its capacitance is given by

$$C_1 = C' + C'' = \frac{\varepsilon_0 K A_2}{d} + \frac{\varepsilon_0 (A_1 - A_2)}{d}$$

Since $A_1 = 2 A_2$, it follows that

$$C_1 = \frac{\varepsilon_0 K A_2}{d} + \frac{\varepsilon_0 A_2}{d} = \frac{\varepsilon_0 A_2}{d}(K+1)$$

$$= \frac{8 \cdot 85 \times 10^{-12} \times 0 \cdot 02 (9+1)}{8 \cdot 85 \times 10^{-4}} = \mathbf{2 \times 10^{-9}\ F}$$

The energy stored in the capacitor A on applying a potential difference of 110 V,

$$U_1 = \frac{1}{2} C_1 V^2 = \frac{1}{2} \times 2 \times 10^{-9} \times (110)^2 = \mathbf{1{\cdot}21 \times 10^{-5}\ J}$$

(ii) As shown in Fig. 5.10, when the battery is disconnected and the dielectric slab is removed, the capacitor A becomes completely an air capacitor and its capacitance becomes

$$C_1{}' = \frac{\varepsilon_0 A_1}{d} = \frac{8 \cdot 85 \times 10^{-2} \times 0 \cdot 04}{8 \cdot 85 \times 10^{-4}} = 4 \times 10^{-10}\ F$$

Let V′ be the value of potential difference across the capacitor A on removing the dielectric slab. Since the charge on the capacitor remains same, we have

$$C_1{}' V' = C_1 V$$

or $$V' = \frac{C_1 V}{C_1{}'} = \frac{2 \times 10^{-9} \times 110}{4 \times 10^{-10}} = 550\ V$$

Therefore, electrostatic energy stored in the capacitor on removing the dielectric slab [Fig. 5.08 (*c*)],

$$U_2 = \frac{1}{2} C_1{}' V'^2 = \frac{1}{2} \times 40 \times 10^{-10} \times (550)^2$$

$$= 6{\cdot}05 \times 10^{-5}\ J$$

The energy of the capacitor increases at the expense of the work done by the external agency in removing the slab. Therefore, work done by the external agency

$$W = U_2 - U_1 = 6{\cdot}05 \times 10^{-5} - 1{\cdot}21 \times 10^{-5}$$

$$= \mathbf{4{\cdot}84 \times 10^{-5}\ J}$$

(iii) Refer to Fig. 5.11 : The capacitance of the capacitor B, when dielectric slab is placed between its plates,

$$C_2 = \frac{4 \varepsilon_0 K A_2}{d} = \frac{8 \cdot 85 \times 10^{-12} \times 9 \times 0 \cdot 02}{8 \cdot 85 \times 10^{-4}}$$

$$= 1{\cdot}8 \times 10^{-9}\ F$$

When the charged capacitor A (without slab) is connected to the capacitor B, the capacitance of the parallel combination becomes

$$C = C_1{}' + C_2 = 4 \times 10^{-10} + 1{\cdot}8 \times 10^{-9}$$

$$= 2{\cdot}2 \times 10^{-9}\ F$$

Charge on the parallel combination of the capacitors,

$$q = C_1{}' V' = 4 \times 10^{-10} \times 550\ C$$

Therefore, energy stored in the combination,

$$U = \frac{1}{2}\frac{q^2}{C} = \frac{(4 \times 10^{-10} \times 550)^2}{2 \times 2 \cdot 2 \times 10^{-9}} = \mathbf{1{\cdot}1 \times 10^{-5}\ J}$$

Problem 5.11. Two square metallic plates of 1 m side kept 0·01 m apart like a parallel plate capacitor in air in s a way that one of their edges is perpendicular to an surface in a tank filled with an insulating oil. The plates connected to a battery of e.m.f. 500 V. The plates are t lowered vertically into the oil at a speed of 0·001 m Calculate the current drawn from the battery during process. Dielectric constant of oil = 11, ε_0 = 8·85 $C^2 N^{-1}$

(I.I.T. 1

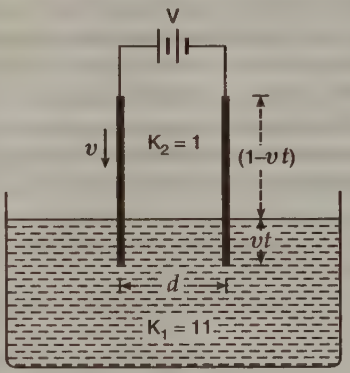

Fig. 5.12

Thought Process

1. *As the plates of the capacitor are lowered into th the capacitance of the capacitor goes on increasing to continuous increase in the area of the diele (insulating oil) between the two plates.*
2. *Since battery remains connected to the capac potential difference across the plates remains equ the battery voltage.*
3. *As capacitance is continuously increasing electrostatic energy also goes on increasing. For capacitor draws current from the battery.*

Sol. Suppose that at $t = 0$, the edges of the two squ plates of the parallel plate capacitor just touch the oil surf If the plates are lowered with velocity v, then at any tin length $v\,t$ of the vertical side of the plates will be inside oil [Fig. 5.12]. Since the plates are square of side 1 m, the le $(1 - v\,t)$ of the vertical side will be in air.

Thus, the capacitor is partially filled with oil partially with air. Let C_1 and C_2 be capacitances of the parts of the capacitor having oil and air respectively as t dielectrics. If A_1 is area of the portion of the plates havin inbetween, then

$$C_1 = \frac{\varepsilon_0 K_1 A_1}{d}$$

Here, $A_1 = v\,t \times 1\,1 = 11$

$$\therefore \quad C_1 = \frac{\varepsilon_0 \times 11 \times v\,t}{d} = \frac{11\,\varepsilon_0\,v\,t}{d}$$

On the other hand, if A_2 is area of the portion of plates having air inbetween, then

$$C_2 = \frac{\varepsilon_0 \times K_2 A_2}{d}$$

Here, $A_2 = (1 - v\,t) \times 1 = (1 - v\,t)\ m^2$

and $K_2 = 1$

$$\therefore \quad C_2 = \frac{\varepsilon_0 \times 1 \times (1 - v)}{d} = \frac{\varepsilon_0 (1 - v\,t)}{d}$$

The given capacitor is equivalent to a parallel bination of C_1 and C_2. If C is capacitance of the given citor at any time t, then

$$C = C_1 + C_2 = \frac{11\,\varepsilon_0\, v\,t}{d} + \frac{\varepsilon_0\,(1 - v\,t)}{d}$$

$$= \frac{\varepsilon_0\,(1 - 10\,v\,t)}{d}$$

Since the capacitor remains connected to the battery, the ntial difference across the capacitor always remains equal e battery voltage V.

Therefore, electrostatic energy stored in the capacitor y time t,

$$U = \frac{1}{2} C V^2 = \frac{1}{2} \frac{\varepsilon_0\,(1 + 10\,v\,t)}{d} V^2 \qquad ...(i)$$

If q is charge on the capacitor (supplied by battery) at any t, then

$$U = \frac{1}{2} q V \qquad ...(ii)$$

From the equations (*i*) and (*ii*), we have

$$\frac{1}{2} q V = \frac{1}{2} \frac{\varepsilon_0\,(1 + 10\,v\,t)}{d} V^2$$

$$\text{or} \qquad q = \frac{\varepsilon_0\,(1 + 10\,v\,t)}{d} V$$

Differentiating both sides *w.r.t.* t, we have

$$\frac{dq}{dt} = \frac{d}{dt}\left(\frac{\varepsilon_0\,(1 + 10\,v\,t)\,V}{d}\right)$$

$$= \frac{\varepsilon_0}{d}(0 + 10\,v)\,V = \frac{10\,\varepsilon_0\,v\,V}{d}$$

Now, $\frac{dq}{dt} = I$, the current drawn by the capacitor from the battery.

$$\therefore \qquad I = \frac{10\,\varepsilon_0\,v\,V}{d}$$

Here, $\varepsilon_0 = 8{\cdot}85 \times 10^{-12}\ C^2\,N^{-1}\,m^{-2}$;
$d = 0{\cdot}01$ m ; $v = 0{\cdot}001\ m\,s^{-1}$; V = 500 volt

$$\therefore\ I = \frac{10 \times 8{\cdot}85 \times 10^{-12} \times 0{\cdot}001 \times 500}{0{\cdot}01}$$

$$= \mathbf{4{\cdot}425 \times 10^{-9}\ A}$$

MULTIPLE CHOICE QUESTIONS FROM COMPETITIVE EXAMINATIONS

Chapter 1. Coulomb's Law

PART I. TEXT-BASED QUESTIONS

1. Static electricity is produced due to

(A) friction (B) conduction
(C) induction (D) both A and C. (*C.E.T. 1999*)

2. A polythene piece rubbed with wool is found to have a negative charge of 1·6 × 10^{-6} C. (The charge on electron is 1·6 × 10^{-19} C). Then, the number of electrons transferred is

(A) 10^{13} from wool to polythene.
(B) 10^{13} from polythene to wool.
(C) 2·56 × 10^{15} from wool to polythene.
(D) 10^{-13} from wool to polythene.

(*Karnataka Entrance, 1991*)

3. A positively charged glass rod is brought near an uncharged pith ball pendulum. The pith ball is

(A) attracted towards the rod.
(B) repelled away from the rod.
(C) not affected by the rod.
(D) attracted towards the rod, touches it and is then thrown away from it.

4. In SI, unit of permittivity is :

(A) N m^2 C^{-2} (B) N m^{-2} C^{-1}
(C) C^2 N^{-1} m^{-2} (D) A m^{-1}

5. Two point charges of +3 μC and − 8 μC attract each other with a force of 1 N. A charge of + 5 μC is added to each of them. Now, the force will be :

(A) 1 N (attractive) (B) 1 N (repulstive)
(C) zero (D) cannot be found.

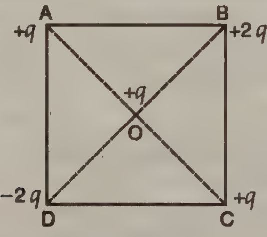
6. When air is replaced by a dielectric medium of dielectric constant K, the maximum force of attraction between two charges separated by a distance :

(A) decreases K times
(B) remains unchanged
(C) increases K times
(D) decreases K^2 times (*C.B.S.E. 1999*)

7. Force between two stationary charges, when placed in free space is 10 N. If they are placed in a medium of relative permittivity 5, the force between them is

(A) 50 N (B) 2 N
(C) 0·5 N (D) 10 N (*C.E.T. 1999*)

8. Four charges are arranged at the corners of a square ABCD as shown in figure. The force on the charge +*q* kept at the centre O is



(A) along the diagonal AC.
(B) along the diagonal BD.
(C) perpendicular to side AB.
(D) zero. (*N.C.E.R.T. 1983*)

9. Three charges +4 *q*, Q and *q* are placed in a straight line of length *l* at points at distances 0, *l* / 2 and *l* respectively. What should be Q in order to make the net force on *q* to zero ?

(A) − *q* (B) − 2 *q*
(C) − *q*/2 (D) 4 *q* (*A.I.I.M.S. 19*

10. A charge q_1 exerts some force on a second charge q_2. A thi charge q_3 is brought near. Then, force exerted by q_1 on will

(A) decrease in magnitude.
(B) increase in magnitude.
(C) remain unchanged.
(D) increase, if q_2 is of the same sign as q_1 and will decrea if q_2 is of opposite sign. (*N.C.E.R.T. 19*

PART II. THOUGHT-BASED QUESTIONS

11. Choose the correct answer :

(A) Total charge present in the universe is constant.
(B) Total positive charge present in the universe is consta
(C) Total negative charge present in the universe is consta
(D) Total number of charged particles present in t universe is constant.

12. Five balls numbered 1 to 5 are suspended using separ threads. Pairs (1, 2), (2, 4) and (4, 1) show electrosta attraction, while pairs (2, 3) and (4, 5) show repulsi Therefore, ball 1 must be

(A) positively charged. (B) negatively charged.
(C) neutral. (D) made of metal.
(*N.C.E.R.T. 19*

13. Two small spheres each having the charge *q* are suspend by insulating threads of length *l* from a hook . Th arrangement is taken in space, where there is gravitational effect. Then, the angle between the t suspensions and the tension in each will be

(A) 180° ; $\frac{1}{4\pi\varepsilon_0}\frac{q^2}{(2l)^2}$ (B) 90° ; $\frac{1}{4\pi\varepsilon_0}\frac{q^2}{l^2}$
(C) 180° ; $\frac{1}{4\pi\varepsilon_0}\frac{q^2}{2l^2}$ (D) 180° ; $\frac{1}{4\pi\varepsilon_0}\frac{q^2}{l^2}$ (*I.I.T. 19*

14. A soap bubble is given a negative charge. Then, its radi

(A) decreases
(B) increases
(C) remains unchanged
(D) nothing can be predicted. (*M.N.R. 19*

15. A charge *q* is divided into two parts *i.e.* *q*' and *q* − *q*'. If t two parts exert a maximum force of repulsion on each oth then the ratio $\frac{q'}{q}$ is given by

(A) 1 : 2 (B) 2 : 1
(C) 1 : 4 (D) 4 : 1

16. A charge *q* is placed at the centre of the line joining t equal positive charges Q. The system of the three charg will be in equilibrium, if *q* is equal to

(A) − Q/2 (B) − Q/4
(C) + Q/4 (D) + Q/2
(*C.B.S.E. 1995 ; I.I.T. 19*

17. Two charges each of +*q* units are placed along a line. A th charge of − *q* / 4 is placed midway between them. T system will

(A) be in equilibrium (B) not be in equilibrium
(C) lose charge (D) oscillate

18. Two equal and similar charges are placed along a straig line. A third equal and similar charge is placed midw between the two charges. Then, system will

(A) be in equilibrium (B) not be in equilibrium
(C) lose charge (D) oscillate

Two equal and similar charges are placed along a straight line. A third charge equal but opposite to the other two charges is placed midway between them. The system will :
(A) be in equilibrium (B) not be in equilibrium
(C) lose charge (D) oscillate

Point charges $+4\,q, -q$ and $+4\,q$ are kept on the X-axis at points $x = 0, x = a$ and $x = 2\,a$ respectively.
(A) Only $-q$ is in stable equilibrium.
(B) None of the charges is in equilibrium.
(C) All the charges are in unstable equilibrium.
(D) All the charges are in stable equilibrium.

(C.B.S.E. 1992)

21. Two equal negative charges $-q$ are fixed at the points $(0, a)$ and $(0, -a)$ on the Y-axis. A positive charge Q is released from rest at the point $(2\,a, 0)$ on the X-axis. The charge Q will
(A) execute simple harmonic motion above the origin.
(B) move to the origin and remain at rest.
(C) move to infinity.
(D) execute oscillatory but not simple hamonic motion.

(I.I.T. 1983)

Chapter 2. Electric Field

RT I. TEXT-BASED QUESTIONS

In SI, unit of electric field is
(A) A m^{-1} (B) N C^{-1}
(C) C m^{-1} (D) C m^{-2}

The strength of the electric field is such that an electron of charge e placed inside it experiences an electric force equal to its own weight mg. The strength of the field is given by
(A) e/mg (B) mg/e
(C) $mg\,e$ (D) cannot be found.

A cube of side b has a charge q at each of its vertices. The electric field due to this charge distribution at the centre of the cube will be
(A) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{b^2}$ (B) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{2b^2}$
(C) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{32\,q}{b^2}$ (D) zero

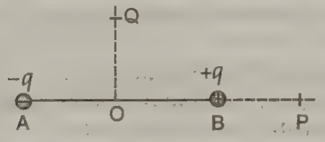
(Karnataka Entrance, 1994)

Three charges each of $+q$ are placed at the three vertices of an equilateral triangle. If the distance of centroid from each vertex of the triangle is r, then strength of electric field at the centroid will be
(A) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{3q}{r}$ (B) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{3q}{r^2}$
(C) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{r^2}$ (D) zero *(C.P.M.T. 1985)*

A given charge situated at a certain distance from an electric dipole of very small length along its axial line experiences a force F. If the distance of the charge is doubled, the force on charge will become :
(A) 2 F (B) F/2
(C) F/4 (D) F/8 *(M.N.R. 1998)*

The number of electrons to be put on a spherical conductor of radius 0·1 m to produce electric field of $0{\cdot}36\text{ N C}^{-1}$ just above the surface is
(A) $2{\cdot}7 \times 10^6$ (B) $2{\cdot}6 \times 10^6$
(C) $2{\cdot}5 \times 10^6$ (D) $2{\cdot}4 \times 10^6$ *(A.F.M.C. 1994)*

Due to the dipole shown in the figure, the electric intensity will be parallel to the dipole at the point



(A) Q (B) P
(C) Both P and Q (D) neither P, nor Q

(Roorkee, 1976)

A point Q lies on the perpendicular bisector of an electric dipole of dipole moment p. If the distance of Q from the dipole is r (much larger than the size of the dipole), then the electric field at Q is proportional to
(A) p^{-1} and r^{-2} (B) p and r^{-2}
(C) p^2 and r^{-3} (D) p and r^{-3} *(C.B.S.E. 1998)*

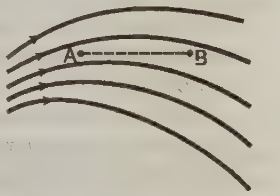
9. An electric dipole of moment p is placed in the position of stable equilibrium in a uniform electric field of intensity E. The torque required to rotate, when the dipole makes an angle θ with the initial position is
(A) $p\,E\cos\theta$ (B) $p\,E\sin\theta$
(C) $p\tan\theta$ (D) $p\cos\theta$ *(C.E.T. 1999)*

10. Torque acting on electric dipole of dipole moment $\vec{p}$ placed in uniform electric field $\vec{E}$ is
(A) $\vec{p}\times\vec{E}$ (B) $\vec{p}\,.\,\vec{E}$
(C) $\vec{p}\times(\vec{E}\times\vec{p})$ (D) $\vec{E}\,.\,\vec{p}\,/\,p^2$ *(C.B.S.E. 2001)*

11. When an electric dipole is placed in a uniform electric field, it experiences
(A) force only. (B) torque only.
(C) both force and torque.
(D) neither a force, nor a torque.

12. A dipole of electric dipole moment $\vec{p}$ is placed in a uniform electric field of strength $\vec{E}$. If θ is angle between $\vec{p}$ and $\vec{E}$, then potential energy of the dipole becomes largest, when θ is
(A) zero (B) $\pi/4$
(C) $\pi/2$ (D) π *(C.E.T. 1998)*

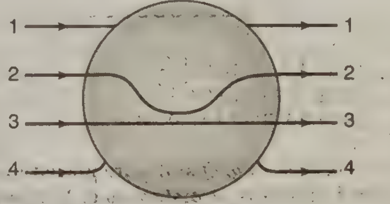
13. The figure shows electric lines of force emerging from a charged body. If the electric fields at points A and B are E_A and E_B respectively and the distance between points A and B is r, then



(A) $E_A > E_B$
(B) $E_A < E_B$
(C) $E_A = E_B$
(D) cannot be predicted.

(C.P.M.T. 1980)

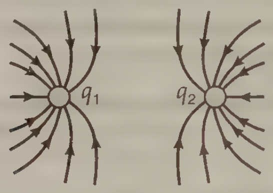
14. A metallic solid sphere is placed in a uniform electric field. The lines of force follow the path (s) shown in figure as :



(A) 1 (B) 2

(C) 3 (D) 4 (*I.I.T. 1996*)

15. Figure gives electric lines of force due to two charges q_1 and q_2. What are the signs of the two charges ?



(A) Both are negative.

(B) Both are positive.

(C) q_1 is positive but q_2 is negative.

(D) q_1 is negative but q_2 is positive. (*C.B.S.E. 1994*)

PART II. THOUGHT-BASED QUESTIONS

16. A positively charged ball hangs from a silk thread. We put a positive test charge q_0 at a point and measure $\frac{F}{q_0}$. Then, it can be predicted that the electric field strength E

(A) $> \frac{F}{q_0}$ (B) $= \frac{F}{q_0}$

(C) $< \frac{F}{q_0}$ (D) cannot be predicted.

(*C.P.M.T. 1989*)

17. A stationary charge produces :

(A) an electric field only.

(B) a magnetic field only.

(C) both electric and magnetic fields.

(D) an electromagnetic wave.

18. A proton and an electron are placed in a uniform electric field. Then,

(A) the electric forces acting on them will be equal.

(B) the magnitudes of the forces acting on them will be equal.

(C) their accelerations will be equal.

(D) the magnitudes of their accelerations will be equal.

19. A small metal ball is suspended in a uniform electric field with the help of an insulated thread. If high energy X-ray beam falls on it,

(A) the ball will be deflected in the direction of field.

(B) the ball will be deflected opposite to the direction of field.

(C) the ball will not deflect at all.

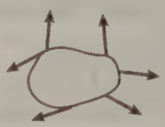
(D) the ball will fly to infinity. (*I.I.T. 1983*)

20. A charged wire is bent in the form of a semicircular arc of radius a. If charge per unit length is λ C m^{-1}, the electric field at the centre O is :

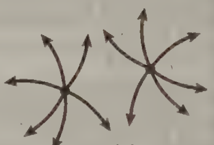
(A) $\frac{\lambda}{2\pi\varepsilon_0 a^2}$ (B) $\frac{\lambda}{4\pi^2\varepsilon_0 a}$

(C) $\frac{\lambda}{2\pi\varepsilon_0 a}$ (D) zero. (*C.B.S.E. 2000*)

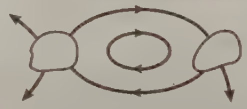
21. Which of the following figures cannot possibly represent electrostatic field lines ?



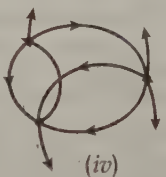
(*i*)



(*ii*)



(*iii*)



(*iv*)

(A) (*i*), (*ii*), (*iii*), (*iv*) (B) (*i*), (*ii*), (*iii*) only

(C) (*i*), (*iii*), (*iv*) only (D) (*ii*), (*iii*), (*iv*) only

(*Karnataka Entrance, 1991*)

Chapter 3. Electric Potential

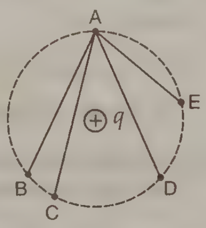
PART I. TEXT-BASED QUESTIONS

1. The work done in carrying a charge Q once round the circle of radius r with charge Q at the centre of the circle is

(A) $\frac{1}{4\pi\varepsilon_0} \cdot \frac{Q}{r}$ (B) $\frac{Q.Q}{4\pi\varepsilon_0 r}$

(C) zero (D) $\frac{Q.Q}{2r}$ (*A.I.I.M.S. 1982*)

2. In the electric field of a point charge q, a certain charge is carried from point A to B, C, D and E. Then, the work done



(A) is least along the path AB.

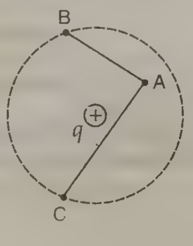
(B) is least along the path AD.

(C) is zero along any one of the paths AB, AC, AD and AE.

(D) is least along AE.

(*N.C.E.R.T. 1987*)

3. In the electric field of a point charge q shown, a charge is carried from A to B and from A to C. Compare the work done.



(A) Work done is greater along the path AC than along AB.

(B) Work done is the same in both the cases.

(C) Work done is greater along the path AB than along AC.

(D) Work done is zero in both the cases. (*N.C.E.R.T. 1986*)

4. Two small spheres each carrying a charge q placed r metres apart repel each other with a force F. If one of the spheres is taken around the other one in a circular path of radius r, the work done will be

(A) F × r (B) $F \times 2\pi r$

(C) $\frac{F}{2\pi r}$ (D) zero

(*C.P.M.T. 1991, 1975 ; N.C.E.R.T. 1983*)

5. The electric potential at the surface of an atomic nucleus (Z = 50) of radius $9{\cdot}0 \times 10^{-15}$ m is

(A) 80 V (B) 8×10^6 V

(C) 9 V (D) 9×10^5 V (*C.P.M.T. 1990*)

6. If a charge is moved against the Coulomb force of an electric field,

(A) work is done by the electric field.

(B) energy is used from some outside source.

(C) the strength of field is decreased.

(D) the energy of the system is decreased.

(*N.C.E.R.T. 1978*)

7. A helium ion and a hydrogen ion are accelerated from rest through a potential difference V to velocities v_1 and v_2 respectively. If the helium has lost one electron, the ratio v_1/v_2 is

(A) 1 (B) $\frac{1}{2}$

(B) $\frac{1}{4}$ (D) $\sqrt{2}$

8. A particle A has charge $+q$ and particle B has charge $+4q$ with each of them having the same mass m. When allowed to fall from rest through the same electrical potential difference, the ratio of their speeds v_A/v_B will become
(A) 2 : 1 (B) 1 : 2
(C) 1 : 4 (D) 4 : 1 *(M.N.R. 1991)*

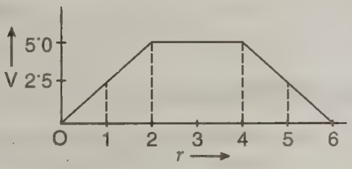
9. A ball of mass 1 g carrying a charge 10^{-8} C moves from a point A at potential 600 V to a point B at zero potential. The change in its K.E. is
(A) -6×10^{6} erg (B) -6×10^{-6} J
(C) 6×10^{-6} J (D) 6×10^{-6} erg *(Roorkee, 1988)*

10. A hollow metallic sphere of radius 10 cm is charged, such that potential of its surface is 70 V. The potential at the centre of the sphere would be
(A) 0 V (B) 7 V
(C) 70 V (D) 700 V
(A.F.M.C. 1995 ; similar I.I.T. 1993 ; M.N.R. 1990)

11. In SI, unit of electric field is :
(A) C m^{-2} (B) A m^{-1}
(C) V m^{-1} (D) C m^{-1}

12. A charge of 5 μC experiences a force of 2 N in an electric field. The potential gradient at that point is
(A) 0·4 N C^{-1} (B) 4×10^{5} N C^{-1}
(C) $2{\cdot}5 \times 10^{-6}$ N C^{-1} (D) cannot be found.

13. The variation of potential (in volt) with distance (in metre) from a fixed point is as shown in the figure. The electric field at $r = 5$ m is equal to
(A) 2·5 V m^{-1}
(B) – 2·5 V m^{-1}
(C) 0·6 V m^{-1}
(D) – 0·6 V m^{-1}



(N.C.E.R.T. 1973)

14. Let V be the electric potential at a given point. Then, the electric field E_x along X-direction at that point is given by
(A) $\int_0^\infty V\,dx$ (B) $\frac{dV}{dx}$
(C) $-\frac{dV}{dx}$ (D) $-V\frac{dV}{dx}$
(Karnataka Entrance, 1986)

15. If the electric field in a given region is zero, the potential in that region
(A) can only be zero throughout the region.
(B) can only be uniform throughout the region.
(C) can be zero or uniform throughout the region.
(D) cannot be uniform throughout the region.

16. In the direction of electric field, the electric potential
(A) decreases. (B) increases.
(C) remains unchanged. (D) becomes zero.

17. There is an electric field E in X-direction. If the work done in moving a charge of 0·2 C through a distance of 2 m along a line making an angle 60° with X-axis is 4 J, then what is the value of E ?
(A) $\sqrt{3}$ N C^{-1} (B) 4 N C^{-1}
(C) 5 N C^{-1} (D) 20 N C^{-1}
(C.E.T. 1999 ; C.B.S.E. 1995)

18. In bringing an electron towards another electron, the electrostatic potential energy of the system :
(A) increases. (B) decreases.
(C) remains unchanged. (D) becomes zero.
(C.B.S.E. 1999)

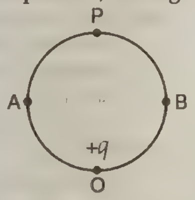
19. Identical charges ($-q$) and placed at each corner of a cube of side b. Then the electrostatic potential energy of charge ($+q$) placed at the centre of the cube will be
(A) $-\frac{4\sqrt{2}\,q^2}{\pi\,\varepsilon_0}$ (B) $\frac{8\sqrt{2}\,q^2}{\pi\,\varepsilon_0\,b}$
(C) $-\frac{4q^2}{\sqrt{3}\,\pi\,\varepsilon_0\,b}$ (D) $\frac{8\sqrt{2}\,q^2}{4\pi\,\varepsilon_0\,b}$ *(C.B.S.E. 2002)*

PART II. THOUGHT-BASED QUESTIONS

20. Can a body have charge and still be at zero potential ?
(A) Yes, always. (B) Yes, but not always.
(C) Never
(D) Depends upon the nature of the charge.

21. Can a body have electric potential and still be uncharged ?
(A) Yes, always. (B) Yes, but not always.
(C) Never
(D) Depends upon the type of the potential.

22. In the electric field of a point charge $+q$ at point O, a charge is carried from point A to B along the diameter and then along the curved path APB. Then work done
(A) along path APB is more.
(B) along path AB is more.
(C) along two paths is equal.
(D) is zero in both cases.



23. Some charge is being given to a conductor. Then its potential is
(A) maximum at surface
(B) maximum at centre
(C) same throughout the condutor
(D) maximum some where between the surface and centre.
(C.B.S.E. 2002)

24. A solid conducting sphere having a charge Q is surrounded by an uncharged concentric conducting hollow spherical shell. Let the potential difference between the surfaces of the solid sphere and that of the outer surface of the hollow shell be V. If the shell is now given a charge – 3 Q, the new potential difference between the same two surfaces is
(A) V (B) 2 V
(C) 4 V (D) – 2 V *(I.I.T. 1989)*

25. The electric potential V at any point x, y, z (all the coordinates are in metres) in space is given by $V = 4x^2$ volt. The electric field at the point (1 m, 0, 2 m) in volt metre^{-1} is
(A) 8 along negative X-axis.
(B) 8 along positive X-axis.
(C) 16 along negative X-axis.
(D) 16 along positive X-axis. *(I.I.T. 1989)*

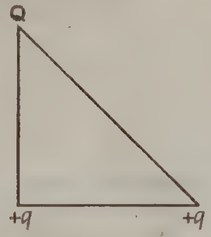
26. A uniform electric field pointing in positive X-direction exists in a region. Let A be the origin, B be the point on the X-axis at $x = +1$ cm. Then the potentials at points A, B and C satisfy :
(A) $V_A < V_B$ (B) $V_A > V_B$
(C) $V_A < V_C$ (D) $V_A > V_C$ *(I.I.T. 2001)*

27. Two equal point charges are fixed at $x = -a$ and $x = +a$ on the X-axis. Another point charge Q is placed at the origin. The change in the electrical potential energy of Q, when it is displaced by a small distance x along the X-axis, is approximately proportional to
(A) x (B) x^2
(C) x^3 (D) $1/x$ *(I.I.T. 2001)*

28. When the separation between two charges is increased, the electric potential energy of the system

(A) increases (B) decreases
(C) remains the same (D) may increase or decrease.

29. Three charges Q, $+q$ and $+q$ are placed at the vertices of a right angled isosceles triangle as shown. The net electrostatic energy of the configuration is zero, if Q is equal to

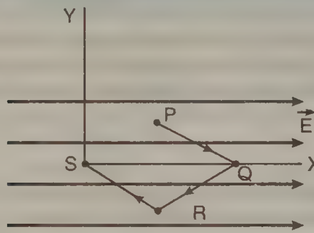


(A) $\frac{-q}{1+\sqrt{2}}$
(B) $\frac{-2q}{2+\sqrt{2}}$
(C) $-2q$
(D) $+q$ (I.I.T. 2000)

30. Which of the following quantities do not depend upon the choice of the zero of electric potential or zero of electric potential energy ?
(A) potential at a point.
(B) potential difference between two points.
(C) potential energy of a system of two point charges.
(D) change in potential energy of a system of two point charges.

31. Two identical thin rings, each of radius R metre are coaxially placed at distance R metre apart. If q_1 and q_2 coulomb are respectively the charges uniformly spread on two rings, the work done in moving a charge q from the centre of one ring to that of the other is
(A) zero
(B) $(\sqrt{2}-1)\,q\,(q_1-q_2)/\sqrt{2}\,4\pi\varepsilon_0 R$
(C) $\sqrt{2}\,q\,(q_1+q_2)/4\pi\varepsilon_0 R$
(D) $(\sqrt{2}+1)\,q\,(q_1+q_2)/\sqrt{2}\,4\pi\varepsilon_0 R$ (I.I.T. 1992)

32. Point charge q moves from point P to point S along th path PQRS (as shown in figure) in a uniform electric fiel



E pointing co-parallel to the positive direction of X-axi The cordinates of the points P, Q, R and S are $(a, b,$ $(2a, 0, 0)$, $(a, -b, 0)$ and $(0, 0, 0)$ respectively. The work don by the field in the above process is given by the expressio
(A) qEa (B) $-qEa$
(C) $qEa\sqrt{2}$ (D) $qE\sqrt{(2a)^2+b^2}$
(I.I.T. 198

33. A charge $+q$ is fixed at each of the points $x = x_0$, $x_0 = 3x$ $x = 5x_0$, ... to ∞ on the X-axis and a charge $-q$ is fixed each of the points $x = 2x_0$, $x = 4x_0$, $x = 6x_0$........ to ∞. Her x_0 is a positive constant. Take the electric potential at point due to a charge Q at a distance r from it to b $\frac{1}{4\pi\varepsilon_0}\cdot\frac{Q}{r}$. Then, the potential at the origin due to th above system of the charges is :
(A) 0 (B) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{q}{2x_0\log_e 2}$
(C) ∞ (D) $\frac{1}{4\pi\varepsilon_0}\cdot\frac{q\log_e 2}{x_0}$
(I.I.T. 199

Chapter 4. Gauss's Theorem

PART I. TEXT-BASED QUESTIONS

1. The electric flux through a hemispherical surface of radius R placed in a uniform electric field E parallel to the axis of the circular plane is :
(A) $(2\pi R)E$ (B) $(\pi R^2)E$
(C) $\left(\frac{4}{3}\pi R^3\right)E$ (D) $\left(\frac{2}{3}\pi R^3\right)E$

2. A cylinder of length L and radius R is placed in a uniform electric field E parallel to the axis of the cylinder. The total electric flux for the surface of the cylinder is given by
(A) $(2\pi R^2)E$ (B) $(2\pi RL)E$
(C) $2\pi R(R+L)E$ (D) zero.

3. A point charge $+q$ is placed at the mid point of a cube of side L. The electric flux emerging from the cube is
(A) $\frac{q}{\varepsilon_0}$ (B) $\frac{q}{6L^2\varepsilon_0}$
(C) $\frac{6qL^2}{\varepsilon_0}$ (D) zero. (C.B.S.E. 1996, 1993)

4. A charge $q\ \mu$C is palced at the centre of a cube of side 0·1 m. Then the electric flux diverging from each face of this cube is
(A) $\frac{q\times10^{-6}}{24\varepsilon_0}$ (B) $\frac{q\times10^{-4}}{\varepsilon_0}$
(C) $\frac{q\times10^{-6}}{\varepsilon_0}$ (D) $\frac{q\times10^{-4}}{12\varepsilon_0}$ (C.B.S.E. 2001)

5. An electric charge q is placed at one of the corner of a cub of side a. The electric flux on one of its faces will be
(A) $q/a\varepsilon_0$ (B) $q/\varepsilon_0 a^2$
(C) $q/4\pi\varepsilon_0 a^2$ (D) $\frac{q}{24\varepsilon_0}$ (C.B.S.E. 2000, 199

6. Gauss's theorem :
(A) does not hold, if the closed surface encloses a discre distribution of charges.
(B) does not hold, if the closed surface encloses a line, surface or a volume charge distribution.
(C) holds, if the surface encloses a point charge only.
(D) holds, irrespective of the form in which charges a enclosed by the closed surface.

7. Electric field varies as r^{-3} due to :
(A) a point charge. (B) an infinite line charge.
(C) an electric dipole.
(D) an infinite plane sheet of charge.

8. Electric field varies as r^{-1} due to
(A) a point charge. (B) a quadrupole.
(C) an infinite line charge.
(D) an infinite plane sheet of charge.

9. The electric field inside a spherical shell of unifor surface charge density is
(A) zero. (B) uniform.
(C) non-uniform.
(D) proportional to distance from the centre.

10. A spherical shell of radius R has a charge $+q$ units. Th electric field due to the shell at a point :

(A) inside is zero and varies as r^{-1} outside it.
(B) inside is constant and varies as r^{-2} outside it.
(C) inside is zero and varies as r^{-2} outside it.
(D) inside is constant and varies as r^{-1} outside it.

A sphere of charge of radius R has uniform volume charge density. The electric field due to the sphere of charge at a point :
(A) inside varies as r^{-2} and as r outside it.
(B) inside varies as r and as r^{-2} outside it.
(C) inside is zero and varies as r outside it.
(D) inside is constant and varies as r^{-2} outside it

A hollow insulated conducting sphere is given a positive charge of 10 μC. What will be the electric field at the centre of the sphere, if its radius is 2 m ?
(A) zero (B) 5 μC m $^{-2}$
(C) 20 μC m $^{-2}$ (D) 32 μC m $^{-2}$
(C.B.S.E. 1998)

T II. THOUGHT-BASED QUESTIONS

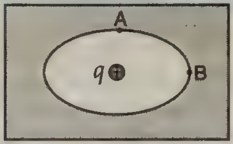
A charge q is placed at the corner of a cube of side a. The electric flux through the cube is :
(A) q/ε_0 (B) $q/3\varepsilon_0$
(C) $q/6\varepsilon_0$ (D) $q/8\varepsilon_0$

If the eletric flux through a closed surface is zero, then
(A) the electric field must be zero everywhere on the surface.
(B) the electric field may be zero everywhere on the surface.
(C) the charge inside the surface must be zero.
(D) the charge in the vicinity of the surface must be zero.

An electric dipole is placed inside a hollow sphere at its centre. Then,
(A) the electric flux through the sphere is zero.
(B) the electric field is zero at every point on the surface of the sphere.
(C) the electric field is non-zero at every point on the surface of the sphere.
(D) the electric field is non-zero at every point on the surface of the sphere.

A capacitor of capacitance C is charged to a potential V and is placed inside a closed surface. The electric flux through the closed surface is
(A) CV/ε_0 (B) $2CV/\varepsilon_0$
(C) $CV/2\varepsilon_0$ (D) zero

An ellipsoidal cavity is carved within a perfect conductor as shown in figure. A positive charge q is placed at the centre of the cavity. The points A and B are on the cavity surface. Then,
(A) electric field near A in the cavity = electric field near B in the cavity
(B) charge density at A = charge density at B



(C) potential at A = potential at B
(D) total electric field flux through the surface of the cavity is q/ε_0. *(I.I.T. 1999)*

18 **A metallic particle having no net charge is placed near a positively charged metal plate having finite size. The electric force on the particle will be**
(A) towards the plate. (B) away from the plate.
(C) parallel to the plate. (D) zero.

19. **If one penerates a uniformly charged sphere, the electric field strength E**
(A) increases. (B) decreases.
(C) remains the same as at the surface.
(D) is zero at all points. *(C.P.M.T. 1991, 1980)*

20. **A non-conducting solid sphere of radius R is uniformly charged. The magnitude of the electric field due to the sphere at a distance r from its centre**
(A) increases as r increases, for $r << R$.
(B) decreases as r increases, for $0 < r < \infty$
(C) decreases as r increases, for $R < r < \infty$.
(D) is discontinuous at $r = R$. *(I.I.T. 1998)*

21. **Potential at any point inside a charged hollow sphere**
(A) increases with distance.
(B) is a constant.
(C) decreases with distance from centre.
(D) is zero. *(Karnataka Entrance, 1990)*

22. **A hollow metal sphere of radius 5 cm is charged, such that the potential on its surface is 10 V. The potential at the centre of the sphere is**
(A) 0 V (B) 10 V
(C) same as at a point 5 cm away from the surface.
(D) same as at a point 25 cm away from the surface.
(M.N.R. 1990 ; I.I.T. 1983)

23. **A hollow sphere of charge does not produce an electric field at any**
(A) interior point (B) outer point
(C) beyond 2 m (D) beyond 10 m. *(M.N.R. 1985)*

24. **The force between the plates of a parallel plate capacitor of area A, capacitance C and having charge q will be**
(A) $q^2/2\varepsilon_0 A$ (B) $-q^2/2\varepsilon_0 A$
(C) $q^2/4\varepsilon_0 A$ (D) $-q^2/4\varepsilon_0 A$
(A.F.M.C. 1998)

Chapter 5. Capacitors

T I. TEXT-BASED QUESTIONS

In SI, unit of permittivity is :
(A) F m^{-1} (B) N m^2 C^{-2}
(C) N m^{-2} C^{-1} (D) A m^{-1}

The capacitance of the earth viewed as a spherical conductor of radius 6408 km is
(A) 980 μF (B) 1424 μF
(C) 712 μF (D) 600 μF *(C.P.M.T. 1992)*

N identical spherical drops charged to the same potential V are combined to from a big drop. The potential of the new drop will be
(A) V (B) V/N
(C) V N (D) V N$^{2/3}$ *(Karnataka, 2000)*

4. **A capacitor having capactiance of 2 μF has a charge of 1 μC on its plates. If the charge on the plates is changed to 2 μC, the new capacitance of the capacitor is**
(A) 4 μF (B) 2 μF
(C) 1 μF (D) 0· μF *(C.E.T. 1998)*

5. **A parallel plate capacitor is charged. If the plates are pulled apart,**
(A) the potential difference increases.
(B) the capacitance increases.
(C) the total charge increases.
(D) the charge and the potential difference remain the same.
(Karnataka Entrance , 1987)

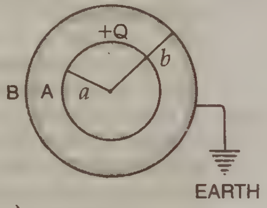
6. **The capacitance of a parallel plate capacitor increases with**
(A) decrease of its area.
(B) increase of its distance.

(C) increase of its area.
(D) decrease of its distance. *(A.F.M.C. 1995)*

7. **When air is replaced by a dielectric medium of constant K, the maximum capacitance of the capacitor**
(A) increases K times (B) remains unchanged
(C) increases K^2 times (D) decreases K times
(Karnataka Entrance ; 1994 ; N.C.E.R.T. 1990)

8. **A parallel plate capacitor with oil between the plates (dielectric constant of oil, K = 2) has a capacitance C. If the oil is removed, then capacitance of the capacitor becomes :**
(A) $\sqrt{2}\,C$ (B) 2 C
(C) $C/\sqrt{2}$ (D) C/2 *(C.B.S.E. 1999)*

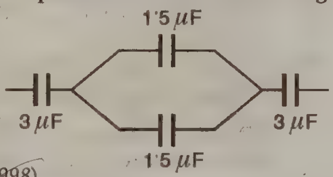
9. **Two spherical conductors A and B of radii *a* and *b* (*b* > *a*) are placed concentrically in air. A is given a charge + Q, while B is earthed. Then, the equivalent capacitance of the system is :**
(A) $4\pi\varepsilon_0 \frac{ab}{b-a}$
(B) $4\pi\varepsilon_0 (a+b)$
(C) $4\pi\varepsilon_0 b$
(D) $4\pi\varepsilon_0 \frac{b^2}{b-a}$



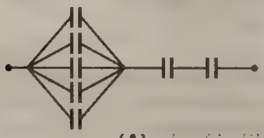
10. The magnitude of electric field $\vec{E}$ in the annular region of a charged cylindrical capacitor
(A) is same throughout.
(B) is higher near the outer cylinder than near the inner cylinder.
(C) varies as $\frac{1}{r}$, where r is the distance from the axis.
(D) varies as $\frac{1}{r^2}$, where r is the distance from the axis.
(I.I.T. 1996)

11. **There are 10 capacitors each of capacitance 5 μF. The ratio between maximum and minimum capacitance that can be obtained from these capacitors is :**
(A) 5 : 1 (B) 10 : 1
(C) 50 : 1 (D) 100 : 1

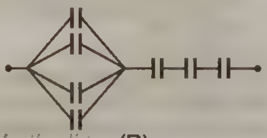
12. **What is the equivalent capacitance of the following circuit ?**
(A) 1 μF
(B) 2 μF
(C) 1·5 μF
(D) 3 μF *(A.F.M.C. 1998)*



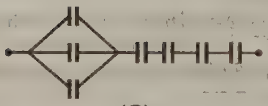
13. **Seven capacitors each of capacitance 2 μF are connected in a configuration to obtain an effective capacitance of $\frac{10}{11}$ μF. Which of the combination(s) shown in the figure will achieve the desired result ?**



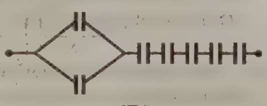
(A)



(B)



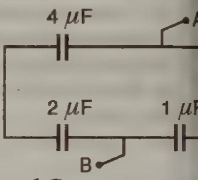
(C)



(D)

14. **Three identical capacitors (of capacitance C each)
connected in series and this connection is connecte
parallel with one such more identical capacitor. Then,
capacitance of the whole combination is**
(A) 3 C (B) $\frac{4}{3}$C
(C) $\frac{3}{4}$C (D) 2 C
(Karnataka Entrance, 1992, 1

15. **For the arrangement of the capacitors as shown in figure,
net capacitance between points
A and B is :**
(A) 1·7 μF
(B) 2·33 μF
(C) 2·8 μF
(D) 7 μF

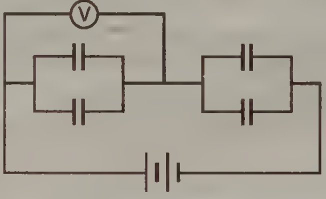


16. **Two capacitors of capacitances C_1 and C_2 are connecte
parallel. If a charge *q* is given to the assembly, the ch
gets shared. The ratio of the charge on the capacitor C
the charge that on C_2 is :**
(A) C_1/C_2 (B) C_2/C_1
(C) $C_1 C_2$ (D) $1/C_1 C_2$ *(I.I.T. 1*

17. **A capacitor of capacitance C_1 is charged upto potenti
and then connected in parallel to an uncharged capa
of capacitance C_2. The final potentail difference ac
each capacitor will be :**
(A) $\frac{C_2 V}{C_1 + C_2}$ (B) $\frac{C_1 V}{C_1 + C_2}$
(C) $\left(1+\frac{C_2}{C_1}\right)V$ (D) $\left(1-\frac{C_2}{C_1}\right)V$ *(C.B.S.E. 2*

18. **An isolated capacitor of unknown capacitance has b
charged to a potential difference of 100 V. When
charged capacitor is connected in parallel to an uncha
10 μF capacitor, the voltage across the combination is 3
The unknown capacitance is closer to**
(A) 1· 6 μF (B) 2 μF
(C) 4· 3 μF (D) 6· 2 μF *(C.E.T. 1*

19. **Four capacitors of 25 μF each are connected as show
figure. If the d.c. voltmeter reads 200 V, charge on each p
of the capacitor is :**



(A) 2×10^{-3} C (B) 5×10^{-3} C
(C) 2×10^{-2} C (D) 5×10^{-2} C *(C.B.S.E. 1*

20. **In a charged capacitor, the energy resides**
(A) on the positive plate.
(B) on both the positive and negative charged plates.
(C) in the field between the plates.
(D) around the edge of the capacitor plates.
(Karnataka 2000 ; J.I.P.M.E.R. 1

21. **The energy stored in a capacitor of capacitance C
potential V is given by**
(A) $\frac{1}{2}C^2 V$ (B) $\frac{1}{2}C V^2$
(C) $\frac{1}{2}C V$ (D) $\frac{1}{2}C^2 V^2$ *(C.B.S.E. 1*

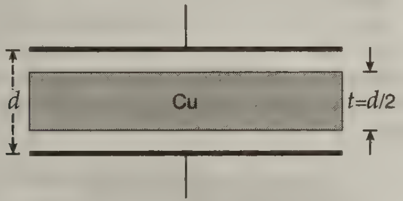
2. **700 pF capacitor is charged by a 50 V battery. How much electrostatic energy is stored by it ?**
(A) $6{\cdot}7 \times 10^{-7}$ J (B) $8{\cdot}7 \times 10^{-7}$ J
(C) $13{\cdot}6 \times 10^{-9}$ J (D) $17{\cdot}0 \times 10^{-8}$ J
(A.F.M.C. 1997)

3. **A capacitor of capacitance 10 μF was originally charged to 10 V. Now, the potential difference is increased to 20 V. The increase in potential energy is**
(A) 4×10^{-4} J (B) 10×10^{-4} J
(C) 15×10^{-4} J (D) 5×10^{-4} J *(C.E.T. 1999)*

4. **Two identical capacitors are joined in parallel, charged to a potential V, separated and then are connected in series *i.e.* the positive plate of one is connected to the negative of the other. Then,**
(A) the charges on the free plates connected together are destroyed.
(B) the charges on the free plates are enhanced.
(C) the energy stored in the system increases.
(D) the potential difference between the free plates becomes 2 V.
(Karnataka Entrance, 1993 ; N.C.E.R.T. 1973)

5. **A 4 μF capacitor is charged to 400 V. If its plates are joined through a resistance of 2 kΩ, then heat produced in the resistance is :**
(A) $0{\cdot}16$ J (B) $0{\cdot}32$ J
(C) $0{\cdot}64$ J (D) $1{\cdot}28$ J *(C.B.S.E. 1995, 1994)*

6. **A copper slab of thickness t is inserted between the plates of a parallel plate capacitor, such that t is half of the separation between the plates. The ratio of the capacitances of the capacitor before and after the introduction of the copper slab is :**



(A) 1 : 1 (B) $\sqrt{2}:1$
(C) $1:\sqrt{2}$ (D) 1 : 2

7. **A metal foil of negligible thickness is introduced between two plates of a capacitor at the centre. The capacitance of capacitor will be :**
(A) same (B) double
(C) half (D) K times *(I.I.T. 1982)*

8. **A parallel plate capacitor is charged and the charging battery is then disconnected. If the plates of the capacitor are moved further apart by means of insulating handles,**
(A) the charge on the capacitor increases.
(B) the voltage across the plates increases.
(C) the capacitance increases.
(D) the electrostatic energy stored in the capacitor increases. *(I.I.T. 1987)*

9. **A parallel plate air capacitor is connected to a battery. The quantities charge, voltage, electric field and energy associated with capacitor are given by Q_0, V_0, E_0 and U_0 respectively. A dielectric slab is now introduced to fill the space between the plates with battery still in connection. The corresponding quantities now given by Q, V, E and U are related to the previous ones as :**
(A) $Q > Q_0$ (B) $V > V_0$
(C) $E > E_0$ (D) $U > U_0$ *(I.I.T. 1985)*

0. **Van de Graaff generator is used to**
(A) measure high potential difference.
(B) produce high d.c. potential.
(C) produce high a.c. potential.
(D) compare high d.c. potential.
(Karnataka Entrance, 1992, 1989)

31. **The accumulation of charge on clouds, which produces lightning, is caused by**
(A) rain drops changing into electrons.
(B) the electric field of the earth.
(C) ionisation by the sun.
(D) electrification due to motion of water molecules.
(Karnataka Entrance 1985 ; similar 1987)

PART II. THOUGHT-BASED QUESTIONS

32. **In a guard ring capacitor, the purpose of the guard ring is**
(A) to increase the capacitance.
(B) to decrease the capacitance.
(C) to increase the effective area of the capacitor.
(D) to avoid the variation of the electric field intensity at the edges. *(Karnataka Entrance, 1992, 1989)*

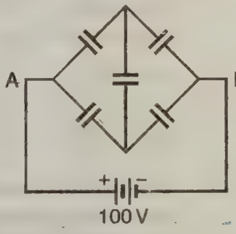
33. **Two identical metal plates are given positive charges q_1 and q_2 ($< q_1$) respectively. If they are now brought close together to form a parallel plate capacitor with capacitance C, the potential difference between them is**
(A) $(q_1 + q_2)/2\,C$ (B) $(q_1 + q_2)/C$
(C) $(q_1 - q_2)/C$ (D) $(q_1 - q_2)/2\,C$ *(I.I.T. 1999)*

34. **Two identical capacitors have the same capacitance C. One of them is charged to potential V_1 and the other to V_2. The negative ends of the capacitors are connected together. When the positive ends are also connected, the decrease in energy of the combined system is**
(A) $\frac{1}{4}C(V_1^2 - V_2^2)$ (B) $\frac{1}{4}C(V_1^2 + V_2^2)$
(C) $\frac{1}{4}C(V_1 - V_2)^2$ (D) $\frac{1}{4}C(V_1 + V_2)^2$ *(I.I.T. 2002)*

35. **Two capacitors with capacitances C_1 and C_2 are charged to potentials V_1 and V_2 respectively. When they are connected in parallel, the ratio of their respective charges is**
(A) C_1/C_2 (B) V_1/V_2
(C) V_1^2/V_2^2 (D) C_1^2/C_2^2 *(Karnataka, 2000)*

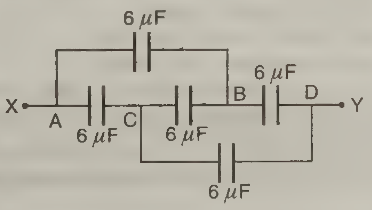
36. **A dielectric slab of thickness d is inserted in a parallel plate capacitor, whose negative plate is at $x = 0$ and positive plate is at $x = 3\,d$. The slab is equidistant from the plates. The capacitor is given some charge. As x goes from 0 to $3\,d$,**
(A) the magnitude of the electric field remains the same.
(B) the direction of the electric field remains the same.
(C) the electric potential increases continuously.
(D) the electric potential increases at first, then decreases and again increases. *(I.I.T. 1998)*

37. **Five capacitors each of 10 μF capacitance are connected as shown to a source of e.m.f. The equivalent capacitance between points A and B is :**



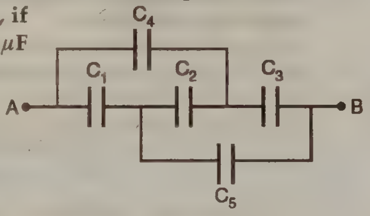
(A) 40 μF
(B) 20 μF
(C) 30 μF
(D) 10 μF
(C.E.T. 1999 ; C.P.M.T. 1991, 1988)

38. **What is the effective capacitance between points X and Y ?**



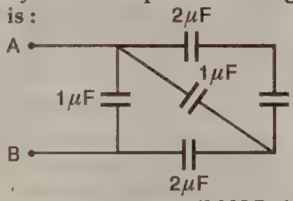
(A) 24 μF (B) 18 μF
(C) 12 μF (D) 6 μF (*C.B.S.E. 1999*)

39. Find the effective capacitance between points A and B in the following figure, if $C_1 = C_3$, $C_0 = C_5 = 4\ \mu F$ and $C_2 = 10\ \mu F$:



(A) 8 μF
(B) 6 μF
(C) 2·5 μF
(D) 4 μF

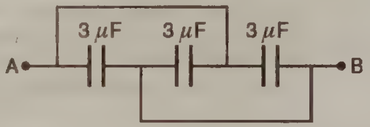
40. The net capacitance of system of capacitors in figure between points A and B is :



(A) 1 μF
(B) 2 μF
(C) 3 μF
(D) 4 μF

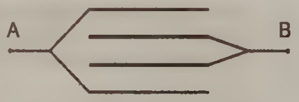
(*M.N.R. 1987*)

41. The equivalent capacitance between the points A and B in the following figure will be :



(A) 9 μF
(B) 1 μF
(C) 4·5 μF
(D) 6 μF (*C.P.M.T. 1985*)

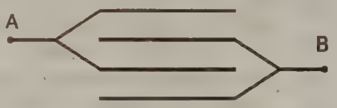
42. Four metallic plates each with a surface area of one side A are placed at a distance *d* apart from each other. The two inner plates are connected to point B and the other two plates to another point A as shown in figure. Then, the capacitance of the system is :



(A) $\frac{\varepsilon_0 A}{d}$ (B) $\frac{2\varepsilon_0 A}{d}$

(C) $\frac{3\varepsilon_0 A}{d}$ (D) $\frac{4\varepsilon_0 A}{d}$

43. Four metallic plates, each with a surface area of one side A are placed at a distance *d* from each other. The alternate plates are connected to points A and B as shown in figure. The equivalent capacitance of the system will be :



(A) $\frac{\varepsilon_0 A}{d}$ (B) $\frac{2\varepsilon_0 A}{d}$

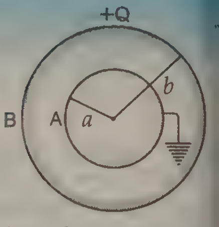
(C) $\frac{3\varepsilon_0 A}{d}$ (D) $\frac{4\varepsilon_0 A}{d}$

44. A solid sphere and a hollow sphere of equal diameters are raised to the same potential. Then,

(A) hollow sphere has more charge.
(B) both have equal charge.
(C) only hollow sphere has charge.
(D) solid sphere has more charge.

(*Karnataka Entrance, 1994 ; similar I.I.T. 1974*)

45. Two spherical conductors A and B of radii *a* and *b* (*b* > *a*) are placed concentrically in air. B is given a charge + Q and A is earthed. The equivalent capacitance of the system is :



(A) $4\pi\varepsilon_0 \frac{ab}{b-a}$

(B) $4\pi\varepsilon_0 (a+b)$

(C) $4\pi\varepsilon_0 b$

(D) $4\pi\varepsilon_0 \frac{b^2}{b-a}$

46. A capacitor is charged by connecting a battery across i plates. It stores energy U. Now the batery is disconnecte and another identical capacitor is connected across it. The the energy stored by both capacitors of the system will b

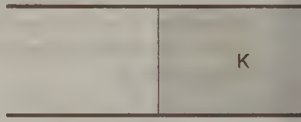
(A) U (B) U/2
(C) 2 U (D) 3 U/2 (*C.B.S.E. 200*

47. In a parallel plate capacitor, the distance between the plate is *d* and potential difference across plates is V. Energ stored per unit volume between the plates of capacitor i

(A) $\frac{Q^2}{2V^2}$ (B) $\frac{1}{2}\varepsilon_0 \frac{V^2}{d^2}$

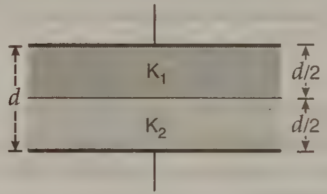
(C) $\frac{1}{2}\frac{V^2}{\varepsilon_0 d^2}$ (D) $\frac{1}{2}\varepsilon_0 \frac{V^2}{d}$ (*C.B.S.E. 200*

48. A dielectric is placed inbetween the two parallel plates c a capacitor as shown in figure. The dielectric constant c the dielectric is K. If the initial capacitance is C, then modified capacitance will be



(A) K C
(B) (K+1) C
(C) (K+1) C/2
(D) (K – 1) C

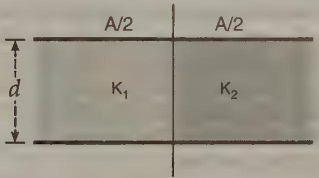
49. A parallel plate capacitor with plate area A and separatio *d* is filled with dielectrics as shown. Its capacitance wi become



(A) $\frac{\varepsilon_0 A}{d}(K_1 + K_2)$ (B) $\frac{\varepsilon_0 A}{d}\left(\frac{K_1 + K_2}{K_1 K_2}\right)$

(C) $\frac{2\varepsilon_0 A}{d}\left(\frac{K_1 K_2}{K_1 + K_2}\right)$ (D) $\frac{2\varepsilon_0 A}{d}\left(\frac{K_1 + K_2}{K_1 K_2}\right)$

50. A parallel plate capacitor is filled with two dielectrics a shown. Area of each plate is A metre^2 and the separatio is *d* metre. The dielectric constants are K_1 and K respectively. Its capacitance in farad will be :



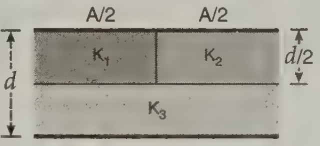
(A) $\frac{\varepsilon_0 A}{d}(K_1 + K_2)$ (B) $\frac{\varepsilon_0 A}{d}\left(\frac{K_1 + K_2}{2}\right)$

(C) $\frac{\varepsilon_0 A}{d}\frac{K_1 K_2}{K_1 + K_2}$ (D) $\frac{\varepsilon_0 A}{d}2(K_1 + K_2)$

A parallel plate capacitor with air as medium between the plates has a capacitance of 10 μF. The area of the capacitor is divided into two equal halves and filled with two media having dielectric constants 2 and 4 respectively. The modified capacitance is :

(A) 10 μF (B) 20 μF
(C) 30 μF (D) 40 μF

A parallel plate capacitor of area A , plate separation d and capacitance C is filled with three different dielectric materials having dielectric constants K_1, K_2 and K_3 as shown. If a single dielectric material is to be used to have the same capacitance C in this capacitor, then its dielectric constant K is given by

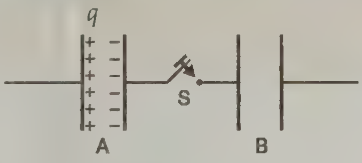


(A) $\frac{1}{K}=\frac{1}{K_1}+\frac{1}{K_2}+\frac{1}{2K_3}$ (B) $\frac{1}{K}=\frac{1}{K_1+K_2}+\frac{1}{2K_3}$

(C) $K=\frac{K_1K_2}{K_1+K_2}+2K_3$ (D) $K=K_1+K_2+2K_3$

(I.I.T. 2000)

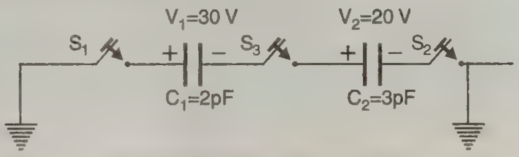
53. Consider the situation shown in the figure. The capacitor A has charge q on it, whereas B is uncharged. The charge appearing on the capacitor B a long time after the switch is closed, is :



(A) zero
(B) $q/2$
(C) q
(D) $2q$

(I.I.T. 2002)

54. For the circuit shown in figure, which of the following statements is true ?



(A) with S_1 closed, $V_1 = 15$ V, $V_2 = 20$ V.
(B) with S_3 closed, $V_1 = V_2 = 25$ V.
(C) with S_1 and S_2 closed, $V_1 = V_2 = 0$.
(D) with S_1 and S_3 closed, $V_1 = 30$ V, $V_2 = 20$ V.

(I.I.T. 1999)

CHAPTER 1

Electric Current, Resistance and E.M.F.

1.01. ELECTRIC CURRENT

It is defined as the rate of flow of electric charge through any section of a wire. It is noted by I. Thus,

$$I = \frac{\text{total charge flowing}}{\text{time taken}}$$

If charge q flows in a time t through any section of a wire, then

$$I = \frac{q}{t} \qquad ...(1.01)$$

If charge dq flows through a wire in small time dt, then

$$I = \frac{dq}{dt}$$

If n carriers of electricity, each having charge e cross any section of the conductor ime t, then

$$I = \frac{n\,e}{t} \qquad ...(1.02)$$

The direction in which the positive charge will flow gives the direction of *ventional current*. However, in metallic conductors, free electrons are carriers electricity and hence electrons constitute the electric current. Therefore, the ection of electronic current is opposite to that of conventional current.

Although, a direction is associated with electric current, yet it is a scalar antity. The reason is that the laws of ordinary algebra are used to add electric rent. The laws of vector algebra do not apply to the addition of electric currents.

Unit of electric current. The SI unit of electric current is **ampere.** It is also the ctical unit of current. It is denoted by **A.**

$$\textbf{1 ampere (A)} = \frac{\textbf{1 coulomb (C)}}{\textbf{1 second (s)}} = \textbf{1 coulomb second}^{-1}\ (\mathbf{C\ s^{-1}})$$

The current through a wire is called one ampere, if one coulomb of charge flows through wire in one second.

The jargon .....

The current that flows from a point at higher (positive) potential to a point at lower (negative) potential is called conventional current.

Watch out !

The electric current has both magnitude and direction but it is not a vector quantity !

Self-test question ?

How many electrons crossing per second through any section of a conductor constitute a current of one ampere ?

1.02. DRIFT VELOCITY

In a conductor, the atoms are quite close to each other and are strongly bound one another. However, valence electrons in an atom of a conductor donot remain ached to a particular atom. These electrons are free to move through the lattice ositive ions in the conductor. Such valence electrons in a conductor are called *e electrons* or *conduction electrons*. The free electrons in a conductor are always a continuous random motion [Fig. 1.01]. This random motion of free electrons is e to thermal energy of the conductor. Likewise, the velocity of a free electron due hermal energy of the conductor is termed as its thermal velocity and is usually y large.

Further, the number of free electrons in a conductor is very large. Due to their dom motion, the free electrons keep on sufferring collisions with the positive s in the conductor so frequently that the net flow of electrons in any particular ection is zero. In other words, average thermal velocity of free electrons in a nductor is zero.

If $\vec{u}_1, \vec{u}_2, \vec{u}_3, \ldots, \vec{u}_n$ are random thermal velocities of n electrons in a nductor, then their average thermal velocity *i.e.*

$$\frac{\vec{u}_1 + \vec{u}_2 + \vec{u}_3 + \ldots.. \vec{u}_n}{n} = 0 \qquad ...(1.03)$$

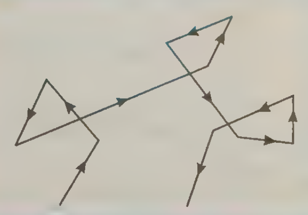

Fig. 1.01

Key point ✓

The thermal velocities of free electrons are of the order of 10^5 m s^{-1}.

Key point ✓

If we consider one free electron per atom, then number of free electrons in 1 m^3 of a conductor is about 10^{29}.

However, when some potential difference is applied across the two ends of a conductor, an electric field is set up. If V is potential difference applied and l, the length of the conductor [Fig. 1.02], then magnitude of the electric field set up is given by

$$E = \frac{V}{l}$$

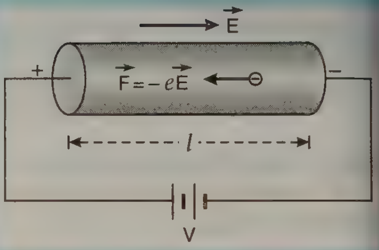

Fig. 1.02

The direction of electric field is from positive end of the conductor to its negative end as shown in the figure. Since charge on an electron is $-e$, each free electron in the conductor experiences a force

$$\vec{F} = -e\,\vec{E} \qquad \text{...(1.04)}$$

in a direction opposite to the direction of electric field. If m is mass of the electron, then acceleration produced is given by

$$\vec{a} = -\frac{e\,\vec{E}}{m} \qquad \text{...(1.05)}$$

Under the effect of electric field, the free electrons accelerate and acquire a velocity component in a direction opposite to the direction of electric field in addition to their thermal velocities. However, the gain in velocity of an electron due to electric field takes place only for a very short time. It is because, as the electron accelerates, it gets scattered or deflected on suffering collision against the positive ion in the conductor. The electron, then starts afresh with a random thermal velocity.

The short time, for which a free electron accelerates before it undergoes a collision with the positive ion in the conductor, is called ***relaxation time****.*

Therefore, if an electron having random thermal velocity $\vec{u}_1$ accelerates for a time t_1 (before it suffers a collision), then it will attain a velocity

$$\vec{v}_1 = \vec{u}_1 + \vec{a}\,\tau_1$$

where the acceleration $\vec{a}$ is given by equation (1.05). Similarly, velocities acquired by the other electrons in the conductor will be

$$\vec{v}_2 = \vec{u}_2 + \vec{a}\,\tau_2,\ \vec{v}_3 = \vec{u}_3 + \vec{a}\,\tau_3, \ldots\ldots, \vec{v}_n = \vec{u}_n + \vec{a}\,\tau_n$$

The drift velocity is defined as the average velocity with which free electrons in a conductor get drifted under the influence of an external electric field applied across the conductor. It is denoted by $\vec{v}_d$. Thus,

$$\vec{v}_d = \frac{\vec{v}_1 + \vec{v}_2 + \vec{v}_3 + \ldots\ldots + \vec{v}_n}{n}$$

$$= \frac{(\vec{u}_1 + \vec{a}\,\tau_1) + (\vec{u}_2 + \vec{a}\,\tau_2) + (\vec{u}_3 + \vec{a}\,\tau_3) + \ldots\ldots + (\vec{u}_n + \vec{a}\,\tau_n)}{n}$$

or $$\vec{v}_d = \frac{\vec{u}_1 + \vec{u}_2 + \vec{u}_3 + \ldots\ldots + \vec{u}_n}{n} + \vec{a}\,\frac{\tau_1 + \tau_2 + \tau_3 + \ldots\ldots + \tau_n}{n}$$

Now, $\frac{\tau_1 + \tau_2 + \tau_3 + \ldots\ldots + \tau_n}{n}$ is called ***average relaxation time*** and is denoted by τ. As obtained in equation (1.03), $\frac{\vec{u}_1 + \vec{u}_2 + \vec{u}_3 + \ldots\ldots + \vec{u}_n}{n}$ is equal to zero. Therefore, the above equation becomes

Key point

The random motion of free electrons does not contribtue to their drift velocity.

$$\vec{v}_d = 0 + \vec{a}\,\tau = \vec{a}\,\tau$$

Using equation (1.05), we have

$$\vec{v}_d = -\frac{e\,\vec{E}}{m}\,\tau \qquad \text{...(1.06)}$$

The equation (1.06) gives drift velocity of free electrons in a conductor in terms of electric field and average relaxation time.

1.03. RELATION BETWEEN DRIFT VELOCITY AND ELECTRIC CURRENT

Consider a conductor of length l and uniform area of cross-section A. Then,

volume of conductor = A l

Suppose that the conductor contains n free electrons per unit volume. Then, number of free electrons in the conductor = $n\,A\,l$

If e is charge on an electron, then total charge on all the free electrons in the onductor,

$$q = n\,A\,l\,e \qquad ...(1.07)$$

When a battery is connected across the two ends of the conductor, an electric ield $\vec{E}$ is set up across the two ends of the conductor as shown in Fig. 1.03. If the lectrons drift towards the positive end of the conductor with drift velocity v_d, then ime taken by the free electrons to cross the length of the conductor,

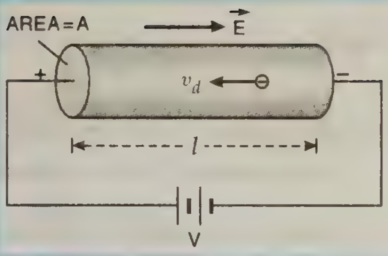

Fig. 1.03

$$t = \frac{l}{v_d} \qquad ...(1.08)$$

Since current is defined as the rate of flow of charge through the conductor,

$$I = \frac{q}{t}$$

Using equations (1.07) and (1.08), we have

$$I = \frac{n\,A\,l\,e}{l/v_d}$$

or

$$I = n\,A\,v_d\,e \qquad ...(1.09)$$

The equation (1.09) gives the relation between drift velocity of free electrons nd the current flowing through the conductor.

Note. From equation (1.06), the magnitude of drift velocity is given by

$$v_d = \frac{e\,E}{m}\,\tau$$

Substituting for v_d in equation (1.09), we get

$$I = \frac{n\,A\,e^2\,\tau}{m}\,E \qquad ...(1.10)$$

1.04. ELECTRON MOBILITY

The mobility of free electrons in a conductor is defined as the drift velocity acquired er unit strength of the electric field applied across the conductor. It is denoted by μ.

If v_d is drift velocity attained by free electrons on applying electric field E, then lectron mobility is given by

$$\mu = \frac{v_d}{E} \qquad ...(1.11)$$

Substituting for v_d (= μE) in equation (1.09), we have

$$I = n\,A\,\mu\,E\,e \qquad ...(1.12)$$

The equation (1.12) gives the relation between electron mobility and the current hrough the conductor.

From equation (1.11), it follows that in SI, the unit of electron mobility is **metre^2 olt^{-1} second^{-1}** ($\mathbf{m^2\,V^{-1}\,s^{-1}}$).

1.05. ELECTRIC CURRENT AND CURRENT DENSITY

Consider that a current I is flowing through a conductor of area of cross-section A. The current through the conductor can be defined in terms of a vector quantity $\vec{j}$ alled ***current density.*** If the current flowing through the conductor is uniform over ts cross section, then current may be defined as

$$I = \vec{j}\,.\,\vec{A}, \qquad ...(1.13)$$

here $\vec{A}$ is area vector representing the area of cross-section of the conductor. In case he current flowing through the conducor is not uniform over its cross-section, then he current through a small area $d\vec{A}$ of the conductor is given by

$$dI = \vec{j}\,.\,d\vec{A}$$

Hence, the current through the whole cross-section of the conductor is given y

$$I = \int \vec{j}\,.\,d\vec{A} \qquad ...(1.14)$$

Further, in case current density $\vec{j}$ is normal to the cross-sectional area of the conductor *i.e.* is $\hat{j}$ is parallel to $\vec{A}$, then

$$I = j A$$

or $$j = \frac{I}{A} \qquad ...(1.15)$$

From equation (1.09), substituting for I, we have

$$j = n v_d e \qquad ...(1.16)$$

Also, from equation (1.10) and (1.15), we have

$$j = \frac{n e^2 \tau}{m} E \qquad ...(1.17)$$

1.06. OHM'S LAW

It is the most fundamental law of electricity and was given by George Simon Ohm in 1828.

It states that *the physical conditions (temperature, mechanical strain, etc) remaining unchanged, the current flowing through a conductor is always directly proportional to the potential difference across its two ends.* Mathematically,

$$V \propto I$$

or $$V = R I, \qquad ...(1.18)$$

where the constant of proportionality R is called the ***electrical resistance*** or simply ***resistance*** of the conductor. Its value depends upon the nature of conductor, its dimensions and the physical conditions. It is independent of the values of V and I. The graph between potential difference (V) applied across a conductor and the current (I) flowing through it is a straight line as shown in Fig. 1.04.

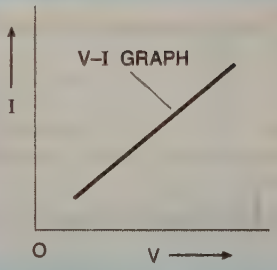

Fig. 1.04

1.07. RESISTANCE OF A CONDUCTOR

Resistance of a conductor is defined as the ratio of the potential difference applied across the conductor to the current flowing through it. Mathematically,

$$R = \frac{V}{I}$$

Unit of resistance. The SI unit of resistance is **ohm.** It is denoted by Ω.

$$\mathbf{1\ ohm\ (\Omega) = \frac{1\ volt\ (V)}{1\ ampere\ (A)}\ 1\ volt\ ampere^{-1}\ (V\ A^{-1})}$$

The resistance of a conductor is said to be one ohm, if one ampere of current flows through it, when a potential difference of one volt is applied across it.

Cause of resistance. The resistance of a conductor implies the opposition, which the conductor offers to the flow of charge through it. When a potential difference is applied across a conductor, an electric field is set up across its two ends. Due to this, the free electrons get accelerated. As the electrons move, they collide against the ions and atoms and their motion is thus opposed. This opposition offered by the ions and atoms is termed as the resistance of the conductor.

The jargon ......

A potential difference may be taken as the energy lost by 1 C of charge, as it moves through a resistor,

$$1\ V = 1\ J\ C^{-1}$$

The jargon ......

Ohmic conductors are those, which obey Ohm's law.

1.08. FAILURE OF OHM'S LAW

Ohm's law is not a fundamental law of nature. In many cases, the relation

$$V = R I$$

is not strictly obeyed and they lead to the failure of Ohm's law. A few cases are as explained below :

1. ***Current may vary non-linearly with potential difference.*** For a metallic conductor, graph between V and I is expected to be a straight line. However, the graph does not remain so, when the current is continuously increased through the conductor [Fig. 1.05]. The reason is that as current is increased, the temperature of the conductor rises and its resistance increases. The dotted straight line represents the theoretical curve, while the thick curve represents the actual V – I graph for a metallic conductor.

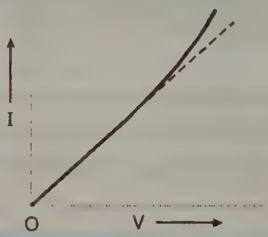

Fig. 1.05

2. ***The variation of current with potential difference may depend upon sign of the potential difference applied.*** For a semiconductor diode or *p-n* junction*, the variation of current is different, when the sign of potential difference applied across it is changed. When positive terminal of a battery is connected to *p*-section and negative terminal to the *n*-section (forward bias), the variation of current with

---

* For details about $p-n$ junction, refer to Unit IX.

ential difference is much more rapid than what it is when applied in opposite nner (reverse bias). It is as shown in Fig. 1.06.

It may be noted that in case of a semiconductor, the variation of current with ential difference is non-linear in addition to the fact that magnitude of variation ends upon the sign of potential difference applied across it.

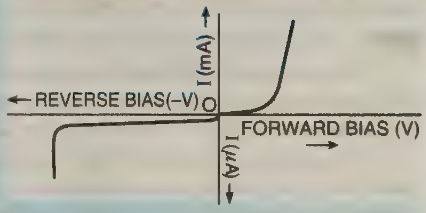

Fig. 1.06

3. ***The current may decrease on increasing the potential difference.*** A thyristor sists of four alternate layers of p and n-type semiconductors. The V – I graph th for forward and reverse bias) of a thyristor is of the type as shown in Fig. 1.07. portion AB of the graph shows that current increases on decreasing the potential erence. It may be noted that in addition to the fact that current increases with rease in potential difference for a thyristor, the current varies non-linearly with ential difference and also the magnitude of the variation of current depends upon sign of the potential difference applied across it.

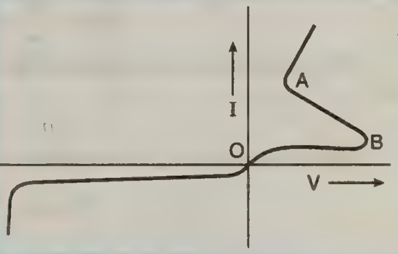

Fig. 1.07

1.09. RESISTIVITY

The resistance of a conductor depends upon the following factors :

(*i*) *It is directly proportional to the length of the conductor i.e.*

$$R \propto l$$

(*ii*) *It is inversely proportional to the area of cross-section of the conductor i.e.*

$$R \propto \frac{1}{A}$$

Combining the above two factors, we have

$$R \propto \frac{l}{A}$$

or

$$R = \rho \frac{l}{A} \qquad ...(1.19)$$

ere the constant of proportionality ρ is called ***electrical resistivity*** or ***specific stance*** of the conductor. Its value depends upon the nature of the material of conductor and its temperature. The equation (1.19) gives the resistance of a ductor in terms of its length, area of cross-section and resistivity of the material.

If $l = 1$, $A = 1$, then $R = \rho \frac{1}{1}$ or $\rho = R$

Hence, *resistivity or specific resistance of the material of a conductor is the resistance red by a wire of this material of unit length and unit area of cross-section.*

Unit of resistivity. From equation (1.19), we have

$$\rho = R \frac{A}{l}$$

In SI, unit of resistivity $= \text{ohm} \times \frac{\text{metre}^2}{\text{metre}} = \text{ohm metre}$

Therefore, SI unit of resistivity is **ohm metre (Ω m).**

The electrical resistivity of substances varies over a very wide range as given he following table :

MATERIAL	RESISTIVITY AT 0°C (Ω m)	MATERIAL	RESISTIVITY AT 0°C (Ω m)
(*a*) **Conductors :**		(*c*) **Semiconductors :**	
Silver	1.6×10^{-8}	**Carbon**	3.5×10^{-5}
Copper	1.7×10^{-8}	**Germanium**	0.46
Aluminium	2.7×10^{-8}	**Silicon**	2300
Tungsten	5.6×10^{-8}		
Iron	10×10^{-8}	(*d*) **Insulators**	
Platinum	11×10^{-8}	**Wood**	$10^8 - 10^{11}$
Mercury	98×10^{-8}	**Glass**	$10^{10} - 10^{14}$
(*b*) **Alloys :**		**Amber**	$5 - 10^{14}$
Manganin	44×10^{-8}	**Mica**	$10^{11} - 10^{15}$
Constantan	49×10^{-8}		
Nichrome	100×10^{-8}		

The first column lists the electrical resistivity of metals. It follows that metals ve low resistivities and they are called *conductors* of electricity. In the second umn, materials such as glass and hard rubber are about 10^{22} to 10^{24} times more istive than silver and copper. These are called *insulators*. Materials like carbon, germanium and silicon having resistivity in between those of conductors and insulators are called *semiconductors*.

1.10. FACTORS AFFECTING ELECTRICAL RESISTIVITY

The concept of average relaxation time helps in a great deal to understand the nature of electrical resistance. In order to do so, let us derive expression for resistance of a conductor in terms of average relaxation time (τ), electron density (n), etc.

Consider a conductor having length l and area of cross-section A. Let n be number of electrons per unit volume in the conductor. If an electric field E is applied across the two ends of the conductor, then drift velocity (in magnitude) of electrons is given by

$$v_d = \frac{e\,\mathrm{E}}{m}\tau$$

The current flowing through the conductor due to drift of electrons is given by

$$\mathrm{I} = n\,\mathrm{A}\,v_d\;e$$

Substituting for v_d in the above equation, we have

$$\mathrm{I} = n\,\mathrm{A}\left(\frac{e\,\mathrm{E}}{m}\tau\right)e$$

or

$$\mathrm{I} = \frac{n\,\mathrm{A}\,e^2\,\mathrm{E}\,\tau}{m} \qquad \text{...(1.20)}$$

If V is potential difference applied across the two ends of the conductor, then

$$\mathrm{E} = \frac{\mathrm{V}}{l}$$

Substituting for E in equation (1.20), we have

$$\mathrm{I} = \frac{n\,\mathrm{A}\,e^2\,\mathrm{V}\,\tau}{m\,l}$$

or

$$\frac{\mathrm{V}}{\mathrm{I}} = \frac{m\,l}{n\,e^2\,\tau\,\mathrm{A}}$$

But according to Ohm's law, $\frac{\mathrm{V}}{\mathrm{I}} = \mathrm{R}$, the resistance of the conductor.

$$\therefore \qquad \mathrm{R} = \frac{m}{n\,e^2\,\tau}\cdot\frac{l}{\mathrm{A}} \qquad \text{...(1.21)}$$

Comparing the above result with the expression for resistance obtained earlier *i.e.*

$$\mathrm{R} = \rho\frac{l}{\mathrm{A}},$$

it follows that resistivity of the material of a conductor is given by

$$\rho = \frac{m}{n\,e^2\,\tau} \qquad \text{...(1.22)}$$

It follows that resistivity of the material of a conductor depends on the following factors :

1. *It is inversely proportional to the number of free electrons per unit volume* (n) *of the conductor.* Since the value of n depends upon nature of the material, *the resistivity of a conductor depends upon the nature of the material.*

2. *It is inversely proportional to the average relaxation time* (τ) *of the free electrons in the conductor.* As we shall study in next section, the value of τ decreases with increase in temperature of the conductor. Since $\rho \propto \frac{1}{\tau}$, the *resistivity of conductor depends upon its temperature and it increases with increase in temperature of the conductor.*

Resistivity in terms of current density. From equation (1.17), we have

$$\frac{m}{n\,e^2\tau} = \frac{\mathrm{E}}{j}$$

Therefore, equation (1.22) becomes

$$\rho = \frac{\mathrm{E}}{j} \qquad \text{...(1.23)}$$

The equation (1.23) gives the relation between current density and resistivity of the material of the conductor.

Resistivity in terms of electron mobility. From equation (1.16), substituting in equation (1.23), we have

$$\rho = \frac{E}{n\,e\,v_d} \qquad ...(1.24)$$

Substituting for v_d (= μ E) in equation (1.24), we have

$$\rho = \frac{1}{n\,e\,\mu} \qquad ...(1.25)$$

The equation (1.25) gives the relation between resistivity of the material of a ductor and the electron mobility.

Note. From equation (1.24), we have

$$v_d = \frac{E}{n\,e\,\rho}$$

Since $E = \frac{V}{l}$, the above equation becomes

$$v_d = \frac{V}{n\,e\,l\,\rho} \qquad ...(1.26)$$

The equation (1.26) can be used to predict the effect of temperature and length e conductor on drift velocity of electrons.

(a) Effect of temperature. On increasing the temperature of a conductor, the e of resistivity of its material increases. Therefore, from equation (1.26), it follows *drift velocity of electrons decreases on increasing the temperature of the conductor.*

(b) Effect of length of conductor. From equation (1.26) it follows that *drift velocity ectrons decreases, when length of the conductor is increased.*

1.11. CONDUCTANCE AND CONDUCTIVITY

Conductance. *The reciprocal of resistance of a conductor is called its conductance.* It is denoted by G. Thus, conductance of a conductor having resistance R is n by

$$G = \frac{1}{R} \qquad ...(1.27)$$

The SI unit of conductance is **ohm^{-1}** (Ω^{-1}), which is also called **mho.** In SI, the of conductance is also called **siemen** and is denoted by the symbol **S.**

Conductivity. *The reciprocal of resistivity of the material of a conductor is called its uctivity.* It is denoted by σ. Thus,

$$\sigma = \frac{1}{\rho} \qquad ...(1.28)$$

From equations (1.23) and (1.28), it follows that

$$\sigma = \frac{j}{E} \qquad ...(1.29)$$

The equation (1.29) gives the relation beween conductivity and current density.

From equations (1.25), and (1.28), we have

$$\sigma = n\,e\,\mu \qquad ...(1.30)$$

The equation (1.30) gives the relation between conductivity of the material of nductor and the electron mobility.

From equation (1.28), it follows that unit of conductivity is reciprocal of the of resistivity. Therefore, in SI, the unit of conductivity is **ohm^{-1} metre^{-1} m^{-1})** or **mho metre^{-1}** or **siemen metre^{-1} (S m^{-1}).**

1.12. TEMPERATURE DEPENDENCE OF RESISTIVITY

The variation of resistivity of a metallic conductor, an alloy, a semi-conductor n insulator with increase in temperature is not same in all the cases.

Temperature dependence of the resistivity of a metallic conductor. In terms elaxation time, the resistivity of the material of a conductor is given by

$$\rho = \frac{m}{n\,e^2\,\tau},$$

re the letters have their usual meanings.

It follows that the resistivity of a conductor is inversely proportional to the age relaxation time of the free electrons in the conductor. The average relaxation is not a constant parameter. It changes with change of temperature of the ductor.

If the temperature of the conductor increases, the amplitude of the vibrations of the positive ions in the conductor also increases. Due to this, the free electrons collide more frequently with the vibrating ions and as a result, the average relaxation time decreases. Since $\rho \propto \frac{1}{\tau}$, the resistivity of the material of a conductor increases with increase of temperature.

For pure conductors such as copper, the resistivity increases linearly with temperature in the temperature range around and above the room temperature. If ρ_0 and ρ are resistivity of the material of a conductor at 0°C and θ°C respectively, then it is found that

$$\rho = \rho_0 (1 + \alpha \theta) \qquad ...(1.31)$$

Here, α is called ***temperature coefficient of resistivity***. It may be pointed out that at low temperature, the resistivity of pure conductors increases as a higher power of temperature.

Since $R = \rho \frac{l}{A}$, from the equation (1.31), it follows that

$$R = R_0 (1 + \alpha \theta) \qquad ...(1.32)$$

or

$$\alpha = \frac{R - R_0}{R_0 \times \theta} \qquad ...(1.33)$$

Here, R_0 and R_θ represent resistance of the conductor at 0°C and θ°C respectively. As such, α may also be called as ***temperature coefficient of resistance*** of the conductor.

Thus, resistivity of a conductor increases linearly with increase of temperature and vice versa. As temperature of a pure metallic conductor approaches 0 K, its resistivity also approaches zero. For metals, value of α lies between 10^{-2} to 10^{-4} °C^{-1}.

2. Temperature dependence of the resistivity of an alloy. In the case of an alloy, such as nichrome, the resistivity is very large and it has a very weak dependence on temperature. For example, manganin, which is an alloy of copper, nickel, iron and manganese has a resistance which is thirty to forty times as that of pure copper for the same dimensions but its temperature coefficient is very small *i.e.* 0·00001 °C^{-1}. For this reason, it is an excellent substance to be used for the construction of a standard resistance coil.

Key point

The resistivity of conductors increase that of semiconductors decreases increase of temperature.

3. Temperature dependence of the resistivity of a semi-conductor and insulator. The variation of resistivity with temperature in case of a semi-conductor or an insulator is different from that in case of a conductor. Whereas, in case of a conductor, the resistivity varies linearly with temperature of the conductor, the resistivity of a semi-conductor and an insulator has an exponential dependence on temperature. In case of a semi-conductor and an insulator, the resistivity at temperature T (in kelvin) is given by

$$\rho = \rho_0 \, e^{E_g/kT} \qquad ...(1.34)$$

Here, k is Boltzmann's constant and E_g is called energy gap between valence and conduction bands in the atoms of such materials. It may be noted that both semiconductors and insulators are non-conducting materials at low temperatures. The division of non-conducting materials into semiconductors and insulators is purely on the basis of the size of the value of E_g in two cases. In case of a semi-conductor, $E_g \le 1$ eV or so and likewise the resistivity of a semiconductor at room temperature is not very high. On the other hand, in case of an insulator, E_g is of the order of several eV and hence at room temperature, resistivity of an insulator is extremely high. At 0 K, both the semiconductor and an insulator have infinite value of the resistivity.

1.13. THERMISTORS

A thermistor is a heat sensitive resistor usually made of a semi conducting material, such that its resistance varies appreciably with change in temperature.

A thermistor differs from an ordinary resistance in the following ways :

1. The resistance of a thermistor changes very rapidly with change of temperature.
2. The temperature coefficient of a thermistor is very high.
3. The temperature coefficient of a thermistor can be both positive and negative.

The thermistors having negative temperature coefficients find a variety of plications in practice.

Thermistors are made from the oxides of semi-conductors. They are generally he form of beads, discs or rods. A pair of platinum leads are attached at the two ds for electric connections. The arrangement is enclosed in a small glass bulb and led. The size of a thermistor is very small.

Depending upon the composition, a thermistor may have resistance in the range ·1 Ω to 10^7 Ω. The thermistors can be used over a wide range of temperature *i.e.* m a very low temperature to about 1100°C. The change in the value of a thermistor be caused either due to change in temperature of its surroundings or by the wer dissipated in it on the passage of current.

Applications. Some of the important applications of thermistors are as given ow :

1. Due to their rapid response to temperature changes, thermistors are used detect small temperature change and to measure very low temperature (≈ 10 K).

2. Thermistors are used in temperature control units and for detecting excessive nperature within an industrial equipments.

3. Thermistors are used in the protection of windings of motors, transformers d generators.

4. Thermistors are used to safeguard the heater of the picture tube of a television against variation in current.

5. Thermistors are used for voltage stabilisation, temperature control and note sensing.

.14. SUPER-CONDUCTIVITY

The phenomenon, due to which a substance loses all signs of its resistance, when cooled ts critical temperature, is called ***superconductivity.***

The substances, which offer superconductivity (no resistance) are called ***perconductors.***

Explanation. When the temperature of a conductor is lowered, its resistance creases. In other words, a conductor becomes a better conductor as the nperature is lowered. There was speculation that resistance of a conductor will imately become zero at 0 K.

The boiling points of liquid oxygen, liquid nitrogen and liquid hydrogen are pectively –183° C, –196° C and –263° C. Therefore, the temperature up to which decrease in resistance with decrease of temperature could be studied was –263° e. 10 K. Ultimately, K. Onnes succeeded in liquefying helium gas and its boiling int was found to be 0·7 K. In 1911, K. Onnes studied the variation of resistivity solid mercury (it solidifies at–39° C) and he found that its resistivity kept on creasing in a normal manner with decrease in temperature but at 4·2 K, its istivity suddenly became zero [Fig. 1.08]. Thus, at 4·2 K, all signs of resistance appear in case of mercury *i.e.* it becomes superconductor. In case of mercury, this nperature of 4·2 K is called its ***critical temperature.***

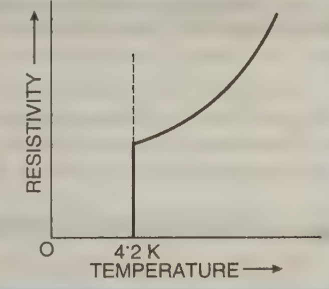

Fig. 1.08

Superconductivity is exhibited by a large number of metals and alloys. It has en discovered that alloys of niobium and tin, and of niobium and zirconium show perconductivity up to a temperature of 18 K. Today, there are thousands of perconductors with ***critical temperature*** (the temperature at which the resistivity ddenly drops to zero) as high as 23 K. Scientists all over the world are trying to nieve superconductivity at room temperature.

The cause of superconductivity is that electrons in a superconductor are tually coherent. The ionic vibrations, which could deflect free electrons in metals, unable to deflect the coherent cloud of electrons in superconductors.

Key point ✓

The conductivity of metals and alloys increases, as they are cooled. At critical temperature, their resistivity becomes zero and they behave as superconductors.

Applications (or uses) of superconductors. At present, superconductivity has en achieved in case of a few metals and alloys only at very low temperature. As ch, the superconductors so developed find their use in research work only. The y superconductivity is achieved at room temperature, the superconductors will come of very striking and interesting uses. A few of them are as below :

1. They will help to produce superfast computers.

2. It will be possible to transmit electrical power without any loss of electrical ergy by using superconducting cables.

3. Superconductors will enable to produce very high magnetic field without y expenditure of electrical power.

1.15. COLOUR CODE FOR CARBON RESISTANCES

The value of resistances used in electric and electronic circuits vary over a very wide range. Such high resistances used are usually carbon resistances and the values of such resistances are marked on them according to a colour code.

A carbon resistance has usually four rings or bands A, B, C and D of different colours [Fig. 1.09]. The colours of first two bands A and B indicate the first two significant figures of the resistance in ohm, while the colour of third band C indicates the decimal multiplier. The colour of fourth band D (which is either silver or gold) tells the *tolerance* of the resistance. If the colour of fourth band is silver or gold, then tolerance of the resistance is 10% and 5% respectively. Sometimes, there are only three colour bands A, B and C to indicate the value of the resistance. Since there is no fourth colour band, the tolerance of such a resistance is not indicated. The tolerance of such a resistance is 20%.

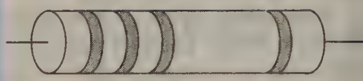

Fig. 1.09

To read the value of a carbon resistance, the following sentence serves as an aid to memory :

B B R O Y Great Britain Very Good Wife

The bold face letters in the above sentence (B, B, R, O, Y, G, B, V, G and W) correspond to the colours Black, Brown, Red, Orange, Yellow, Green, Blue, Violet, Grey and White respectively. The colours of first two bands A and B correspond to figures 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 and the colour of the third band C corresponds to multipliers 10^0, 10^1, 10^2, 10^3, 10^4, 10^5, 10^6, 10^7, 10^8 and 10^9 respectively. If the colour of the fourth band is gold, the tolerance is 5% and in case the colour is silver, the tolerance is 10%. In case, there is no fourth band, then its tolerance is 20%.

The following table gives the colour code for carbon resistance :

Letter as an aid to memory	Colour	Figure	Multiplier	Colour	Tolerance
B	Black	0	10^0	Gold	5%
B	Brown	1	10^1	Silver	10%
R	Red	2	10^2	No colour	20%
O	Orange	3	10^3		
Y	Yellow	4	10^4		
G	Green	5	10^5		
B	Blue	6	10^6		
V	Violet	7	10^7		
G	Grey	8	10^8		
W	White	9	10^9		

For example, consider a carbon resistance, for which the bands A, B and C are of colours brown, green and orange respectively and the last band D is of silver in colour. The value of the resistance can be found from the table as explained below :

Corresponding to colours of bands A and B, which are brown and green, the figures are 1 and 5. Corresponding to the third band of orange colour, the multiplier is 10^3. Therefore, resistance is of the value $15 \times 10^3\ \Omega$. Since silver colour of the fourth band corresponds to a tolerance of 10%, the value of the given resistance is

$$R = 15 \times 10^3\ \Omega \ \pm 10\%$$

1.16. RESISTORS IN SERIES

Two or more resistors are said to be connected in series, if same current passes through each of them, when some potential difference is applied across the combination.

The jargon . . . . .

An electric component that offers ohm
resistance to the flow of current is calle
a resistor.

Fig. 1.10 shows the series combination of three resistors having resistances R_1, R_2 and R_3. If a battery of e.m.f. E is connected across the series combination, the same current I will pass through each of them. If V_1, V_2 and V_3 are the values of potential difference across R_1, R_2 and R_3 respectively, then according to Ohm's law,

$$V_1 = I R_1 ;\ V_2 = I R_2 \text{ and } V_3 = I R_3$$

Also, $$E = V_1 + V_2 + V_3$$

$\therefore$ $$E = I R_1 + I R_2 + I R_3$$

or $$E = I (R_1 + R_2 + R_3) \qquad ...(1.35)$$

If R_s is resistance equivalent to the series combination of R_1, R_2 and R_3, then resistance R_s will allow the same current I to flow through it, when the battery of e.m.f. E is connected across it. Therefore,

$$E = I R_s \qquad ...(1.36)$$

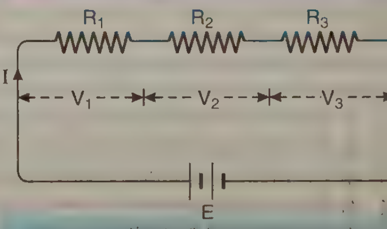

Fig. 1.10

om equations (1.35) and (1.36), we have

$$I R_s = I (R_1 + R_2 + R_3)$$

$$R_s = R_1 + R_2 + R_3 \qquad (1.37)$$

us, *when the resistors are connected in series, equivalent resistance of the series tion is equal to the sum of individual resistances.*

s obvious that the value of equivalent resistance of the series combination ys greater than the value of the largest individual resistance. Therefore, s are connected in series, if the resistance in the circuit is to be increased.

series resistance circuit, it should be remembered that

he current through all the resistors is same.

he total resistance of the circuit is equal to the sum of individual resistances including resistance of the cell, if any.

he potential difference across any resistor is proportional to its resistance.

he current in the circuit is independent of the relative positions of the various resistors rcuit.

Key point

In series combination of resistors,
(*i*) current through all the resistors is same and
(*ii*) potential difference across a resistor is proportional to its resistance.

Key point

The equivalent resistance of a series combination of resistors is always greater than the largest resistance in the combination. Therefore, resistors are connected in series in order to increase the resistance of the circuit.

17. RESISTORS IN PARALLEL

o or more resistors are said to be connected in parallel, if potential difference across hem is equal to the applied potential difference.

. 1.11 shows the parallel combination of three resistors having resistances nd R_3. If a battery of e.m.f. E is connected across the parallel combination, ntial difference across each resistor will be equal to E, the e.m.f. of the battery. and I_3 are values of the current through the resistances R_1, R_2 and R_3 vely, then current in main circuit is given by

$$I = I_1 + I_2 + I_3 \qquad ...(1.38)$$

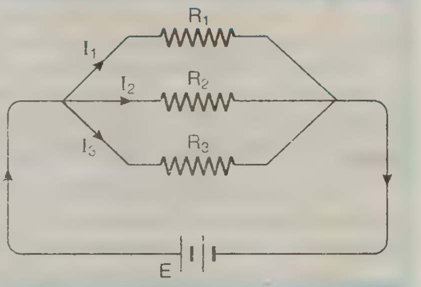

Fig. 1.11

w, the potential difference across each resistor is E. Therefore, applying aw, we have

$$E = I_1 R_1 = I_2 R_2 = I_3 R_3$$

$$I_1 = \frac{E}{R_1}\ ;\ I_2 = \frac{E}{R_2} \text{ and } I_3 = \frac{E}{R_3}$$

erefore, equation (1.38) becomes

$$I = \frac{E}{R_1} + \frac{E}{R_2} + \frac{E}{R_3}$$

$$I = R\left(\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}\right) \qquad ...(1.39)$$

Key point

In parallel combination of resistors,
(*i*) potential difference across all of them is same and
(*ii*) current through any resistor is inversely proportional to its resistance.

R_p is resistance equivalent to the parallel combination of R_1, R_2 and R_3 *i.e.* if stance R_p allows the same current I to flow through it, when the battery of is connected across it, then

$$E = I R_p$$

$$I = \frac{E}{R_p} \qquad ...(1.40)$$

om equations (1.39) and (1.40), we have

$$\frac{E}{R_p} = E\left(\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}\right)$$

$$\frac{1}{R_p} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} \qquad ...(1.41)$$

us, *when resistors are connected in parallel, reciprocal of equivalent resistance of llel combination is equal to the sum of the reciprocals of individual resistances.*

may be pointed out that the value of equivalent resistance is always less than e of the smallest individual resistance. Therefore, resistors are connected lel, if the resistance in the circuit is to be decreased.

a parallel resistance circuit, it should be remembered that

otal current through the parallel combination is equal to the sum of individual through the various resistors.

he potential difference across all the resistors is same.

the current through any resistor is inversely proportional to its resistance.

he reciprocal of the total resistance of the combination is equal to the sum of the ls of individual resistances.

Key point

The equivalent resistance of a parallel combination of resistors is always less than the smallest resistance in the combination. Therefore, resistors are connected in parallel in order to decrease the resistance of the circuit.

1.18. INTERNAL RESISTANCE AND ELECTROMOTIVE FORCE OF THE CELL

Internal resistance of a cell. When a cell is connected in a circuit, it drives the charge in the circuit. The rate of flow of charge is termed as current. When the current flows through the cell, its electrolyte offers resistance to the flow of current. It is because of the fact that ions have to move against the background of other ions and the neutral atoms.

The resistance offered by the electrolyte of the cell, when the electric current flows through it, is known as internal resistance of the cell. It is denoted by r.

For a freshly prepared cell, the value of internal resistance is very low, but as the cell is put to more and more use, its internal resistance goes on increasing.

Electromotive force (e.m.f.). *The potential difference between the two poles of the cell in an open circuit (when no current is drawn from the cell) is called the electromotive force (e.m.f.) of the cell.*

Due to its e.m.f., a cell drives the charge round the circuit. Therefore, *e.m.f. of a cell is also defined as the energy supplied by the cell to drive a unit charge round the complete circuit.* It is denoted by E.

In SI, the unit of e.m.f. is **volt (V)** or **joule coulomb^{-1} (J C^{-1}).**

The e.m.f. of a cell is called one volt, if 1 joule of work is performed by the cell to drive one coulomb of charge round the circuit.

Note. It may be pointed out that the word electromotive force (e.m.f.) is misnomer. It does not represent force on the carriers of electricity. Instead, it represents the work done per unit charge to drive the carriers of electricity.

1.19. TERMINAL POTENTIAL DIFFERENCE OF A CELL

Terminal potential difference. *The potential difference between the two poles of a cell in a closed circuit (when current is drawn from the cell) is called the terminal potential difference of the cell.* It is denoted by V. Its unit is same as that of e.m.f.

When current flows through the circuit, there is fall of potential across the internal resistance of the cell. The potential difference between the two poles of the cell is less than the e.m.f. of the cell by an amount equal to potential drop across the internal resistance. Therefore, the terminal potential difference of a cell is always less than its e.m.f.

Expression for internal resistance. Let us consider a cell of e.m.f. E and internal resistance r connected to an external resistance R and a one way key K as shown in Fig. 1.12. A voltmeter V of high resistance is connected across the poles of the cell.

When the circuit is open (plug not inserted in the key), no current flows through the circuit. Therefore, from the definition of the e.m.f., the reading of the voltmeter is equal to E, e.m.f. of the cell.

Now, close the key [Fig. 1.13]. The current will flow through the circuit. Since internal resistance (r) of the cell and the external resistance (R) are in series, the total resistance in the circuit is (R + r).

According to Ohm's law, the current in the circuit is given by

$$I = \frac{E}{R + r} \qquad \text{...(1.42)}$$

Since current is drawn from the cell on closing the key, according to the definition of terminal potential difference, the reading of the voltmeter connected across the two poles of the cell is equal to the terminal potential difference between its two poles. The terminal potential difference V is less than e.m.f. E of the cell by an amount equal to potential drop across the internal resistance of the cell *i.e.*

$$V = E - I r \qquad (1.43)$$

Here, I r is the potential drop across internal resistance of the cell. It is also called ***lost volt***.

If no current is drawn from the cell *i.e.* I = 0, then from equation (1.43), we have

$$V = E - 0\,(r) = E$$

Hence, the terminal potential difference between the two poles of a cell is equal to its e.m.f., if no current is drawn from it.

Also, terminal potential difference is equal to potential differences across external resistance R *i.e.*

$$V = I R \qquad \text{...(1.44)}$$

Watch out !

Though called force, electromotiv
does not represent force. It repr
work done per unit charge !

The jargon . . . . .

E.M.F. of a cell (in volt) is energy
by 1 C of charge as it passes thro

Self-test Question

Why is there no way to separate th
nal resistance from the e.m.f. of a

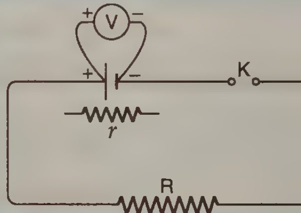

Fig. 1.12

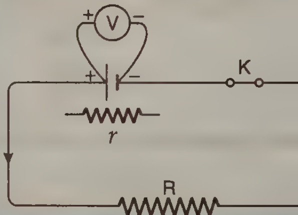

Fig. 1.13

Key point

(*i*) When a current I flows ***out*** of
terminal potential difference,

$$V = E - I r$$

i.e. potential drop across interna
tance ***opposes*** the e.m.f.

(*ii*) When a current I flows ***into***
terminal potential difference,

$$V = E + I r$$

i.e. potential drop across interna
tance ***aids*** the e.m.f.

From equations (1.42) and (1.44), we have

$$V = \frac{E}{R+r} R \quad \text{or} \quad r = \frac{R-V}{V} R$$

or $$r = \left(\frac{E}{V} - 1\right) R \qquad \text{...(1.45)}$$

It is expression for internal resistance of the cell in terms of e.m.f. and terminal ntial difference.

Key point

The potential drop across internal resistance of the cell is called ***lost volt***.

1.20. GROUPING OF CELLS

From a single cell, only a limited amount of current can be drawn. In many riments, the current required may be much more than that can be supplied by gle cell. In order to have a large value of current, the cells are usually connected ries or in parallel or the cells are mixed grouped.

1.21. CELLS IN SERIES

Fig. 1.14. shows a combination of n cells each of e.m.f. E and internal resistance nected in series so as to send current through an external resistance R. For series bination, the negative terminal of the first cell is connected to the positive inal of the second, the negative terminal of the second cell to the positive inal of the third and so on.

When the cells are connected in series, the total e.m.f. of the series combination ual to the sum of the e.m.fs. of the individual cells. Thus,

the total e.m.f. of the cells = nE

As the internal resistances of the cells also come in series,

the total internal resistance of the cells = $r + r + r + \ldots$ n times = nr

Therefore, total resistance of the circuit = $R + nr$

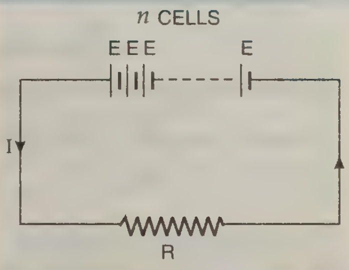

Fig. 1.14

Fig. 1.15 shows the effective e.m.f. and the internal resistance in the circuit, when ells are connected in series.

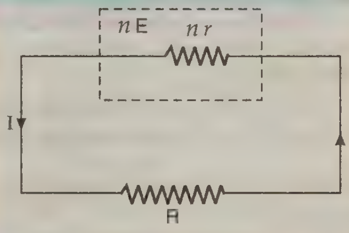

Fig. 1.15

If I is current flowing through the circuit, then

$$I = \frac{\text{total e.m.f.}}{\text{total resistance}}$$

or $$I = \frac{nE}{R + nr} \qquad \text{...(1.46)}$$

1. ***When R < < n r.*** In such a case,

$$R + nr \approx nr$$

Therefore, equation (1.46) becomes

$$I = \frac{nE}{nr} = \frac{E}{r} = \text{current due to single cell}$$

2. ***When R > > n r.*** In such a case,

$$R + nr \approx R$$

Therefore, equation (1.46) becomes

$$I = \frac{nE}{R} = n \text{ times the current due to a single cell}$$

From the above discussion, it may be concluded that *in order to have maximum nt, the cells should be connected in series, when the total internal resistance of the cells gligible as compared to the external resistance in the circuit.*

Key point

When n indentical cells are connected in series,

(*i*) e.m.f. of the combination becomes n times the e.m.f. of a single cell.

(*ii*) internal resistance of the combination becomes n times the internal resistance of a single cell.

Therefore, when external resistance of the circuit is very large, the cells should be connected in series so as to obtain maximum current.

1.22. CELLS IN PARALLEL

Consider that m cells each of e.m.f. E and internal resistance r are connected rallel so as to send current through the external resistance R as shown in Fig.

The cells are connected in parallel by connecting the positive terminals of all ells to one end of the external resistance and the negative terminals of all the to the other end of the external resistance.

When the cells are connected in parallel, the total e.m.f. of the parallel bination remains equal to the e.m.f. of a single cell. Therefore,

the total e.m.f. of the cells = E

As the internal resistance of the cells also come in parallel, the total internal tance r' of the cells is given by

$$\frac{1}{r'} = \frac{1}{r} + \frac{1}{r} + \frac{1}{r} + \ldots m \text{ times}$$

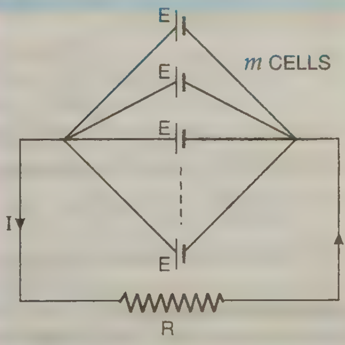

Fig. 1.16

or $$r' = \frac{r}{m}$$

Fig. 1.17 shows the effective e.m.f. and the internal resistance in the circuit, when the cells are connected in parallel.

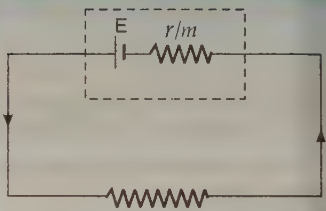

Fig. 1.17

If I is current flowing through the circuit, then

$$I = \frac{\text{total e.m.f.}}{\text{total resistance}} = \frac{R}{R + r'}$$

or $$I = \frac{E}{R + r/m} \qquad \text{...(1.47)}$$

1. ***When R > > r/m.*** In such a case,

$$R + r/m \approx R$$

Therefore, equation (1.47) becomes

$$I = \frac{E}{R} = \text{current due to single cell}$$

2. ***When R < < r/m.*** In such a case,

$$R + r/m \approx r/m$$

Therefore, equation (1.47) becomes

$$I = \frac{E}{r/m} = m\frac{E}{r} = m \text{ times current due to a single cell}$$

From the above discussion, it may be concluded that *in order to have maximum current, the cells should be connected in parallel, when the external resistance in the circuit is negligible as compared to the total internal resistance of the cells.*

Key point

When m identical cells are conencte
parallel,
(*i*) e.m.f. of the combination is equa
that of a single cell.
(*ii*) internal resistance of the combina
becomes $\frac{1}{m}$ th of the internal resistanc
a single cell.
Therefore, when external resistance in
circuit is negligible, the cells shoul
connected in parallel so as to obtain m
mum current.

1.23. MIXED GROUPING OF CELLS

When the external resistance of the circuit is of the same order as the internal resistance of the cells, then a large value of current is obtained by mixed grouping of the cells.

Fig. 1.18 shows N cells each of e.m.f. E and internal resistance r arranged in m rows, each row having n cells. Obviously,

$$N = m\,n$$

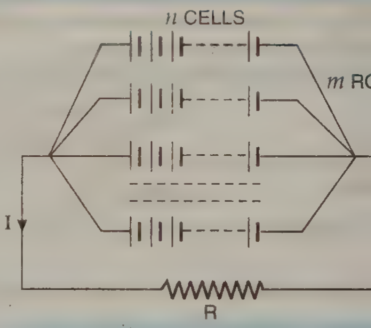

Fig. 1.18

This series-parallel combination of the cell sends current through an external resistance R.

Now, total e.m.f. of the cells = total e.m.f. of the cells connected in a row = n E

The internal resistance of the cells connected in a row = $n\,r$

Since there are such m rows, the total internal resistance of the cells is given by

$$\frac{1}{r'} = \frac{1}{n\,r} + \frac{1}{n\,r} + \frac{1}{n\,r} + \ldots.. + m \text{ times } = \frac{m}{n\,r}$$

or $$r' = \frac{n\,r}{m}$$

Fig. 1.19 shows the effective e.m.f. and the internal resistance in circuit, when the cells are mixed grouped as said above.

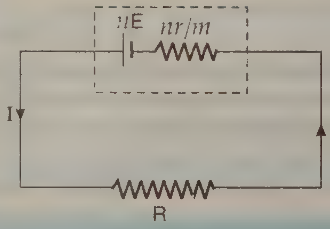

Fig. 1.19

$$\text{Total resistance of the circuit} = R + r' = R + \frac{n\,r}{m}$$

If I is current flowing through the circuit, then

$$I = \frac{n\,E}{R + n\,r/m} = \frac{m\,n\,E}{m\,R + n\,r} = \frac{N\,E}{m\,R + n\,r} \qquad (\because m\,n = N)$$

The current in the circuit will be maximum, if the factor in the denominator *i.e.* $m\,R + n\,r$ is minimum.

Now, $$m\,R + n\,r = (\sqrt{m\,R})^2 + (\sqrt{n\,r})^2 - 2\sqrt{m\,R}\,\sqrt{n\,r} + 2\sqrt{m\,R}\,\sqrt{n\,r}$$
$$= (\sqrt{m\,R} - \sqrt{n\,r})^2 + 2\sqrt{m\,n\,R\,r}$$

The R.H.S. of the above expression is sum of the two positive factors. Therefore, the factor $m\,R + n\,r$ will be minimum, if

$$\sqrt{m\,R} - \sqrt{n\,r} = 0 \quad \text{or} \quad m\,R = n\,r \quad \text{or} \quad R = \frac{n\,r}{m}$$

i.e. when external resistance in the circuit is equal to the total internal resistance of the cells.

From the above discussion, it follows that *in order to obtain maximum current, the cells should be mixed grouped in such a manner that the external resistance in the circuit is equal to the total internal resistance of the cells in mixed grouping.*

SOLVED NUMERICAL PROBLEMS

e A. On Definition of Current

Problem 1.01. How many electrons pass through a in one minute, if the current is 300 mA ? Given, charge ectron = 1.6×10^{-19} C.

(*P.S.S.C.E. 2002 ; H.P.S.S.C.E. 1995*)

Sol. Here, $I = 300 \text{ mA} = 300 \times 10^{-3}$; $e = 1.6 \times 10^{-19}$ C ;

$t = 1$ minute $= 60$ s

Charge passing through lamp in one minute,

$$q = I \times t = 300 \times 10^{-3} \times 60 \text{ C}$$

Suppose that n electrons pass through the lamp in one te. If e is charge on an electron, then

$$q = n\,e$$

or
$$q = \frac{n}{e} = \frac{300 \times 10^{-3} \times 60}{1.6 \times 10^{-19}} = 1.125 \times 10^{20}$$

Problem 1.02. In hydrogen atom, electron revolves nd the nucleus along a path of radius 0·51 Å making 10^{15} revolutions per second. Calculate the equivalent nt. Given charge on electron = 1.6×10^{-19} C.

Sol. Here, $e = 1.6 \times 10^{-19}$ C ; $\nu = 6.8 \times 10^{15}$ revolutions s^{-1} ;

$r = 0.51 \text{ Å} = 0.51 \times 10^{-10}$ m

f T is time period of electron, then it crosses a point on cular path after T seconds. Hence, equivalent current,

$$I = \frac{e}{T} = e\,\nu = 1.6 \times 10^{-19} \times 6.8 \times 10^{15}$$
$$= 1.088 \times 10^{-3} \text{ A}$$

e B. On Drift velocity

Problem 1.03. A current of 10 A is maintained in a uctor of cross-section 10^{-4} m^2. If the number density ee electrons be 9×10^{28} m^{-3}, calculate the drift ity of free electrons. Given that charge on electron, × 10^{-9} C.

Sol. Here $I = 10$ A ; $n = 9 \times 10^{28}$ m^{-3} ; $A = 10^{-4}$ m^2

and $e = 1.6 \times 10^{-19}$C

Now,
$$v_d = \frac{I}{n\,e\,A} = \frac{10}{9 \times 10^{28} \times 1.6 \times 10^{-19} \times 10^{-4}}$$
$$= 6.94 \times 10^{-6} \text{ m s}^{-1}$$

Problem 1.04. The number density of conduction rons in a copper conductor is 8.5×10^{28} m^{-3}. How long an electron take to drift from one end of a wire 3·0 m to its other end ? The area of cross-section of the wire × 10^{-6}m^2 and it is carrying a current of 3·0 A.

(*Text Problem*)

Sol. Here, $n = 8.5 \times 10^{28}$ m^{-3} ; $I = 3.0$ A ;

$A = 2.0 \times 10^{-6}$ m^2 ; $l = 3.0$ m

We know that charge on electron, $e = 1.6 \times 10^{-19}$ C

Now, drift velocity of electrons,

$$v_d = \frac{I}{n\,e\,A} = \frac{3.0}{8.5 \times 10^{28} \times 1.6 \times 10^{-19} \times 2.0 \times 10^{-6}}$$
$$= 1.103 \times 10^{-4} \text{ m s}^{-1}$$

Therefore, time taken by electron to drift from one end e other,

$$t = \frac{l}{v_d} = \frac{3.0}{1.103 \times 10^{-4}}$$
$$= 2.72 \times 10^4 \text{ s} = 7 \text{ hours and } 33 \text{ minutes}$$

Problem 1.05. Calculate the average drift velocity of conduction electrons in a copper wire of cross-section 10^{-7} m^2 carrying a current of 1 A. Assume that each copper atom contributes one conduction electron. Given that density of copper = 9×10^3 kg m^{-3} and its atomic mass = 63·5.

Sol. Here $A = 10^{-7}$ m^2 ; $I = 1$ A

Now, 63·5 g of copper contains atoms equal to Avogadro number *i.e.* 6.02×10^{23}.

Therefore, number of atoms in 1 kg of copper

$$= \frac{6.02 \times 10^{23}}{63.5} \times 1000$$

Since density of copper is 9×10^3 kg m^{-3}, number of atoms in 1 m^3 of copper

$$= \frac{6.02 \times 10^{23} \times 1000}{63.5} \times 9 \times 10^3 = 8.53 \times 10^{28}$$

As one copper atom contributes one conduction electron, number density of electron in copper is equal to number of atoms in 1 m^3 of copper *i.e.*

$$n = 8.53 \times 10^{28}$$

Hence, drift velocity of electrons,

$$v_d = \frac{I}{n\,e\,A} = \frac{1}{8.53 \times 10^{28} \times 1.6 \times 10^{-19} \times 10^{-7}}$$
$$= 7.33 \times 10^{-4} \text{ m s}^{-1}$$

Type C. On Electron mobility

Problem 1.06. A potential difference of 5 V is applied across a conductor of length 0·1 m. If drift velocity of electrons is 2.5×10^{-4} m s^{-1}, calculate the electron mobility.

Sol. Here, $V = 5$ volt ; $l = 0.1$ m ; $v_d = 2.5 \times 10^{-4}$ m s^{-1}

Electric field set up across the conductor,

$$E = \frac{V}{l} = \frac{5}{0.1} = 50 \text{ V m}^{-1}$$

Now, electron mobility,

$$\mu = \frac{v_d}{E} = \frac{2.5 \times 10^{-4}}{50} = 5 \times 10^{-6} \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1}$$

Problem 1.07. The number density of electrons in copper is 8.5×10^{28} m^{-3}. Find the current flowing through a copper wire of length 0·2 m, area of cross-section 1 mm^2, when connected to a battery of 3 V. Given that electron mobility = 4.5×10^{-6} m^2 V^{-1} s^{-1} and charge on electron = 1.6×10^{-19} C.

Sol. Here, $V = 3$ volt ; $l = 0.2$ m ; $A = 1 \text{ mm}^2 = 10^{-6} \text{ m}^2$;

$n = 8.5 \times 10^{28}$ m^{-3} ; $\mu = 4.5 \times 10^{-6}$ m^2 V^{-1} s^{-1}

and $e = 1.6 \times 10^{-19}$ C

Electric field set up across the conductor,

$$E = \frac{V}{l} = \frac{3}{0.2} = 15 \text{ V m}^{-1}$$

Now, current through the wire,

$$I = n\,A\,\mu\,E\,e = 8.5 \times 10^{28} \times 10^{-6} \times 15 \times 1.6 \times 10^{-19}$$
$$= 0.92 \text{ A}$$

Type D. On Current density

Problem 1.08. A current of 1·8 A flows through a wire of area of cross-section 0·5 mm^2. Find the current density

in the wire. If the number of density of electrons in the wire is $8{\cdot}8 \times 10^{28}$ m^{-3}, find the drift velocity of electrons.

Sol. Here, $I = 1{\cdot}8$ A ; $A = 1{\cdot}2$ mm^2 $= 0{\cdot}5 \times 10^{-6}$ m^2

and $n = 8{\cdot}8 \times 10^{28}$ m^{-3}

Now, current density,

$$j = \frac{I}{A} = \frac{1\cdot 8}{0\cdot 5 \times 10^{-6}} = \mathbf{3{\cdot}6 \times 10^6\ A\ m^{-2}}$$

Also, $j = n\, v_d\, e$

or $$v_d = \frac{j}{n\,e} = \frac{3\cdot 6 \times 10^6}{8\cdot 8 \times 10^{28} \times 1\cdot 6 \times 10^{-19}}$$

$$= \mathbf{2{\cdot}56 \times 10^{-4}\ m\ s^{-1}}$$

Problem 1.09. When a potential difference of 1·5 V is applied across a wire of length 0·2 m and area of cross-section 0·33 mm^2, a current of 2·4 A flows through the wire. If the number density of free electrons in the wire is $8{\cdot}4 \times 10^{28}$ m^{-3}, calculate the average relaxation time. Given that mass of electron = $9{\cdot}1 \times 10^{-31}$ kg and charge on electron = $1{\cdot}6 \times 10^{-19}$ C.

Sol. Here, $V = 1{\cdot}5$ V ; $n = 8{\cdot}4 \times 10^{28}$ m^{-3} ; $l = 0{\cdot}2$ m ;
$A = 0{\cdot}3$ mm^2 $= 0{\cdot}3 \times 10^{-6}$ m^2, $I = 2{\cdot}4$ A ;
$m = 9{\cdot}1 \times 10^{-31}$ kg and $e = 1{\cdot}6 \times 10^{-19}$ C

Electric field set up across the conductor,

$$E = \frac{V}{l} = \frac{1\cdot 5}{0\cdot 2} = 7\cdot 5\ \text{V m}^{-1}$$

The current density in the wire,

$$j = \frac{I}{A} = \frac{2\cdot 4}{0\cdot 3 \times 10^{-6}} = 8 \times 10^6\ \text{A m}^{-2}$$

Now, $$j = \frac{n\,e^2\,\tau}{m}\,E$$

Therefore, average relaxation time,

$$\tau = \frac{m\,j}{n\,e^2\,E} = \frac{9\cdot 1 \times 10^{-31} \times 8 \times 10^6}{8\cdot 4 \times 10^{28} \times (1\cdot 6 \times 10^{-19})^2 \times 7\cdot 5}$$

$$= \mathbf{4{\cdot}51 \times 10^{-16}\ s}$$

Type E. On Ohm's law

Problem 1.10. A potential difference of 200 volt is maintained across a conductor of resistance 100 ohm. Calculate the number of electrons flowing through it in one second. Charge on electron, $e = 1{\cdot}6 \times 10^{-19}$ C.

Sol. Here, V = 200 volt ; R = 100 ohm ; $e = 1{\cdot}6 \times 10^{-19}$ C

Now, $$I = \frac{V}{R} = \frac{200}{100} = 2\ \text{ampere}$$

Charge flowing in 1 s, $q = I\,t = 2 \times 1 = 2$ C

Therefore, number of electrons flowing through the conductor in 1 s,

$$n = \frac{q}{e} = \frac{2}{1\cdot 6 \times 10^{-19}} = \mathbf{1{\cdot}25 \times 10^{19}}$$

Type F. On Resistivity

Problem 1.11. Calculate the resistivity of the material of a wire 1·0 m long, 0·4 mm in diameter and having a resistance of 2·0 ohm. *(H.S.S.C.E. 2002 ; P.S.S.C.E. 1994)*

Sol. Here, $R = 2{\cdot}0\,\Omega$; $l = 1{\cdot}0$ m ;

diameter of wire, $d = 0{\cdot}4$ mm $= 4 \times 10^{-4}$ m

Therefore, area of cross-section of wire,

$$A = \frac{1}{4}\pi d^2 = \frac{1}{4}\pi \times (4 \times 10^{-4})^2 = 4\pi \times 10^{-8}\ \text{m}^2$$

If ρ is resistivity of the material of the wire, then

$$R = \rho\,\frac{l}{A}$$

or $$\rho = \frac{R\,A}{l} = \frac{2\cdot 0 \times 4\pi \times 10^{-8}}{1\cdot 0} = \mathbf{2{\cdot}153 \times 10^{-7}\ \Omega}$$

Problem 1.12. A wire having a mass of 0·4 possesses a resistance of 0·14 Ω. If the resistivity o material of wire is $1{\cdot}78 \times 10^{-8}$ Ω m, calculate its length radius. Given that density of the material of wire is 8 10^3 kg m^{-3}.

Sol. Here, $m = 0{\cdot}45$ kg ; $R = 0{\cdot}14\,\Omega$; $\rho = 1{\cdot}78 \times 10^{-8}$
and density of the material of wire, $d = 8{\cdot}93 \times 10^3$ kg

Let l be length and r be the radius of the wire.

Now, $$R = \rho\,\frac{l}{A} = \rho\,\frac{l}{\pi r^2}$$

Also, mass of the wire, m = volume × density

or $$m = \pi r^2\, l \times d$$

Multiplying equation (*i*) and (*ii*), we have

$$R \times m = \rho\,\frac{l}{\pi r^2} \times \pi r^2\, l \times d$$

or $$l = \sqrt{\frac{R\,m}{\rho\,d}} = \sqrt{\frac{0\cdot 14 \times 0\cdot 45}{1\cdot 78 \times 10^{-8} \times 8\cdot 93 \times 10^3}} = \mathbf{1{\cdot}}$$

From equation (*ii*), we have

$$r = \sqrt{\frac{m}{\pi\,l\,d}} = \sqrt{\frac{0\cdot 45}{\pi \times 1\cdot 99 \times 8\cdot 93 \times 10^3}}$$

$$= 2{\cdot}84 \times 10^{-3}\ \text{m} = \mathbf{2{\cdot}84\ mm}$$

Problem 1.13. A wire of resistance 5 ohm is draw so that its length is increased to twice its original le Calculate its new resistance.

(C.B.S.E. 1998 S ; H.P.S.S.C.E. 1

Sol. Let l be the length and A be the area of cross-sec of the wire. If ρ is the resistivity of its material, then

$$R = \rho\,\frac{l}{A}$$

Suppose that when length of the wire is increased (= 2 l), its area of cross-section becomes A′. As the volu the wire must remain the same, we have

$$A\,l = A'\,l' \qquad \text{or} \qquad A' = \frac{A\,l}{2\,l} = \frac{A}{2}$$

Let R′ be new resistance of the wire, then,

$$R' = \rho\,\frac{l'}{A'} = \rho\,\frac{2\,l}{A/2} = 4\,\rho\,\frac{l}{A}$$

From equation (*i*) and (*ii*), we have

$$R' = 4\,R = 4 \times 5 = \mathbf{20\ \Omega} \qquad (\because R =$$

Type G. On Conductance and conductivity

Problem 1.14. Calculate the electrical conductivi the material of a conductor of length 3 m, area of c section 0·2 mm^2 having a resistance of 2 ohm.

(C.B.S.E. 1

Sol. Here, $l = 3$; $A = 0{\cdot}02$ mm^2 $= 0{\cdot}02 \times 10^{-6}$ m^2 ; R =

Now, $$R = \rho\,\frac{l}{A} \qquad \text{or} \qquad \rho = \frac{R\,A}{l}$$

Also, conductivity of the wire, $\sigma = \dfrac{1}{\rho}$

or $$\sigma = \frac{l}{R\,A} = \frac{3}{2 \times 0\cdot 02 \times 10^{-6}} = \mathbf{7{\cdot}5 \times 10^7\ S}$$

blem 1.15. A wire carries a current of 1·2 A, when ial difference of 1·8 V is applied across it. What is uctance ? If the wire is of length 3 m and area of ction 5·4 × 10^{-6} m^2, calculate its conductivity.

. Here, $V = 1{\cdot}8\ V$; $I = 1{\cdot}2\ A$;

$l = 3$ m and $A = 5{\cdot}4 \times 10^{-6}\ m^2$

e resistance of wire, $R = \frac{V}{I} = \frac{1\cdot8}{1\cdot2} = 1\cdot5\ \Omega$

erefore, conductance of wire, $G = \frac{1}{R} = \frac{1}{1\cdot5} = \mathbf{0{\cdot}67\ S}$

w, $R = \rho\frac{l}{A}$ or $\rho = \frac{RA}{l}$

o, conductivity of wire, $\sigma = \frac{1}{\rho}$

$$\sigma = \frac{l}{RA} = \frac{3}{1\cdot5\times5\cdot4\times10^{-6}}$$

$= \mathbf{3{\cdot}7 \times 10^5\ S\ m^{-1}}$

. On Variation of resistance with temperature

blem 1.16. A wire has a resistance of 2·1 Ω at 300 a resistance of 2·7 Ω at 373 K. Determine the ture coefficient of resistance of the material.

(Pre-degree Kerala, 1991 ; Text Problem)

. Here, $R_1 = 2{\cdot}1\ \Omega$; $\theta_1 = 300$ K ; $R_2 = 2{\cdot}7\ \Omega$;

$\theta_2 = 373$ K

w, $$\alpha = \frac{R_2 - R_1}{R_1(\theta_2 - \theta_1)} = \frac{2\cdot7 - 2\cdot1}{2\cdot1\times(373-300)}$$

$= \mathbf{3{\cdot}194 \times 10^{-3}\ K^{-1}}$

blem 1.17. The resistance of a conductor is 6 Ω at d 7 Ω at 100°C. Calculate the mean temperature ent of resistance of the material. Find the resistance onductor at 0°C. *(Karnataka, 1983 S)*

. Here, $\theta_1 = 50°C$; $R_1 = 6\ \Omega$; $\theta_2 = 100°C$; $R_2 = 7\ \Omega$

an temperature coefficient of resistance of the

,

$$\alpha = \frac{R_2 - R_1}{R_1\times(\theta_2 - \theta_1)} = \frac{7-6}{6\times(100-50)}$$

$$= \frac{1}{6\times50} = \mathbf{\frac{1}{300}}\ °C^{-1}$$

$_0$ is resistance of the conductor at 0°C, then

$R_1 = R_0(1 + \alpha\,\theta)$

$$R_0 = \frac{R_1}{1+\alpha\,\theta} = \frac{6}{1+\frac{1}{300}\times50} = \frac{36}{7} = 5{\cdot}143\ W$$

blem 1.18. A heating element using nichrome ed to a 230 V supply draws an initial current of hich settles after a few seconds to a steady value of What is the steady temperature of the heating t, if the room temperature is 27°C ? Temperature ent of resistance of nichrome averaged over the ture range involved is 1·70 × 10^{-4} $°C^{-1}$.

(Text Problem)

.. Here, V = 230 volt ;

ial room temperature, $\theta_1 = 27°C$

ial current, $I_1 = 3{\cdot}2$ A; steady current, $I_2 = 2{\cdot}8$ A

erefore, resistance of wire at room temperature (θ_1),

$$R_1 = \frac{V}{I_1} = \frac{230}{3\cdot2} = 71{\cdot}875\ \Omega$$

Resistance of wire at steady temperature (θ_2),

$$R_2 = \frac{V}{I_2} = \frac{230}{2\cdot8} = 82{\cdot}143\ \Omega$$

Temperature coefficient of the wire, $\alpha = 1{\cdot}70 \times 10^{-4}\ °C^{-1}$

Now, $$\alpha = \frac{R_2 - R_1}{R_1(\theta_2 - \theta_1)}$$

$$\therefore\ 1{\cdot}70\times10^{-4} = \frac{82\cdot143 - 71\cdot875}{71\cdot875\times(\theta_2 - 27)}$$

or $$\theta_2 = 27 + \frac{82\cdot143 - 71\cdot875}{71\cdot875\times1\cdot70\times10^{-4}}$$

$= 27 + 840{\cdot}35 = \mathbf{867{\cdot}35\ °C}$

Type I. On colour code of carbon resistance

Problem 1.19. A carbon resistor has coloured strips as shown in Fig. 1.20. What is its resistance ?

(H.S.S.C.E. 1996 ; H.P.S.S.C.E. 1995 ; C.B.S.E. 1990)

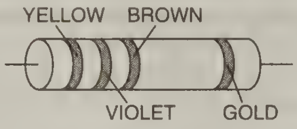

Fig. 1.20

Sol. Corresponding to first two colour bands of yellow and violet colours, the figures are 4 and 7. Corresponding to the third band of brown colour, the multiplier is 10^1 *i.e.* 10. Therefore, the given carbon resistor is of value 47 × 10 *i.e.* 470 Ω. Since the band showing the tolerance is golden, the value of resistor,

$$R = \mathbf{470\ \Omega \pm 5\%}$$

Problem 1.20. How will you represent a resistance of 3700 Ω ± 10% by colour code ? *(H.S.S.C.E. 2001)*

Sol. Here, $R = 3700\ \Omega \pm 10\% = 37 \times 10^2\ \Omega \pm 10\%$

According to colour code of carbon resistance, the colour of bands corresponding to figures 3 and 7 are orange and violet respectively and corresponding to multiplier 10^2, the colour of band is red. Finally, corresponding to tolerance of 10%, the colour of band is silver.

Therefore, the resistance of 3700 Ω ± 10% will be represented by the bands of colour **orange, violet, red and silver.**

Type J. On series and parallel combination of resistances

Problem 1.21. (*a*) **Three resistors, 1 Ω, 2 Ω and 3 Ω are combined in series. What is the total resistance of the combination ?**

(*b*) **If the combination is connected to a battery of e.m.f. 12 V and negligible internal resistance, obtain the potential drop across each resistor.** *(Text Problem)*

Sol.(*a*) Here, $R_1 = 1\ \Omega$; $R_2 = 2\ \Omega$; $R_3 = 3\ \Omega$

Now, $R_s = R_1 + R_2 + R_3 = 1 + 2 + 3 = 6\ \Omega$

(*b*) Here, $E = 12\ V$; $r = 0$

Therefore, current in the circuit, $I = \frac{E}{R_s} = \frac{12}{6} = 2\ A$

P.D. across $R_1 = I\,R_1 = 2 \times 1 = \mathbf{2\ V}$;

P.D. across $R_2 = I\,R_2 = 2 \times 2 = \mathbf{4\ V}$;

P.D. across $R_3 = I\,R_3 = 2 \times 3 = \mathbf{6\ V}$

Problem 1.22. (*a*) **Three resistors 2 Ω, 4 Ω and 5 Ω are combined in parallel. What is the total resistance of the combination ?**

(b) If the combination is connected to a battery of e.m.f. 20 V and negligible internal resistance, determine the current through each resistor and the total current drawn from the battery. (*Text Problem*)

Sol. (*a*) Here, $R_1 = 2\,\Omega$; $R_2 = 4\,\Omega$; $R_3 = 5\,\Omega$

The resistance of the parallel combination of the resistors given by

$$\frac{1}{R_p} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} = \frac{1}{2} + \frac{1}{4} + \frac{1}{5}$$

$$= \frac{10+5+4}{20} = \frac{19}{20}$$

or $\quad R_p = \frac{20}{19}\,\Omega$

(*b*) Here, $\quad E = 20\text{ V}$; $r = 0$

The current drawn from the battery,

$$I = \frac{E}{R_p} = \frac{20}{20/19} = \mathbf{19\ A}$$

Let I_1, I_2 and I_3 be current through resistors R_1, R_2 and R_3 respectively.

Then, $\quad I_1 = \frac{E}{R_1} = \frac{20}{2} = \mathbf{10\ A}$; $I_2 = \frac{E}{R_2} = \frac{20}{4} = \mathbf{5\ A}$;

$$I_3 = \frac{E}{R_3} = \frac{20}{5} = \mathbf{4\ A}$$

Problem 1.23. The resistance of two conductors in series is 40 ohm and their resistance becomes 7·5 ohm, when connected in parallel. Find the resistance of individual conductors.

Sol. Let the resistance of the two conductors be R_1 and R_2.

Then, $\quad R_s = R_1 + R_2 = 40\,\Omega \quad$ ...(*i*)

and $\quad R_p = \frac{R_1 R_2}{R_1 + R_2} = 7{\cdot}5\,\Omega \quad$ ...(*ii*)

From equation (*ii*), we have

$$R_1 R_2 = 7{\cdot}5 \times (R_1 + R_2)$$

Using equation (*i*), we have

$$R_1 R_2 = 7{\cdot}5 \times 40 = 300$$

Now, $(R_1 - R_2)^2 = (R_1 + R_2)^2 - 4 R_1 R_2 = 40^2 - 4 \times 300 = 400$

$\therefore \quad R_1 - R_2 = 20\,\Omega \quad$ ...(*iii*)

Adding equations, (*i*) and (*iii*), we have

$$2 R_1 = 40 + 20 = 60 \quad \text{or} \quad \mathbf{R_1 = 30\,\Omega}$$

Subtracting equation (*iii*) from (*i*), we have

$$2 R_2 = 40 - 20 = 20 \quad \text{or} \quad \mathbf{R_2 = 10\,\Omega}$$

Problem 1.24. A resistor of 5 Ω resistance is connected in series with a parallel combination of a number of resistors each of 6 Ω. If the total resistance of the combination is 7 Ω, how many resistors are in parallel ?

Sol. Let *n* resistors each of 6 Ω be connected in parallel and then the combination be connected in series with resistor of 6 Ω. The resistance of the parallel combination of *n* resistors each of 6 Ω is given by

$$\frac{1}{R_p} = \frac{1}{6} + \frac{1}{6} + \frac{1}{6} \ldots\ldots n \text{ times} = \frac{n}{6}$$

or $\quad R_p = \frac{6}{n}\,\Omega$

As this parallel combination is connected in series with the resistor of 5 Ω, the total resistance of the combination is given by

$$R = R_p + 5 = \frac{6}{n} + 5$$

Since resistance of the combination is 7 Ω, it follo

$$\frac{6}{n} + 5 = 7 \quad \text{or} \quad \frac{6}{n} = 2 \quad \text{or} \quad n = 3$$

Problem 1.25. Five resistors are connected as sh Fig. 1.21. Find the equivalent resistance between the B and C. (*P.S.S.C.E*

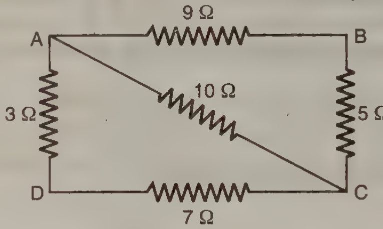

Fig. 1.21

Sol. The resistances of segments AB and BC are in If R_1 is effective resistance of the part ABC of the circu

$$R_1 = 9 + 5 = 14\,\Omega$$

Also, the resistances of segments AD and DC series. If R_2 is effective resistance of the part ADC circuit, then

$$R_2 = 3 + 7 = 10\,\Omega$$

The resistances R_1, 10 Ω (of segment AC) and R parallel. If R is the effective resistance of the circuit,

$$\frac{1}{R} = \frac{1}{14} + \frac{1}{10} + \frac{1}{10} = \frac{5+7+7}{70} = \frac{19}{70}$$

or $\quad R = \frac{70}{19}\,\Omega$

Problem. 1.26. For the combination of resis shown in the Fig. 1.22, find the effective resistance b the points A and B. (*I.I.T*

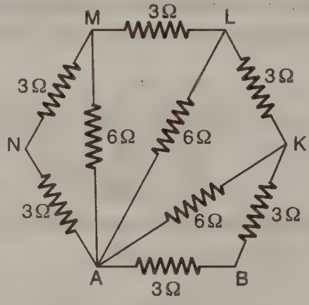

Fig. 1.22

Sol. Consider the part AMNA of the network. Th tances AN (= 3 Ω) and NM (= 3 Ω) are in series and the their effective resistance,

$$R_1 = 3 + 3 = 6\ \Omega$$

The effective resistance R_1 and resistance AM (= in parallel. Therefore, effective resistance of part A given by

$$R_2 = \frac{6 \times 6}{6+6} = 3\,\Omega$$

Now, effective resistance R_2 and resistance ML are in series and this series combination having res 3 + 3 *i.e.* 6 Ω is in parallel to resistance AL (= 6 Ω). If R_3 effective resistance, then

$$R_3 = \frac{6 \times 6}{6+6} = 3\,\Omega$$

Similarly, resistance of part AKLMNA is given by

$$R_4 = \frac{6\times6}{6+6} = 3\ \Omega$$

Finally, the effective resistance R_4 and the resistance KB Ω) are in series and this series combination having stance 3 + 3 *i.e.*6 Ω is connected in paralled across tance AB (= 3 Ω).

Therefore, equivalent resistance of the network is given

$$R = \frac{6\times3}{6+3} = 2\ \Omega$$

Problem 1.27. Three resistances of 30 Ω each are ected to form a triangle. A cell of e.m.f. 2 V and negli- e internal resistance is connected between any two ces [Fig. 1.23]. Find the current through the cell.

(I.I.T. 1983)

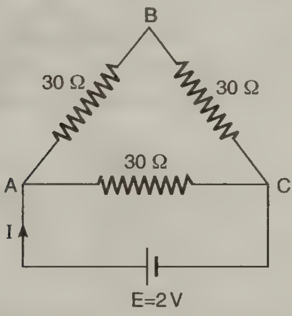

Fig. 1.23

Sol. The resistances AB and BC are in series and their tive resistance,

$$R_1 = 30 + 30 = 60\ \Omega$$

The effective resistance R_1 (= 60 Ω) and the resistance = 30 Ω) are in parallel. The equivalent resistance of the ork is given by

$$R = \frac{60\times30}{60+30} = 20\ \Omega$$

If I is current through the cell, then

$$I = \frac{E}{R} = \frac{2}{20} = \mathbf{0{\cdot}1\ A}$$

Problem 1.28. As shown in Fig. 1.24, a variable rheostat kΩ is used to control the potential difference across a Ω load.

(*a*) If the resistance AB is 500 Ω, what is the potential erence across the load ?

(*b*) If the load is removed, what should be the tance at BC to get 40 V between B and C ?

(I S.C.E. 1996)

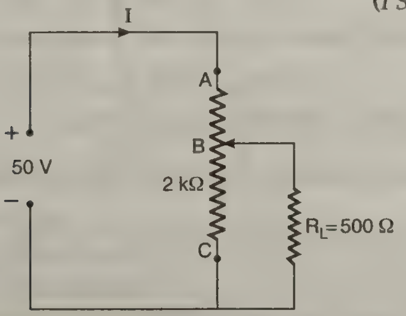

Fig. 1.24

Sol. Here, load resistance, $R_L = 500\ \Omega$;

and e.m.f. of the source, E = 50 V

Total resistance of the rheostat between points A and C,

$$R_{AC} = 2\ k\Omega = 2000\ \Omega$$

Resistance of the rheostat between points A and B,

$$R_{AB} = 500\ \Omega$$

Therefore, resistance between points B and C,

$$R_{BC} = R_{AC} - R_{AB} = 2000 - 500 = 1500\ \ \Omega$$

Now, R_{BC} and R_L are connected in parallel. If R′ is resistance of their combination, then

$$\frac{1}{R'} = \frac{1}{R_{BC}} + \frac{1}{R_L} = \frac{1}{1500} + \frac{1}{500} = \frac{4}{1500}$$

or $R' = 375\ \Omega$

Further, R_{AB} and R′ are in series. If I is current in the circuit, then

$$I = \frac{E}{R_{AB}+R'} = \frac{50}{500+375} = \frac{2}{35}\ A$$

(*a*) It follows that potential drop across R_L is same as the potential drop across the parallel combination of R_{BC} and R_L.

Therefore, potential drop across R_L

= applied potential difference

−potential drop across R_{AB}

$$= 50 - I\,R_{AB} = 50 - \frac{2}{35} \times 500 = \mathbf{21{\cdot}43\ V}$$

(*b*) When the load is removed, the source of e.m.f. will send current through the rheostat wire AB having a total resistance of 2000 Ω. Therefore, current through the rheostat,

$$I' = \frac{50}{2000} = \frac{1}{40}\ A$$

If R_{BC}' is the value of the resistance of the rheostat between points B and C, which will give a potential difference of 40 V across these two points, then

$$I'\,R_{BC}' = 40$$

or $$R_{BC}' = \frac{40}{I'} = \frac{40}{1/40} = \mathbf{1600\ \Omega}$$

Problem 1.29. Four resistors of 12 Ω each are connected in parallel. Three such combinations are then connected in series. What is the total resistance ? If a battery of 9 V e.m.f. and negligible internal resistance is connected across the network of resistors, find the current flowing through each resistor.

(H.S.S.C.E. 2002)

Sol. The network of resistors is connected to the battery of e.m.f. 9 V as shown in Fig. 1.25. Let I be the total current in the circuit. If R′ is effective resistance of the four resistors of 12 Ω each connected in parallel, then

$$\frac{1}{R'} = \frac{1}{12} + \frac{1}{12} + \frac{1}{12} + \frac{1}{12} = \frac{4}{12} \quad \text{or} \quad R' = 3\ \Omega$$

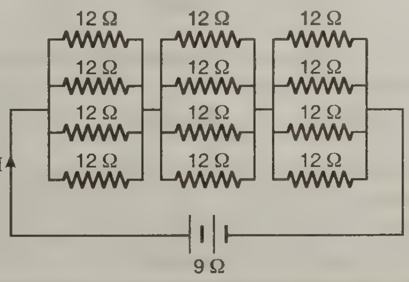

Fig. 1.25

Therefore, effective resistance of the network of resistors,

$$R = R' + R' + R' = 3 + 3 + 3 = \mathbf{9\ \Omega}$$

The current in the circuit,

$$I=\frac{E}{R}=\frac{9}{9}=\mathbf{1\,A}$$

Since all the four resistors are of same resistance, equal current will pass through each resistor. Therefore,

$$\text{current through each resistor}=\frac{1}{4}I=\frac{1}{4}\times 1=\mathbf{0{\cdot}25\ A}$$

Problem. 1.30. Find the current drawn from a cell of e.m.f. 1 V and internal resistance 2/3 Ω connected to the network shown in Fig. 1.26. *(C.B.S.E. 2001 S)*

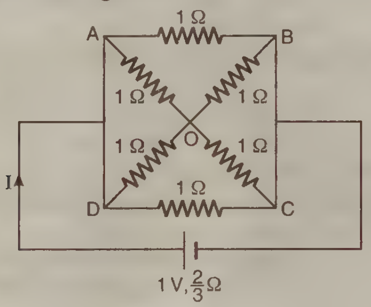

Fig. 1.26

Sol. Here, E = 1 and $r = 2/3\ \Omega$

Let I be the current drawn by the network from the cell. The given network can be respresented as shown in Fig. 1.27.

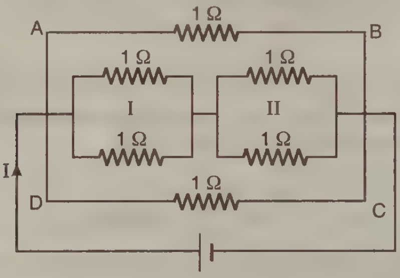

Fig. 1.27

Each of the sub-networks I and II is a parallel combination of two resistances of 1 Ω each. Further, the two sub-networks I and II are in series with each other. If R′ is the effective resistance of I and II, then

$$R'=\frac{1\times 1}{1+1}+\frac{1\times 1}{1+1}=\frac{1}{2}+\frac{1}{2}=1\,\Omega$$

The network shown in Fig. 1.27 is now, equivalent to the arrangement as shown in Fig. 1.28.

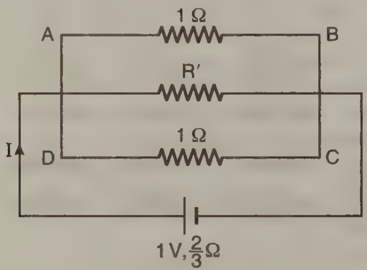

Fig. 1.28

If R is equivalent resistance to the network ABCD, then

$$\frac{1}{R}=\frac{1}{1}+\frac{1}{1}+\frac{1}{1}=\frac{3}{1}\quad\text{or}\quad R=\frac{1}{3}\,\Omega$$

Therefore, current in the circuit,

$$I=\frac{E}{R+r}=\frac{1}{1/3+2/3}=\mathbf{1\,A}$$

Problem 1.31. A letter A is constructed of a unifo wire of resistance 1 Ω cm^{-1}. The sides of the letter are cm long and the cross-piece in the middle is 10 cm lor while the apex angle is 60° [Fig. 1.29]. Find the curr flowing through the different parts, when a battery of e.n 15 V and internal resistance 3·33 Ω is connected across two ends of the legs.

Sol. The letter A is formed of a uniform wire as sho in Fig 1.29.

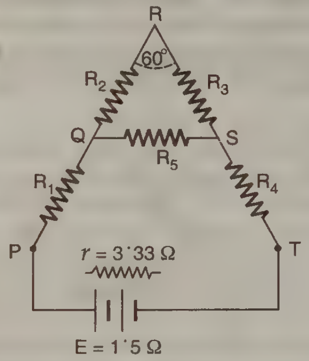

Fig. 1.29

As the apex angle is 60° and the cross-piece QS is in middle of the two legs PR and RT,

$$PQ = QR = RS = ST = QS = 10\text{ cm}$$

Now, the wire has a resistance of 1 Ω cm^{-1}.

$$\therefore\qquad R_1=R_2=R_3=R_4=R_5=10\,\Omega$$

Let R_p be the resistance of the triangular part QRS of letter A. It is series combination of R_2 and R_3 connectec parallel with R_5. Then, It is

$$\frac{1}{R_p}=\frac{1}{R_5}+\frac{1}{R_2+R_3}=\frac{1}{10}+\frac{1}{10+10}=\frac{1}{10}+$$

$$\text{or}\qquad R_p=\frac{20}{3}\,\Omega$$

If R is the resistance of the letter between the two e of the legs *i.e.* P and T, then

$$R=R_1+R_p+R_4=10+\frac{20}{3}+10=\frac{80}{3}$$

$$=\mathbf{26{\cdot}67\ W}$$

Let I be the current flowing through the main circu

$$\text{Then,}\qquad I=\frac{E}{R+r}=\frac{15}{26{\cdot}67+3{\cdot}33}=\frac{15}{30}=0{\cdot}5\,A$$

Potential difference across the triangular part QRS,

$$V=I\times R_p=0{\cdot}5\times\frac{20}{3}=\frac{10}{3}\,V$$

Therefore, current through part QRS

$$=\frac{V}{R_2+R_3}=\frac{10/3}{10+10}=\frac{1}{6}\,A=\mathbf{0{\cdot}167\ A}$$

$$\text{and current through part QS}=\frac{V}{R_5}=\frac{10/3}{10}=\frac{1}{3}\,A$$

$$=\mathbf{0{\cdot}333\ A}$$

The current through parts PQ or ST is same as t flowing through the main circuit *i.e.* **0·5 A.**

Problem 1.32. Calculate the steady state curr through the circuit shown in Fig. 1.30. The internal re

of the battery is negligible and the capacitance of the itor is 0·5 μF. (*H.S.S.C.E. 2001*)

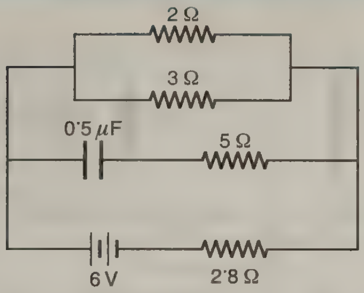

Fig. 1.30

Sol. Let I be the steady state current through the circuit. When steady state is reached *i.e* when the current in the it becomes constant, the capacitor offers infinite ance. As a result, it behaves as an open path and the ance of 5 Ω in the circuit becomes ineffective. Therefore, ven circuit may be represented as shown in Fig. 1.31.

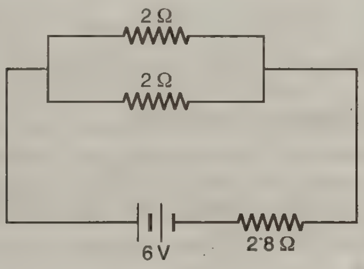

Fig. 1.31

The effective resistance of the circuit,

$$R = \frac{2 \times 3}{2+3} + 2{\cdot}8 = 1{\cdot}2 + 2{\cdot}8 = 4\ \Omega$$

Therefore, current in steady state of the circuit,

$$I = \frac{E}{R} = \frac{6}{4} = 1{\cdot}5\ \text{A}$$

K. On internal resistance of a cell

Problem 1.33. A battery of e.m.f. 10 V and internal tance 3 Ω is connected to a resistor. If the current gh the circuit is 0·5 A, what is the resistance of the or ? What is the terminal voltage of the battery, when rcuit is closed ? (*Text Problem*)

Sol. Here, E = 10 V ; $r = 3\ \Omega$; I = 0·5 A

Let R be the resistance of the resistor. Then,

$$I = \frac{E}{R + r}$$

or $$R = \frac{E}{I} - r - \frac{10}{0{\cdot}5} - 3 = 17\ \Omega$$

Now, terminal voltage of the battery

= potential difference across R

= I R = 0·5 × 17 = **8·5 V**

Note. The terminal voltage of the battery is also given

$$E - I\,r = 10 - 0{\cdot}5 \times 3 = \mathbf{8{\cdot}5\ V}$$

Problem 1.34. A battery of e.m.f. E and internal ance *r* gives a current of 0·5 A with an external resistor ohm and a current of 0·25 A with an external resistor ohm. Calculate (*a*) internal resistance of the cell and m.f. of the cell. (*C.B.S.E. 2002*)

Sol. When an external resistance R is connected to a battery of e.m.f. E and internal resistance *r*, current in the circuit,

$$I = \frac{E}{R + r}$$

In first case : Here, R = 12 Ω ; I = 0·5 A

$$\therefore \qquad 0{\cdot}5 = \frac{E}{(12 + r)}$$

or $$E = (12 + r) \times 0{\cdot}5 \qquad \text{...(}i\text{)}$$

In second case : Here, R = 25 Ω ; I = 0·25 A

$$\therefore \qquad 0{\cdot}25 = \frac{E}{(25 + r)}$$

or $$E = (25 + r) \times 0{\cdot}25 \qquad \text{...(}ii\text{)}$$

From equation (*i*) and (*ii*), we have

$$(12 + r) \times 0{\cdot}5 = (25 + r) \times 0{\cdot}25$$

or $$r = \mathbf{1\ \Omega}$$

Substituting for *r* in equation (*i*), we have

$$E = (12 + 1) \times 0{\cdot}5 = \mathbf{6{\cdot}5\ V}$$

Problem 1.35. Three resistors of 3 Ω, 4 Ω and 6 Ω are connected in parallel. The combination is connected to a cell of e.m.f. 2 V and internal resistance 2/3 Ω. Find the current drawn from the cell and the current through 3 Ω resistance. (*Karnataka, 1989*)

Sol. The resistors of 3 Ω, 4 Ω and 6 Ω are connected in parallel to the cell of e.m.f. 2 V as shown in Fig. 1.32.

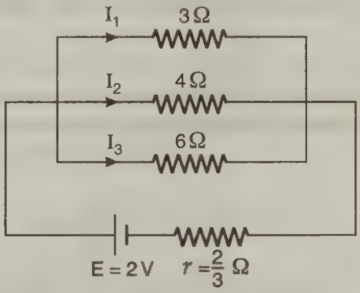

Fig. 1.32

Let R_p be the effective resistance of the parallel combination of 3 Ω, 4 Ω and 6 Ω resistances. Then,

$$\frac{1}{R_p} = \frac{1}{3} + \frac{1}{4} + \frac{1}{6} = \frac{9}{12} \quad \text{or} \quad R_p = \frac{12}{9} = \frac{4}{3}$$

Total resistance of the circuit,

$$R = R_p + r = \frac{4}{3} + \frac{2}{3} = 2\ \Omega$$

Therefore, current is the circuit, $I = \frac{E}{R} = \frac{2}{2} = \mathbf{1\ A}$

Now, potential difference across the parallel combination

$$= I \times R_p = 1 \times \frac{4}{3} = \frac{4}{3}\ \text{V}$$

As potential difference across each of the three resistances is 4/3 V, the current through 3 Ω resistance,

$$I = \frac{4/3}{3} = \frac{4}{9}\ \mathbf{A}$$

Problem 1.36. A uniform wire of resistance 12 Ω is cut into three pieces in the ratio 1 : 2 : 3 and the three pieces are connected to form a triangle. A cell of e.m.f. 8 V and internal resistance 1 Ω is connected across the highest of the three resistors. Calculate the current through each part of the circuit. (*Karnataka, 1994*)

Sol. Suppose that the 12 Ω wire is cut into three pieces AB, BC and AC in the ratio 1 : 2 : 3. Then, resistances of parts

AB, BC and AC are 2 Ω, 4 Ω, and 6 Ω respectively. The cell of e.m.f. 8 V and internal resistance 1 Ω is connected across AC (highest resistor) as shown in Fig. 1.33.

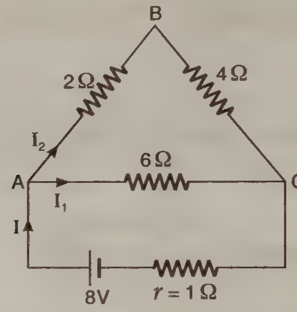

Fig. 1.33

Since the series combination of resistors AB and BC is in parallel with AC, it can be obtained that the resistance of the triangular part ABC of the network is 3 Ω. Therefore,

$$\text{current from the battery, } I = \frac{E}{R+r} = \frac{8}{3+1} = 2\text{ A}$$

Suppose that a part I_1 of the total current I flows along path AC and remaining part I_2 flows along path ABC. Since resistances of the paths AC and ABC are equal,

$$I_1 = I_2 = I/2 = \mathbf{1\ A}$$

Problem 1.37. In the circuit given in Fig. 1.34, a potential difference of 3 V is required across the points A and B. Calculate the value of the resistance R_1.

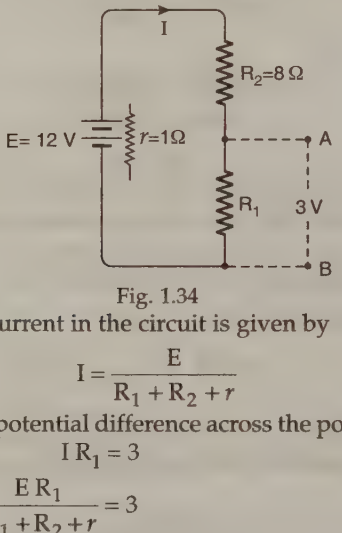

Fig. 1.34

Sol. The current in the circuit is given by

$$I = \frac{E}{R_1 + R_2 + r}$$

Required potential difference across the points A and B,

$$I R_1 = 3$$

$$\therefore \quad \frac{E R_1}{R_1 + R_2 + r} = 3$$

Here, $E = 12\text{ V}$; $R_2 = 8\ \Omega$ and $r = 1\ \Omega$

$$\therefore \quad \frac{12 R_1}{R_1 + 8 + 1} = 3 \quad \text{or} \quad 4 R_1 = R_1 + 9$$

$$\text{or} \quad \mathbf{R_1 = 3\ \Omega}$$

Problem 1.38. A 20 V battery of internal resistance 1 Ω is connected to three coils of 12 Ω, 6 Ω and 4 Ω in parallel, a resistor of 5 Ω and a reversed battery (e.m.f. 8 V and internal resistance 2 Ω) as shown in Fig. 1.35. Calculate (*a*) the current in the circuit, (*b*) current in resistor of 12 Ω coil and (*c*) potential difference acorss each battery. (*C.B.S.E .2001 S*)

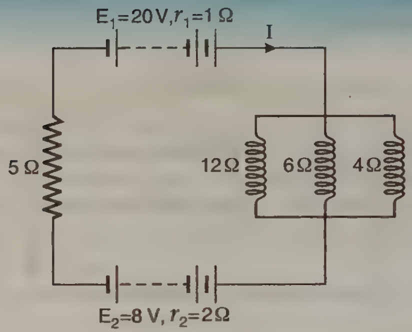

Fig. 1.35

Sol. Here, $E_1 = 20\text{ V}$; $r_1 = 1\ \Omega$; $E_2 = 8\text{ V}$ and $r_2 = 2$

(*a*) Let I be current in the circuit.

Total e.m.f of the circuit,

$$E = E_1 - E_2 = 20 - 8 = 12\text{ V}$$

Let R′ be the resistance of parallel combiantion o coils of resistances 12 Ω, 6 Ω and 4 Ω. Then,

$$\frac{1}{R'} = \frac{1}{12} + \frac{1}{6} + \frac{1}{4} = \frac{1}{2} \quad \text{or} \quad R' = 2\ \Omega$$

Therefore, total resistance of the circuit,

$$R = R' + r_1 + r_2 + 5 = 2 + 1 + 2 + 5 = 10$$

Hence, current in the circuit,

$$I = \frac{E}{R} = \frac{12}{10} = \mathbf{1{\cdot}2\ A}$$

(*b*) Let current through 12 Ω, 6 Ω and 4 Ω resista be I_1, I_2 and I_3 respectively.

Then, $I_1 + I_2 + I_3 = 1{\cdot}2$

Also $\quad I_1 \times 12 = I_2 \times 6 = I_3 \times 4$

From equation (*ii*), we have

$$I_2 = 2 I_1 \quad \text{and} \quad I_3 = 3 I_1$$

Therefore, equation (*i*) becomes

$$I_1 + 2 I_1 + 3 I_1 = 1{\cdot}2 \quad \text{or} \quad I_1 = \mathbf{0{\cdot}2\ A}$$

(*c*) The terminal potential difference across 12 V bat

$$V_1 = E_1 - I r_1 = 20 - 1{\cdot}2 \times 1 = \mathbf{18{\cdot}8\ V}$$

Since potential drop across internal resistance of battery aids its e.m.f., the terminal potential difference ac 8 V battery,

$$V_2 = E_2 + I r_2 = 8 + 1{\cdot}2 \times 2 = \mathbf{10{\cdot}4\ V}$$

Type L. On Grouping of cells

Problem 1.39. Six lead-acid type of secondary c each of e.m.f. 2·0 V and internal resistance 0·015 Ω are joi in series to provide a supply to a resistance of 8·5 Ω. W is the current drawn from the supply and its termi voltage ? (*Text Prob*

Sol. When cells are connected in series, the total e. is equal to sum of their e.m.fs.

Therefore, total e.m.f. of the cells, $E = 2{\cdot}0 \times 6 = 12{\cdot}$

Also, total internal resistance, $r = 0{\cdot}015 \times 6 = 0{\cdot}09$

External resistance, $R = 8{\cdot}5\ \Omega$

Therefore, current drawn from the supply,

$$I = \frac{E}{R+r} = \frac{12{\cdot}0}{8{\cdot}5 + 0{\cdot}09} = \mathbf{1{\cdot}397\ A}$$

Terminal voltage, $V = I R = 1{\cdot}397 \times 8{\cdot}5 = \mathbf{11{\cdot}857\ V}$

Problem 1.40. Three identical cells each of e.m.f. and internal resistance *r* are connected in series to a resistor. If the current flowing in the circuit is 1· calculate (*a*) internal resistance of each cell and (*b*) terminal voltage across the cells. (*C.B.S.E. 2*

Sol. The three cells are connected in series to the external tance of 6 Ω as shown in Fig. 1.36.

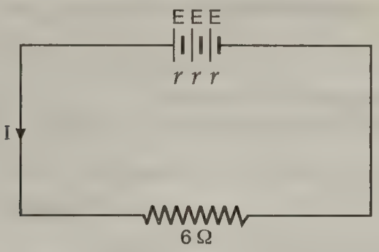

Fig. 1.36

(*a*) Here E = 4 V ; I = 1·5 A and R = 6 Ω

The total e.m.f. in the circuit, $E' = 3E = 3 \times 4 = 12$ V

Total resistance of the circuit, $R' = R + 3r = 6 + 3r$

Therefore, current in the circuit,

$$I = \frac{E'}{R'} \quad \text{or} \quad 1{\cdot}5 = \frac{12}{6+3r}$$

or $\quad r = \frac{2}{3}\,\Omega$

(*b*) Terminal voltage across each cell,

$$V = E - Ir = 4 - 1{\cdot}5 \times \frac{2}{3} = 3\text{ V}$$

Problem 1.41. Four identical cells, each of e.m.f. 2 V, are ed in parallel providing supply of current to external it consisting of two 15 Ω resistors joined in parallel. terminal voltage of the cells as read by an ideal neter is 1·6 V. Calculate the internal resistance of each (*C.B.S.E. 2002*)

Sol. Four cells are connected in parallel to the parallel bination of two 15 Ω resistors as shown in Fig. 1.37.

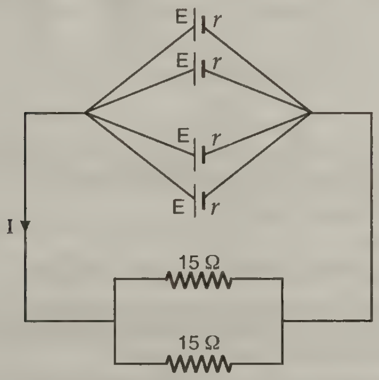

Fig. 1.37

Let *r* be internal resistance of each cell and I be the ent in the circuit. Since the cells are connected in parallel, total e.m.f. in the circuit = e.m.f. of one cell = 2 V

Further, total internal resistance of the cells is given by

$$\frac{1}{r'} = \frac{1}{r} + \frac{1}{r} + \frac{1}{r} + \frac{1}{r} = \frac{4}{r} \quad \text{or} \quad r' = r/4$$

Let R be resistance of the parallel combination of two resistors. Then, total external resistance,

$$R = \frac{15 \times 15}{15 + 15} = 7{\cdot}5\ \Omega$$

Now, internal resistance of the parallel combination of is given by

$$r' = \left(\frac{E}{V} - 1\right)R \quad \text{or} \quad \frac{r}{4} = \left(\frac{2}{1{\cdot}6} - 1\right) \times 7{\cdot}5$$

or $\quad r = 7{\cdot}5\ \Omega$

Problem 1.42. Two identical cells, whether joined together in series or in parallel give the same current, when connected to an external resistance of 1 Ω. Find the internal resistance of each cell. (*I.S.C.E. 1995*)

Sol. Let each cell be of e.m.f. E and internal resistance *r*.

When the two cells are connected in series : Fig. 1.38 shows the series combination of the two cells connected to an external resistance R = 1 Ω.

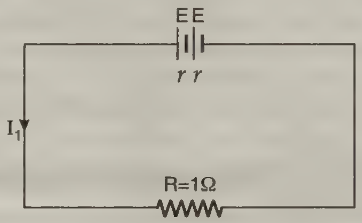

Fig. 1.38

Total resistance of the circuit, $R_1 = R + r + r$

or $\quad R_1 = 1 + 2r$

Total e.m.f. in the circuit, $E_1 = E + E = 2E$

If I_1 is current in the circuit, then

$$I_1 = \frac{E_1}{R_1} = \frac{2E}{1+2r} \qquad ...(i)$$

When the two cells are connected in parallel : Fig. 1.39 shows the parallel combination of the two cells connected to an external resistance R = 1 Ω.

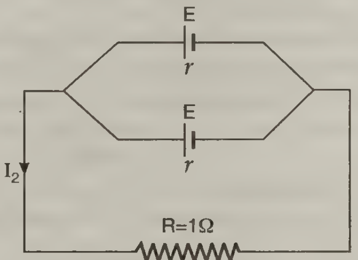

Fig. 1.39

Total internal resistance of two cells = $r/2$

Total resistance of the circuit, $R_2 = R + r/2$

or $\quad R_2 = 1 + r/2$

Total e.m.f. in the circuit = e.m.f. of a single cell = E

If I_2 is current in the circuit, then

$$I_2 = \frac{E_2}{R_2} = \frac{E}{1 + r/2} \qquad ...(ii)$$

Since the two cells give the same current in two cases, we have

$$I_1 = I_2$$

or $\quad \frac{2E}{1+2r} = \frac{E}{1+r/2} \quad$ or $\quad 1 + 2r = 2(1 + r/2)$

or $\quad r = 1\ \Omega$

Problem 1.43. A set of 4 cells, each of e.m.f. 2 V and internal resistance 1·2 Ω, are connected across an external load of 10 Ω with 2 rows, 2 cells in each branch. Calculate the current in each branch and potential difference across 10 Ω. (*Karnataka, 1991 S*)

Sol. The four cells, each of e.m.f. E and internal resistance are connected to the external resistance R as shown in Fig. 1.40.

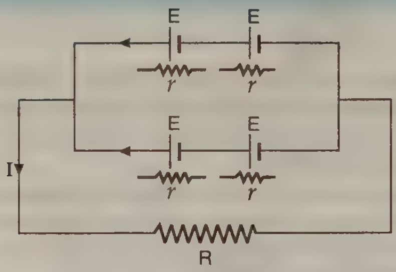

Fig. 1.40

Here, $E = 2\text{ V}$; $r = 1{\cdot}5\ \Omega$ and $R = 10\ \Omega$

The net e.m.f. of the two cells in a row

$$= 2\text{E} = 2 \times 2 = 4\text{ V}$$

The total e.m.f. E′ of the 4 cells is equal to that of a row *i.e.*

$$\text{E}' = 4\text{ V}$$

The internal resistance of the two cells in a row

$$= 1{\cdot}5 + 1{\cdot}5 = 3\ \Omega$$

If r' is internal resistance of the 4 cells, then

$$\frac{1}{r'} = \frac{1}{3} + \frac{1}{3} = \frac{2}{3} \quad \text{or} \quad r' = \frac{3}{2} = 1{\cdot}5\ \Omega$$

Total resistance of the circuit,

$$\text{R}' = \text{R} + r' = 10 + 1{\cdot}5 = 11{\cdot}5\ \Omega$$

Therefore, current in the circuit, $\text{I} = \dfrac{\text{E}'}{\text{R}'} = \dfrac{4}{11{\cdot}5}$

$$= 0{\cdot}348\text{ A}$$

As the two branches are identical,

current in each branch $= \dfrac{\text{I}}{2} = \dfrac{0{\cdot}348}{2}$ = **0·174 A**

Potential difference across external resistance

$$= \text{I R} = 0{\cdot}348 \times 10 = \mathbf{3{\cdot}48\ V}$$

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 1.44. In a discharge tube, the number of hydrogen ions (*i.e.* protons) drifting across a section er second is 1·0 × 10^{18}, while the number of electrons rifting in the opposite direction across another cross-ection is 2·7 × 10^{18} per second. If the supply voltage is 230 , what is the effective resistance of the tube ?

(*P.S.S.C.E. 1995 ; Text Problem*)

Sol. Here, number of electrons moving per second,

$$n_e = 2{\cdot}7 \times 10^{18}$$

and number of protons moving per second,

$$n_p = 1{\cdot}0 \times 10^{18}$$

Since electrons and protons move in opposite directions, otal charge crossing per second *i.e.*

current in the discharge tube, $\text{I} = (n_e + n_p)\, e$

$$= (2{\cdot}7 \times 10^{18} + 1{\cdot}0 \times 10^{18}) \times 1{\cdot}6 \times 10^{-19}$$

$$= 3{\cdot}7 \times 1{\cdot}6 \times 10^{-1} = 0{\cdot}592\text{ A}$$

Now, $\quad$ V = 230 volt

Therefore, effective resistance of the discharge tube,

$$\text{R} = \frac{\text{V}}{\text{I}} = \frac{230}{0{\cdot}592} = \mathbf{388{\cdot}5\ \Omega}$$

Problem 1.45. Two wires of equal length, one of aluminium and the other of copper have the same resisance. Which of the two wires is lighter ? Hence, explain vhy aluminium wires are preferred for overhead power ables. Given that $\rho_{al} = 2{\cdot}63 \times 10^{-8}\ \Omega$ m, $\rho_{cu} = 1{\cdot}72 \times 10^{-8}\ \Omega$ m, elative density of Al = 2·7 and of Cu = 8·9.

(*Text Problem*)

Sol. Let A_1 and A_2 be area of cross-sections of the wires nade from aluminium and copper respectively. Let R_1 and $_2$ be resistances of the same length l of the wires made of luminium and copper respectively.

For aluminium wire :

Density* of aluminium, $d_1 = 2{\cdot}7 \times 10^3\text{ kg m}^{-3}$

and resistivity of aluminium, $\rho_{al} = 2{\cdot}63 \times 10^{-8}\ \Omega\text{ m}$

Then, $\text{R}_1 = \rho_{al}\dfrac{l}{\text{A}_1} = \dfrac{2{\cdot}63 \times 10^{-8} \times l}{\text{A}_1}$

Mass of the aluminium wire, $m_1 = \text{A}_1\, l\, d_1$

or $\quad m_1 = \text{A}_1\, l \times 2{\cdot}7 \times 10^3$

For copper wire :

Density of copper, $d_2 = 8{\cdot}9 \times 10^3\text{ kg m}^{-3}$

and resistivity of copper, $\rho_{cu} = 1{\cdot}72 \times 10^{-8}\ \Omega\text{ m}$

Then, $\text{R}_2 = \rho_{cu}\dfrac{l}{\text{A}_2} = \dfrac{1{\cdot}72 \times 10^{-8} \times l}{\text{A}_2}$

Mass of the copper wire, $m_2 = \text{A}_2\, l\, d_2$

or $\quad m_2 = \text{A}_2\, l \times 8{\cdot}9 \times 10^3$

$$\therefore \quad \frac{m_2}{m_1} = \frac{\text{A}_2\, l \times 8{\cdot}9 \times 10^3}{\text{A}_1\, l \times 2{\cdot}7 \times 10^3} = \frac{8{\cdot}9}{2{\cdot}7} \times \frac{\text{A}_2}{\text{A}_1} \qquad \text{...(}i\text{)}$$

Since two wires are of equal resistances, we have

$$\frac{2{\cdot}63 \times 10^{-8} \times l}{\text{A}_1} = \frac{1{\cdot}72 \times 10^{-8} \times l}{\text{A}_2}$$

$$\text{or} \quad \frac{\text{A}_2}{\text{A}_1} = \frac{1{\cdot}72}{2{\cdot}63} \qquad \text{...(}ii\text{)}$$

From equations (*i*) and (*ii*), we have

$$\frac{m_2}{m_1} = \frac{8{\cdot}9}{2{\cdot}7} \times \frac{1{\cdot}72}{2{\cdot}63} = 2{\cdot}16 \quad \text{or} \quad m_1 = \frac{m_2}{2{\cdot}16}$$

It follows that **aluminium wire** is lighter.

Since for the same value of resistance and length, aluminium wire has lesser mass, aluminium wires are preferred for overhead power cables.

Problem 1.46. It is desired to make a coil of resistance 20 Ω having a zero temperature coefficient of resistance. To achieve this, a carbon resistor of resistance R_1 is placed in series with an iron resistor of resistance R_2. The proportion of carbon and iron resistances are so chosen that $\text{R}_1 + \text{R}_2 = 20\ \Omega$ for all temperatures near the room temperature. If the temperature coefficient of resistance for carbon and iron are $\alpha_1 = -0{\cdot}5 \times 10^{-3}\ {}^\circ\text{C}^{-1}$ and $\alpha_2 = 5 \times 10^{-3}\ {}^\circ\text{C}^{-1}$ respectively, calculate the values of R_1 and R_2.

Sol. Here, $\text{R}_1 + \text{R}_2 = 20\ \Omega$;

$$\alpha_1 = -0{\cdot}5 \times 10^{-3}\ {}^\circ\text{C}^{-1}\ ; \alpha_2 = 5 \times 10^{-3}\ {}^\circ\text{C}^{-1}$$

Let θ be a small rise in temperature near the room temperature.

Then, new resistance of the carbon and iron resistances will be

$$\text{R}_1' = \text{R}_1(1 + \alpha_1\theta) \quad \text{and} \quad \text{R}_2' = \text{R}_2(1 + \alpha_2\theta)$$

---

*If relative density of aluminium is 2·7, its density in SI will e 2·7 × 10^3 kg m^{-3}.

Since the resistance coil formed should have zero emperature coefficient,

$$R_1' + R_2' = R_1 + R_2$$

or $R_1(1+\alpha_1\theta) + R_2(1+\alpha_2\theta) = R_1 + R_2$

or $$R_1\alpha\,\theta + R_2\,\alpha_2\,\theta = 0$$

or $R_1 = -\dfrac{\alpha_2}{\alpha_1}R_2 = -\dfrac{5\times10^{-3}}{-0.5\times10^{-3}}R_2 = 10\,R_2$

Now, $R_1 + R_2 = 20$

$\therefore$ $10\,R_2 + R_2 = 20$ or $R_2 = \mathbf{1.82\ \Omega}$

Also, $R_1 = 20 - R_2 = 20 - 1.82 = \mathbf{18.18\ \Omega}$

Problem 1.47. Determine the current drawn from a 12 V supply with internal resistance 0·5 Ω by the infinite etwork shown in Fig. 1.41. Each resistor has 1 Ω resistance.

(H.S.S.C.E. 2002 ;Text Problem)

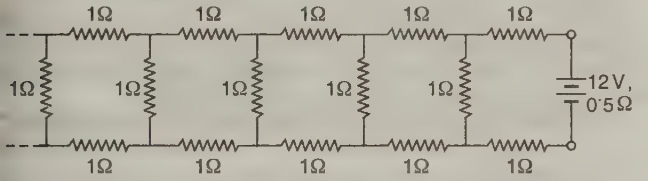

Fig. 1.41

Sol. Let the resistance equivalent to the entire network e X. Since the network is infinite, adding one more set of hree resistances each of value R = 1 Ω across the terminals vill not affect the total resistance *i.e.* it should still remain qual to X. Therefore, the network on adding one set of three esistances would appear as shown in Fig. 1.42.

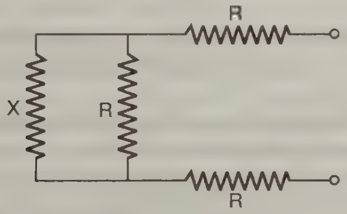

Fig. 1.42

If R′ is equivalent resistance of this new network, then

R′ = R + (resistance equivalent to parallel combination of X and R) + R

$$= R + \frac{XR}{X+R} + R = 2R + \frac{XR}{X+R}$$

As said above, the addition of one set of such three esistances should not alter the total resistance of the infinite etwork. Therefore,

$$R' = X \quad \text{or} \quad 2R + \frac{XR}{X+R} = X$$

Since R = 1 Ω, we have

$$2\times1 + \frac{X\times1}{X+1} = X \quad \text{or} \quad 2 + \frac{X}{X+1} = X$$

or $X^2 - 2X - 2 = 0$

or $$X = \frac{-(-2)\pm\sqrt{(-2)^2 - 4\times1\times(-2)}}{2}$$

or $$X = 1 \pm \sqrt{3}$$

Since the value of resistance cannot be negative, we have

$$X = 1+\sqrt{3} = 2.732\ \Omega$$

Now, $E = 12\text{ V}\,;\, r = 0.5\ \Omega$

If I is current drawn by the network, then

$$I = \frac{E}{X+r} = \frac{12}{2.732+0.5} = \mathbf{3.713\ A}$$

Problem 1.48. A battery of e.m.f. 24 V is used to supply current through the combination of three resistors R_1, R_2 and R_3 as shown in Fig. 1.43. When the key K is closed, the current through 5 Ω resistor is found to be I = 3 A.

(*a*) Find the internal resistance (*r*) of the cell and the currents I_1 and I_2 through the resistors R_1 and R_2. (*b*) What current will flow in the circuit, if the key is opened ?

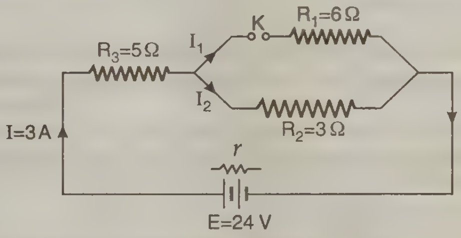

Fig. 1.43

Sol. (*a*) ***On closing the key*** : Let R_p be the resistance of the parallel combination of R_1 and R_2.

Then, $$R_p = \frac{R_1R_2}{R_1+R_2} = \frac{6\times3}{6+3} = 2\ \Omega$$

If *r* is internal resistance of the battery, then total resistance of the circuit,

$$R = R_3 + R_p + r$$

or $$R = 5 + 2 + r = 7 + r$$

Therefore, current in the main circuit,

$$I = \frac{E}{R}$$

Here, E = 24 V and I = 3 A

$\therefore$ $3 = \dfrac{24}{7+r}$ or $7 + r = 8$

or $r = 1\ \Omega$

Now, potential difference across parallel combination of R_1 and R_2,

$$V = I\times R_p = 3\times2 = 6\text{ volt}$$

$\therefore$ $I_1 = \dfrac{V}{R_1} = \dfrac{6}{6} = 1\text{ A}$ and $I_2 = \dfrac{V}{R_2} = \dfrac{6}{3} = 2\text{ A}$

(*b*) ***On opening the key*** : Total resistance of circuit,

$$R' = R_2 + R_3 + r = 3 + 5 + 1 = 9\ \Omega$$

Therefore, current in the circuit, $I' = \dfrac{E}{R'} = \dfrac{24}{9} = \dfrac{8}{3}$ **A**

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 1.01. What is the number of electrons that consti-utes a current of one ampere ? *(H.S.S.C.E. 2001)*

Ans. Number of electrons constituting a current of A,

$$n = \frac{I}{e} = \frac{1\,\text{C s}^{-1}}{1.6\times10^{-19}\ \text{C}}$$

$$= \mathbf{6.25\times10^{18}\ s^{-1}}$$

Q. 1.02. It is found that 10^{20} electrons, each having a charge of $1{\cdot}6 \times 10^{-19}$ C, pass from a point X towards another point Y in 0·1 s. What is the current and its direction ?

Ans. Here, $q = n\,e = 10^{20} \times 1{\cdot}6 \times 10^{-19} = 16\text{ C}\,;\, t = 0{\cdot}1\text{ s}$

$$\therefore \qquad I = \frac{q}{t} = \frac{16}{0{\cdot}1} = \mathbf{160\ A}$$

The direction of conventional current is **from point Y to X.**

Q. 1.03. What is conventional current ?

Ans. The current that flows from positive pole to negative pole of a cell in the external circuit is called conventional current.

Q. 1.04. Define the unit of current. (*P.S.S.C.E. 1999, 1997 S*)

Ans. *The current through a conductor is called one ampere, if one coulomb of charge flows through the conductor in one second.*

Q. 1.05. Write down the relation between a coulomb and an ampere. (*I.S.C.E. 1996*)

Ans. $1\text{ ampere} = \dfrac{1\text{ coloumb}}{1\text{ second}}$

Q. 1.06. How does the drift velocity of electrons in a metallic conductor vary with increase in temperature ? (*C.B.S.E. 2002*)

Ans. The drift velocity of electrons in a metallic conductor decreases with increase in temperature of the conductor.

For details, refer to note of section 1.10.

Q. 1.07 A steady current flows in a metallic conductor of non-uniform cross-section. Explain which of these quantities is constant along the conductor : current, current density, electric field and drift speed ? (*H.S.S.C.E 2001*)

Ans. Except current, the value of all the quantities depends upon the area of cross-section of the conductor. Hence, only current remains constant, when it flows through a conductor of uniform area of cross-section.

Q. 1.08. The potential difference across a given copper wire is increased. What happens to the drift velocity of the charge carriers ? (*C.B.S.E. 1999 S*)

Ans. We know, $v_d = \dfrac{e\,E}{m}\,\tau$

If l is length of the copper wire and V the potential difference across it, then

$$v_d = \frac{e}{m}\left(\frac{V}{l}\right)\tau = \frac{e\,V}{m\,l}\,\tau$$

Thus, $v_d \propto V$ *i.e.* if potential difference is increased, drift velocity of the electrons will ***increase***.

Q. 1.09. When electrons drift in a metal from lower to higher potential, does it mean that all the free electrons of the metals are moving in the same direction ? (*Text Question*)

Ans. It is not so. The drift velocity is superposed over the random thermal velocities of the electrons.

Q. 1.10. If the electron drift velocity is so small and the charge on electron is small, how can we still obtain large amount of current ? (*Text Question*)

Ans. It is because, number of electrons per unit volume is very large ($\approx 10^{28}\ \text{m}^{-3}$).

Q. 1.11. State Ohm's law. (*H.S.S.C.E. 1996 ; I.S.C.E. 1995 ; C.B.S.E. 1990*)

Ans. For statement of Ohm's law, refer to section 1.06.

Q. 1.12. Does the value of resistance of a conductor depend upon the potential difference applied across it or the current passed through it ?

Ans. No, the resistance of a conductor does not deper upon the potential difference applied across it or the curre passed through it.

Q. 1.13. What is non-ohmic device ? State one examp of it. (*P.S.S.C.E. 200*

Ans. A device, which does not obey ohm's law is calle a non-ohmic device. The resistance offered by a sem conductor diode is an example of non-ohmic device.

Q. 1.14. Define resistivity of the material of a wir State its SI units. (*H.S.S.C.E. 1996, 1995 ; I.S.C.E. 199*

Ans. For definition of resistivity and its SI unit, refer section 1.09.

Q. 1.15. Resistivities of copper, silver and mangani are $1{\cdot}7 \times 10^{-8}\ \Omega$ m, $1{\cdot}0 \times 10^{-8}\ \Omega$ m and $44 \times 10^{-8}\ \Omega$ respectively. Which of these is the best conductor ? (*C.B.S.E. 1999*

Ans. For given length and area of cross-section, tl resistance of a material is directly proportional to its specif resistance. Since the specific resistance is least for silver, it the best conductor of the three given materials.

Q. 1.16. What is the order of resistivity of an insulato (*P.S.S.C.E. 1997*

Ans. The resistivity of an insulator, such as glass or ha rubber is of the order 10^{10}–$10^{14}\ \Omega$ m.

Q. 1.17. If a wire is stretched to double its origin length without loss of mass, how will the resistivity of tl wire be influenced ? (*C.B.S.E. 199*

Or

A wire of resistivity ρ is stretched to double its lengt What will be its new resistivity ? (*H.S.S.C.E. 1998 ; C.B.S.E. 199*

Ans. The resistivity of a wire depends on the nature its material. The increase in length of the wire will not affe its resistivity.

Q. 1.18. Two wires A and B are of the same metal ar of the same length have their areas of cross-section in tl ratio of 2 : 1. If the same potential difference is applie across each wire in turn, what will be the ratio of tl currents flowing in A and B ? (*C.B.S.E. 199*

Ans. The two wires, having areas of cross-section in tl ratio 2 : 1, possess resistances in the ratio 1 : 2. It is becaus resistance of a wire is inversely proportional to its area cross-section. Since $I = \dfrac{V}{R}$ *i.e.* $I \propto \dfrac{1}{R}$ the currents in the tw wires will be in ratio 2 : 1, when the same potential differen is applied across the two wires.

Q. 1.19. Two wires A and B of same metal have tl same area of cross-section and have their lengths in the rat 2 : 1. What will be the ratio of currents flowing throug them, when the same potential difference is applied acro length of each of them ? (*C.B.S.E 199*

Ans. The two wires having their lengths in the ratio 1, possess resistances also in the ratio 2 : 1. It is becaus resistance of a wire is directly proportional to its length. Sin $I = \dfrac{V}{R}$ *i.e.* $I \propto \dfrac{1}{R}$ the currents in the two wires will be in tl ratio 1 : 2, when same potential difference is applied acro the two wires.

Q. 1.20. Draw a graph to show the variation of resi tance of a metal wire as a function of its diameter, keepi length and temperature constant. (*C.B.S.E. 1999*

Ans. We know, $R = \rho\frac{l}{A} = \rho\frac{l}{\pi D^2/4}$

or $R \propto \frac{1}{D^2}$

The graph between R and D will be as shown in Fig. 1.44.

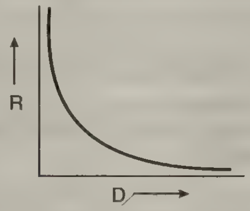

Fig. 1.44

Q. 1.21. Name the units of conductance and conduc- rity. (*I.S.C.E. 1996 ; H.P.S.S.C.E. 1995*)

Ans. The unit of conductance is **simen** and that of nductivity is **simen metre^{-1}**.

Q. 1.22. How does the conductance of a semiconduc- ig material change with rise in temperature ? (*C.B.S.E. 1998*)

Ans. The resistance of a semiconducting material creases on increasing temperature. Likewise, the conduc- nce of such a material increases due to rise in temperature.

Q. 1.23. What do you mean by temperature coefficient resistance ?

Ans. *The change in resistance per unit resistance per degree e or fall in temperature is called temperature coefficient of the istance.*

Q. 1.24. Of metals and alloys, which has greater value temperature coefficient ?

Ans. The value of α is more for metals than that for oys. For example, for copper, $\alpha = 4 \times 10^{-3}$ °C^{-1} and for nganin, $\alpha = 15 \times 10^{-6}$ °C^{-1}.

Q. 1.25. Why is manganin used for making standard sistors ? Give two reasons.

(*P.S.S.C.E. 1999 S ; H.S.S.C.E. 1999 ; C.B.S.E. 1995*)

Ans. Being an alloy, its resistivity is very high and nperature coefficient of resistance is very low.

Q. 1.26. Name the materials used for making standard sistance. Give reasons for this choice.

Ans. The alloys, such as manganin, constantan or chrome are used for making standard resistance. The alloys e used for this purpose for the reason that they possess high sistivity and low temperature coefficient of resistance.

Q. 1.27. Name any one material having a small value temperature coefficient of resistance. Write one use of is material. (*C.B.S.E. 1997*)

Ans. An alloy, such as nichrome, has a very small value temperature coefficient of resistance 4×10^{-4} °C^{-1}. Because this, it is used to make standard resistance.

Q. 1.28. Is the value of temperature coefficient of sistance always positive ?

Ans. No, it is positive only for metals and alloys. For miconductors and insulators, the value of α is negative.

Q. 1.29. What is a thermistor ?

(*P.S.S.C.E. 1999 , 2000 ; H.S.S.C.E. 1994*)

Ans. *A heat sensitive resistor, whose resistance varies preciably with temperature, is called a thermistor.*

Q. 1.30. What is a superconductor ?

(*P.S.S.C.E. 2000, 1999, 1998 S*)

Ans. *A conductor, which loses all signs of resistance on being cooled to its critical temperature, is called a super-conductor.*

Q. 1.31. What is meant by critical temperature in reference to superconductivity ?

Ans. The temperature of the conductor, at which all signs of its resistance disappear, is called critical temperature.

Q. 1.32. What are the carriers of current in a super-conductor ?

Ans. The carriers of current in a superconductor are mutually coherent electrons.

Q. 1.33. State two applications of superconductors.

(*P.S.S.C.E. 2002, 2000, 1995*)

Ans. 1. Superconductors can be used to transmit electric power without any loss of electric energy.

2. They can be used to produce very intense magnetic field without any expenditure of electric energy.

Q. 1.34. Why are resistances connected in series and in parallel.

Ans. The resistances are connected in series to increase the resistance of the circuit ; while they are connected in parallel, when resistance of the circuit is to be decreased.

Q. 1.35. A wire has a resistance of 90 Ω and it is cut into three pieces having equal lengths. If these are now connected in parallel, find the resistance of the combination so formed. (*P.S.S.C.E. 1997 ; H.S.S.C.E. 1997*)

Ans. When the wire having resistance of 90 Ω is cut into three equal pieces, each piece will be of resistance $\frac{90}{3}$ *i.e.* 30 Ω. If R_P is resistance of their parallel combination, then

$$\frac{1}{R_P} = \frac{1}{30} + \frac{1}{30} + \frac{1}{30} = \frac{1}{10} \quad \text{or} \quad R_p = 10\ \Omega$$

Q. 1.36. Given the resistances of 1 Ω, 2 Ω and 3 Ω. How will you combine them to get an equivalent resistance of 6 Ω and 6/11 Ω ?

Ans. In order to obtain an equivalent resistance of 6 Ω, the given resistances should be connected in series and to get 6/11 Ω, these resistances should be connected in parallel.

Q. 1.37. A student obtains resistances of 3, 4, 12 and 16 ohm using two metallic resistance wires, either separately or joined together. What is the value of resistance of each of these wires ? (*C.B.S.E. 1997*)

Ans. When two resistances are connected in series, the equivalent resistance is always greater than the individual resistances. On the other hand, when they are connected in parallel, the equivalent resistance is always less than either of them. Hence, of the measurements 3, 4, 12 and 16 Ω ; 16 Ω represent R_s and 3 Ω represents R_P. Obviously, the resistances of the two wires are 4 Ω and 12 Ω.

Q. 1.38. Define electromotive force (e.m.f.) of a cell.

(*P.S.S.C.E. 2002, 2000, 1999, 1998 S ; H.S.S.C.E. 1997 S*)

Ans. *The potential difference between two poles of a cell, when no current is drawn from it, is called electromotive force (e.m.f.) of the cell.*

1.39. On what factors does the internal resistance of a cell depend ? (*P.S.S.C.E. 2001*)

Ans. Internal resistance of a cell depends on the following factors :

1. The nature of electrolyte

2. The nature of electrodes
3. The distance between electrodes
4. The area of electrodes inside the electrolyte.

Q. 1.40. A cell of e.m.f. 2 V and internal resistance 0.1 Ω is connected to a 3·9 Ω external resistance. What will be the potential difference across the terminals of the cell ? *(C.B.S.E. 2001 S)*

Ans. Here, $E = 2\text{ V}$; $r = 0.1\ \Omega$ and $R = 3.9\ \Omega$

The terminal potential difference is given by

$$V = \frac{E}{R+r}R = \frac{2 \times 3{\cdot}9}{3{\cdot}9 + 0{\cdot}1} = 1{\cdot}95\text{ V}$$

Q. 1.41. A low voltage supply, from which one needs high currents, must have very low resistance. Why ? *(Text Question)*

Ans. The maximum current that can be drawn from a voltage supply is given by

$$I_{max} = \frac{E}{r}$$

Obviously, I_{max} will be large, if r is small.

Q. 1.42. A high voltage supply (H.T.) must have a very large internal resistance. Why ? *(Text Question)*

Ans. If the circuit containing the H.T. supply gets short circuited accidentally, the current in the circuit will not excee the safe limit, in case the internal resistance of H.T. supply very large.

Q. 1.43. In what respect, does a nearly discharged lea acid secondary cell differ mainly from a freshly charged ce in its e.m.f. or in its internal resistance ? *(Text Questio*

Ans. It mainly differs in internal resistance. A nearl discharged lead acid secondary cell possesses a very hig internal resistance in addition to a lower value of e.m.f.

Q. 1.44. A car battery is of 12 V. Eight dry cells of 1.5 connected in series can give 12 V. But such cells are not use in starting a car. Why ? *(C.B.S.E. 2001*

Ans. To start a car, a very high current is required. A ca battery can provide the required high current due to very lo value of its internal resistance. When eight dry cells are joine in series, the internal resistance of the combination of the cel becomes very high. Due to high value of internal resistanc the current that can be drawn from the cells is very smal Hence, such cells cannot be used to start a car.

Q. 1.45. It is easier to start a car engine on a warm da than on a chilly day. Why ? *(Text Questio*

Ans. With increase in temperature (on a warm day), th internal resistance of the car battery decreases.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 1.01. A large number of free electrons are present metals. Why is there no current in the absence of electric field across it ? *(P.S.S.C.E. 1998 S)*

Ans. The motion of free electrons is random *i.e.* the electrons move in all directions haphazardly. When electric field is applied, each free electron experiences a force in a direction opposite to that of the field. Due to this, the electrons acquire drift velocity. There is a net flow of charge, which constitutes the current. In the absence of electric field, it does not happen so and hence there is no current.

Q. 1.02. The current I flows through a wire of radius r and the free electrons drift with a velocity v_d. What is the drift velocity of electrons through a wire of same material but having double the radius, when a current 2 I flows through it ?

Ans. Let n be the electron density of the material of the wire.

Then, $$v_d = \frac{I}{nAe} = \frac{I}{n \times \pi r^2 \times e} \qquad ...(i)$$

Let v_d' be drift velocity of electrons in the second wire.

Then, $$v_d' = \frac{I'}{nA'e}$$

Here, $I' = 2I$ and $A' = \pi(2r)^2 = 4\pi r^2$

$$\therefore \quad v_d' = \frac{2I}{n \times 4\pi r^2 \times e} = \frac{1}{2}\frac{I}{n \times \pi r^2 e} \qquad ...(ii)$$

From equations (*i*) and (*ii*), we have

$$v_d' = v_d/2$$

Q. 1.03. What happens to the drift velocity (v_d) of electrons and to the resistance (R), if length of a conductor is doubled (keeping potential difference unchanged) ? *(C.B.S.E. 2002)*

Ans. Drift velocity of electrons is given by

$$v_d = \frac{eE}{m}\tau$$

If V is potential difference across the conductor of lengt l, then

$$E = \frac{V}{l}$$

Therefore, $$v_d = \frac{eV}{ml}\tau$$

As l is doubled (keeping potential difference unchar ged), the drift velocity will become **half** of the initial valu

As R is directly proportional to length, the resistance w become **double** of initial value, when length is doubled.

Q. 1.04. If the current supplied to a variable resistor constant, draw a graph between voltage and resistance. *(I.S.C.E. 199*

Ans. From Ohm's law, $V = IR$

If a constant current is passed, then the above relatio represents a straight line passing through origin. Hence, whe a constant current is passed through a variable resistor, th graph will be as shown in Fig. 1.45.

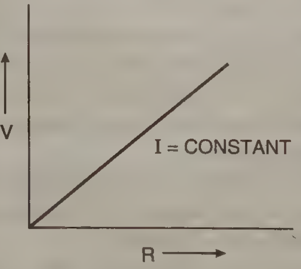

Fig. 1.45

Q. 1.05. Deduce dimensional formula for potenti difference. *(H.P.S.S.C.E. 199*

Ans. Now, potential difference V,

$$= \text{work done per unit charge}$$

$$\therefore \quad [V] = \frac{\text{work}}{\text{charge}} = \frac{\text{work}}{\text{current} \times \text{time}}$$

$$= \frac{[M\,L^2\,T^{-2}]}{[A] \times [T]} = [M\,L^2\,T^{-3}\,A^{-1}]$$

Q. 1.06. What are ohmic and non-ohmic resistors ? Give ne example of each. *(H.S.S.C.E. 2002)*

Ans. Ohmic resistor. *A resistor, which obeys ohm's law is lled an ohmic resistor.* For example, resistance possessed by metallic conductor is ohmic in nature.

Non-ohmic resistor. *A resistor, which does not obey ohm's w, is called a non-ohmic resistor.* For example, resistance ssessed by a semiconductor diode is non-ohmic in nature.

Q. 1.07. Define resistivity of a material and discuss the ctors on which it depends. *(H.S.S.C.E. 1997 S)*

Ans. *The resistivity of the material of a conductor is defined the resistance offered by a wire of this material of unit length and it area of cross-section.*

The resistivity of a conductor is given by

$$\rho = \frac{m}{n\,e^2\,\tau}$$

Thus, the resistivity of the material of a conductor varies

(*i*) inversely as the value of number of electrons per unit volume in the conductor.

(*ii*) inversely as the value of average relaxation time of the free electrons inside the conductor.

The value of n depends upon the nature of the material the conductor, while the average relaxation time depends on the temperature of the material.

Q. 1.08. Define resistivity of a material. Does it depend temperature ? *(C.B.S.E. 1992)*

Ans. For definition of resistivity, refer to section 1.09.

Yes, resistivity of a material depends on temperature.

Q. 1.09. Find out the resistivity of a conductor in which current density $2{\cdot}5 \times 10^6$ A m^{-2} is found to exist, when an ectric field of 15 V m^{-1} is applied on it. *(I.S.C.E. 1998)*

Ans. Let l and A be length and area of cross-section of e conductor respectively.

Here, current density, $\frac{I}{A} = 2{\cdot}5 \text{ A m}^{-2}$;

electric field, $\frac{V}{l} = 15 \text{ V m}^{-1}$

Now, resistivity, $\rho = R \cdot \frac{A}{l} = \frac{V}{I} \cdot \frac{A}{l} = \frac{V/l}{I/A}$

$$= \frac{15}{2{\cdot}5 \times 10^6} = 6 \times 10^{-6}\ \Omega\text{ m}$$

Q. 1.10. A wire of resistance 1 ohm is stretched to uble its length. What is the new resistance ?

(H.P.S.S.C.E. 2002, 1998 S ; P.S.S.C.E. 1995 ; C.B.S..E. 1994)

Ans. Let the wire be of length l and area of cross-section If resistivity of its material is ρ, then

original resistance of the wire, $R_1 = \rho\,\frac{l}{A}$

When the wire is stretched to double its length, then its ea of cross-section reduces to half of the initial area of cross-ction. Therefore, new resistance of the wire,

$$R_2 = \rho\,\frac{2l}{A/2} = 4\,\pi\,\frac{l}{A} = 4\,R_1$$

Since $R_1 = 1\,\Omega$, we have

$$R_2 = 4 \times 1 = 4\,\Omega$$

Q. 1.11. Two wires of equal lengths, one of copper and the other of manganin have the same resistance. Which wire is thicker ? *(C.B.S.E. 1995, 1991)*

Ans. Let ρ_1 and ρ_2 be resistivities of copper and manganin and A_1 and A_2 be the areas of cross-section of the wires made of copper and manganin respectively. Since two wires have equal lengths and have the same resistance,

$$\rho_1\,\frac{l}{A_1} = \rho_2\,\frac{l}{A_2} \quad \text{or} \quad \frac{A_1}{A_2} = \frac{\rho_1}{\rho_2}$$

Since resistivity of copper (ρ_1)is less than that of manganin (ρ_2), it follows that area of cross-section of copper wire(A_1) is less than that of manganin wire (A_2). Thus, **manganin** wire is thicker.

Q. 1.12. Compare the resistance of two wires of same material. Their lengths are in the ratio 2 : 3 and their diameters are in the ratio 1 : 2.

Ans. Let the lengths of the two wires be $2\,l$ and $3\,l$ and their diameters be D and 2 D respectively. Let ρ be the resistivity of the material of the two wires. Now,

$$R = \rho\,\frac{l}{A} = \rho\,\frac{l}{\pi\,D^2/4} = 4\,\rho\,\frac{l}{\pi\,D^2}$$

Therefore, $R_1 = 4\,\rho\,\frac{2l}{\pi\,D^2} = 8\,\rho\,\frac{l}{\pi\,D^2}$

and $R_2 = 4\,\rho\,\frac{3l}{\pi\,(2\,D)^2} = 3\,\rho\,\frac{l}{\pi\,D^2}$

Hence, $\frac{R_1}{R_2} = \left(8\,\rho\,\frac{l}{\pi\,D^2}\right) \Big/ \left(3\,\rho\,\frac{l}{\pi\,D^2}\right) = \frac{8}{3}$

Q. 1.13. A given wire having resistance R is stretched so as to reduce its diameter to half of its previous value. What will be its new resistance ? *(H.S.S.C.E. 2002)*

Ans. Let l be length and A be area of cross-section of the wire. Then,

$$R = \rho\,\frac{l}{A} \qquad \text{...}(i)$$

When the diameter of the wire is reduced to half of its previous value, its new area of cross-section will become one fourth *i.e.*

$$A' = A/4$$

If l' is new length of the wire, then

$$l'\,A' = l\,A \quad \text{or} \quad l' \times A/4 = l\,A \quad \text{or} \quad l' = 4\,l$$

Therefore, new resistance of the wire,

$$R' = \rho\,\frac{l'}{A'} = \rho\,\frac{4l}{A/4}$$

or $$R' = 16\,\rho\,\frac{l}{A} \qquad \text{...}(ii)$$

From equation (*i*) and (*ii*), we have

$$R' = 16\,A$$

Q. 1.14. A potential difference V is applied across a conductor of length L and diameter D. How are the electric field E and the resistance R of conductor affected, when in turn (*a*) V is halved (*b*) L is halved and (*c*) D is doubled ? Justify your answer in each case. *(C.B.S.E. 1997)*

Ans. Fig. 1.46 shows a wire of length L and diameter D, across the two ends of which, a potential difference V has been applied.

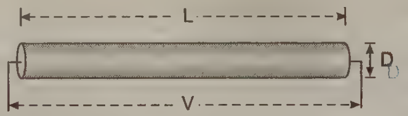

Fig. 1.46

If ρ is resistivity of the material of the wire, then resistance of the wire,

$$R = \rho \frac{L}{A} = \rho \frac{L}{\pi D^2/4}$$

or $$R = \rho \frac{4L}{\pi D^2}$$

Also, electric field along the wire, $E = \frac{V}{L}$

(a) When V is halved : There is **no effect** on resistance of the wire.

When potential difference is made $V' = V/2$, the electric field will become

$$E' = \frac{V'}{L} = \frac{V/2}{L} = \frac{1}{2}\left(\frac{V}{L}\right) = \frac{E}{2}$$

i.e. electric field will also get **halved.**

(b) When L is halved : When length is made $L' = \frac{L}{2}$, the resistance of wire will become

$$R' = \rho \frac{L/2}{\pi D^2} = \frac{1}{2}\left(\rho \frac{L}{\pi D^2}\right) = \frac{R}{2}$$

i.e. resistance of wire will also get **halved.**

Also, the electric field will become,

$$E' = \frac{V}{L'} = \frac{V}{L/2} = 2\left(\frac{V}{L}\right) = 2E$$

i.e. electric field will become **twice.**

(c) When D is doubled : When diameter of the wire is made $D' = 2D$, the resistance of the wire will become,

$$R' = \rho \frac{L}{\pi D'^2} = \rho \frac{L}{\pi (2D)^2} = \frac{1}{4}\left(\rho \frac{L}{\pi D^2}\right) = \frac{R}{4}$$

i.e. resistance of wire will become **onefourth.**

There is **no effect** on the electric field.

Q. 1.15. Write down a simple relationship to show the variation of resistance with temperature. Define temperature coefficient of resistance. (*I.S.C.E. 1995*)

Ans. The resistance of a metallic conductor at temperature θ °C is given by

$$R = R_0 (1 + \alpha \theta),$$

where R_0 is its resistance at 0°C and α, temperature coefficient of the material of the conductor.

From the above equation, we have

$$\alpha = \frac{R - R_0}{R \times \theta}$$

Hence, *temperature coefficient of the material of a wire is defined as the increase in resistance per unit resistance of the conductor at 0°C per degree rise of temperature.*

Q. 1.16. The variation of resistance of a metallic conductor with temperature is given in Fig. 1.47. (*i*) Calculate the temperature coefficient of resistance from the graph. (*ii*) State why the resistance of the conductor increas with rise in temperature. (*C.B.S.E. 1998*

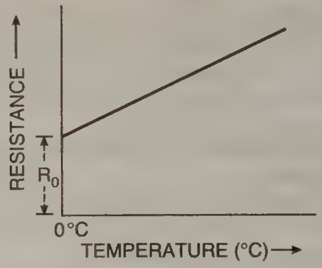

Fig. 1.47

Ans. Consider a point A on the resistance-temperatu graph [Fig. 1.48].

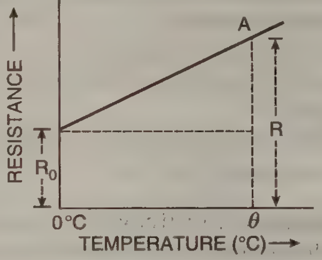

Fig. 1.48

Let R be resistance of the conductor and θ be temperature corresponding to point A on the graph.

(*i*) Temperature coefficient of the conductor,

$$\alpha = \frac{R - R_0}{R \times \theta}$$

(*ii*) The resistance of a wire is given by

$$R = \rho \frac{l}{A} = \frac{m}{ne^2\tau} \cdot \frac{l}{A}$$

When temperature of conductor is increased, its avera relaxation time decreases due to increase in frequency collision of electrons with atoms and ions. Since $R \propto \frac{1}{\tau}$, resistance of the conductor increases with rise in temperatu

Q. 1.17. The voltage-current variation of two metal wires X and Y at constant temperature are as shown in F 1.49. Assuming that the wires have the same length a same diameter, explain which wire will have a larg resistivity and why ? (*C.B.S.E. 1998*

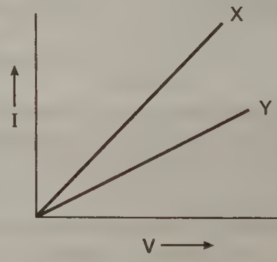

Fig. 1.49

Ans. Suppose that the two wires X and Y poss resistances R_1 and R_2 respectively. Further, suppose that th materials are of resistivity ρ_1 and ρ_2 respectively. Since two wires are of same length l and area A,

$$R_1 = \rho_1 \frac{l}{A} \text{ and } R_2 = \rho_2 \frac{l}{A}$$

Suppose that a potential difference V is applied across e two wires X and Y as shown in Fig. 1.50.

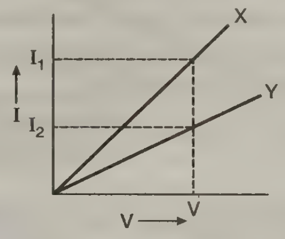

Fig. 1.50

It follows that current through wire X will be greater han that through wire Y *i.e.* $I_1 > I_2$.

The resistances of the wires X and Y are given by

$$R_1 = \frac{V}{I_1} \quad \text{and} \quad R_2 = \frac{V}{I_2}$$

Since $I_1 > I_2$, it follows that $R_1 < R_2$

$$\text{i.e.} \quad \rho_1 \frac{l}{A} < \rho_2 \frac{l}{A} \quad \text{or} \quad \rho_1 < \rho_2$$

e. wire Y has greater resistivity.

Q. 1.18. V-I graph for a metallic wire at two different emperatures T_1 and T_2 is as shown in the Fig. 1.51. Which f the two temperatures T_1 and T_2 is higher and why ? (*C.B.S.E. 1998*)

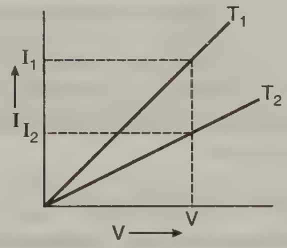

Fig. 1.51

Ans. If the same potential difference V is applied, current qual to I_1 and I_2 will flow through the wire, when its emperature is kept at T_1 and T_2 respectively. Since $R = \frac{V}{I}$, follows that resistance of the wire is more at temperature $_2$. Further, as in case of metals, the resistance increases with ise of temperature, $T_2 > T_1$.

Q. 1.19. A piece of copper and another of germanium re cooled from room temperature to 100 K. What will appen to their conductivities ? Explain. (*P.S.S.C.E. 1993*)

Ans. Copper possesses positive temperature coefficient, vhereas the germanium possesses negative temperature oefficient. Therefore, if they are cooled from room temperaure to 100 K, the resistance of copper will decrease and that f germanium will increase. In other words, the conductivity f copper increases and that of germanium decreases.

Q. 1.20. What is the total value of resistance between oints A and B in the network shown in Fig. 1.52 ?

Ans. If a battery is connected across the points A and B, hen same current will flow through all the resistances and ence the five resistances each of value R are in series.

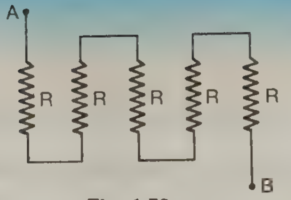

Fig. 1.52

Therefore, total value of resistance between points A and B is equal to 5 **R**.

Q. 1.21. In how many equal parts a wire having resistance of 100 Ω be cut, so that we may obtain a resistance of 1 Ω by connecting them in parallel ?

Ans. Suppose that the resistance of 100 Ω is cut into n equal parts. Then, the resistance of each part will be $\frac{100}{n}\ \Omega$. When these n parts are connected in parallel, the effective resistance becomes 1 Ω.

$$\therefore \quad \frac{n}{100} + \frac{n}{100} + \frac{n}{100} + \ldots\ldots n \text{ times} = \frac{1}{1}$$

$$\text{or} \quad \frac{n^2}{100} = 1 \quad \text{or} \quad n = 10$$

Q. 1.22. When two resistances are in series, they have value 25 Ω and in parallel 4 Ω. Find each. (*H.S.S.C.E. 1997*)

Ans. Let R_1 and R_2 be the two resistances.

Here, $R_s = 25\ \Omega$; $R_p = 4\ \Omega$

$$\therefore \quad R_1 + R_2 = 25 \quad \text{and} \quad \frac{R_1 R_2}{R_1 + R_2} = 4$$

Solving the above two equations, it can be obtained that

$$\mathbf{R_1 = 5\ \Omega \quad \text{and} \quad R_2 = 20\ \Omega}$$

Q. 1.23. A set of n identical resistors, each of resistance R ohm, when connected in series have an effective resistance of X ohm and when the resistors are connected in parallel, the effective resistance is Y ohm. Find the relation between R, X and Y. (*C.B.S.E. 1996*)

Ans. When n resistors, each of resistance, R are connected in series, then

$$X = n R \qquad \ldots(i)$$

When n resistors, each of resistance R are connected in parallel, then

$$Y = \frac{R}{n} \qquad \ldots(ii)$$

Multiplying equations (*i*) and (*ii*), we have

$$X Y = n R \times \frac{R}{n} = R^2$$

$$R = \sqrt{X Y}$$

Q. 1.24. You have three resistances of value R each. How will you connect these for obtaining a total resistance of 3 R/2? Show this connection by a diagram. (*P.S.S.C.E. 1996 S*)

Ans. A parallel combination of two resistors, each of resistance R should be put in series with the third resistor of resistance R as shown in Fig. 1.53.

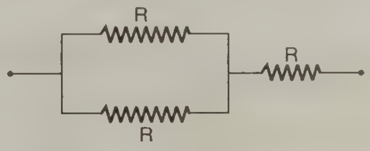

Fig. 1.53

Q. 1.25. Three resistors, each of resistance 4 Ω are connected in parallel. Five resistors, each of resistance 8 Ω are connected in parallel. Another three resistors, each of resistance 10 Ω are in parallel. If these three parallel combinations are in series, find the effective resistance of the circuit. *(Karnataka, 1988)*

Ans. The effective resistance of three resistors each of 4 Ω in parallel, $R_1 = \frac{4}{3} = 1{\cdot}333\ \Omega$

The effective resistance of five resistors each of 8 Ω in parallel, $R_2 = \frac{8}{5} = 1{\cdot}6\ \Omega$

The effective resistance of three resistors each of 10 Ω in parallel, $R_3 = \frac{10}{3} = 3{\cdot}333\ \Omega$

As the three sets are connected in series, the effective resistance is given by

$$R = R_1 + R_2 + R_3 = 1{\cdot}333 + 1{\cdot}6 + 3{\cdot}333$$
$$= 6{\cdot}266\ \Omega$$

Q. 1.26. Given *n* resistors each of resistance R. How will you combine them to get the (*i*) maximum, (*ii*) minimum effective resistance ? What is the ratio of the maximum to the minimum resistance ? *(Text Question)*

Ans. (*i*) The resistance will be maximum, when resistors are connected in series. Therefore, maximum resistance,

$$R_{max} = R + R + R + \ldots\ldots n \text{ times} = nR$$

(*ii*) The resistance will be minimum, when resistors are connected in parallel. Therefore, minimum resistance,

$$\frac{1}{R_{min}} = \frac{1}{R} + \frac{1}{R} + \frac{1}{R} + \ldots\ldots n \text{ times} = \frac{n}{R}$$

or $$R_{min} = \frac{R}{n}$$

Now, $$\frac{R_{max}}{R_{min}} = \frac{nR}{R/n} = n^2$$

Q. 1.27. A and B are two poins on a circular ring made of uniform wire of resistance R. If the part AB of the ring subtends an angle θ at the centre C of the ring [Fig. 1.54], find the resistance of the ring between points A and B.

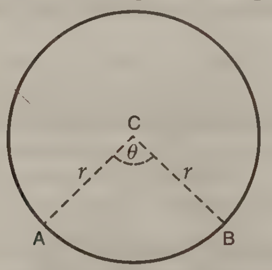

Fig. 1.54

Ans. Let *r* be the radius of the ring. Then,

resistance per unit length of the ring $= \frac{R}{2\pi r}$

Let l_1 be the length of the part of the ring subtending angle θ at the centre of the ring. Then,

$$l_1 = r\theta$$

If R_1 is resistance of the part of the ring subtending angle θ at the centre of the ring, then

$$R_1 = l_1 \times \frac{R}{2\pi r} = r\theta \times \frac{R}{2\pi r} = \frac{R\theta}{2\pi}$$

The other part of the ring subtends an angle $(2\pi - \theta)$ the centre of the ring. Its length will be $r(2\pi - \theta)$ and resistan will be

$$R_2 = r(2\pi - \theta) \times \frac{R}{2\pi r} = \frac{R(2\pi - \theta)}{2\pi}$$

Between the points A and B, the resistances of the tw parts of the ring are in parallel. Therefore, effective resistan of the ring between points A and B,

$$R_{eff} = \frac{R_1 R_2}{R_1 + R_2} = \frac{(R\theta/2\pi) \times [R(2\pi - \theta)/2}{(R\theta/2\pi) + [R(2\pi - \theta)/2}$$
$$= \frac{(2\pi - \theta)\theta}{4\pi^2} R$$

Q. 1.28. A uniform wire of resistance R is shaped in a regular *n* sided polygon, where *n* is even. Find t equivalent resistance between (*a*) opposite corners of t polygon and (*b*) adjacent corners of polygon.

Ans. When a uniform wire of resistance R is shaped in a regular *n* sided polygon,

the resistance of each side of polygon $= \frac{R}{n}$

(*a*) Resistance of polygon between opposite corne Let R_1 and R_2 be resistances of the two parts of the polygo Then,

$$R_1 = R_2 = \frac{n}{2} \times \frac{R}{n} = \frac{R}{2}$$

Since the two parts are in parallel with each other, t resistance of the polygon between opposite corners,

$$R' = \frac{R_1 R_2}{R_1 + R_2} = \frac{R/2 \times R/2}{R/2 + R/2} = \frac{R}{4}$$

(*b*) Resistance of polygon between adjacent corne The polygon is equivalent to the combination of two resi tances R_1 and R_2, where

R_1 = resistance of one side $= \frac{R}{n}$

and R_2 = resistance of $(n - 1)$ sides connected in serie

$$= \frac{(n-1)R}{n}$$

Therefore, resistance of the polygon between adjace corners,

$$R'' = \frac{R/n \times (n-1)R/n}{R/n + (n-1)R/n} = \frac{(n-1)R}{n^2}$$

Q. 1.29. A battery of e.m.f. E and internal resistanc sends a current I_1 and I_2, when connected to an extern resistance of R_1 and R_2 respectively. Find the e.m.f. a internal resistance of the battery.

Ans. Now, $I_1 = \frac{E}{R_1 + r}$

or $E = I_1(R_1 + r)$ ...(

Also, $I_2 = \frac{E}{R_2 + r}$

or $E = I_2(R_2 + r)$ ...(

From equations (*i*) and (*ii*), we have

$$I_1(R_1 + r) = I_2(R_2 + r)$$

or $$r = \frac{I_1 R_1 - I_2 R_2}{I_2 - I_1}$$

From equation (*i*), we have

$$E = I_1 (R_1 + r) = I_1 \left[R_1 + \frac{I_1 R_1 - I_2 R_2}{I_2 - I_1} \right]$$

or $$E = \frac{I_1 I_2 (R_1 - R_2)}{I_2 - I_1}$$

Q. 1.30. The storage battery of a car has an e.m.f. of 12 If the internal resistance of the battery is 0·4 Ω, what is e maximum current that can be drawn from the battery ? (*Text Question*)

Ans. Here, $E = 12\ V ; r = 0{\cdot}4\ \Omega$

The maximum current is drawn from the battery, when external resistance in the circuit is zero *i.e.* R = 0.

$$\therefore \qquad I_{max} = \frac{E}{r} = \frac{12}{0{\cdot}4} = \mathbf{30\ A}$$

Q. 1.31. Is internal resistance a defect of a cell ? Explain.

Ans. The internal resistance of a cell is not a defect of the cell. It is an inherent characteristic of the cell. The cell possesses internal resistance, because the ions have to move against the background of other ions and the neutral atoms of the electrolyte.

TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 1.01. A wire is carrying current. Is it charged ? Why ?

Ans. No. Electric current is the flow of free electrons in e conductor. At any instant, the number of electrons leaving e wire is always equal to the number of electrons flowing om the battery into it. Hence, the net charge on the wire is ro.

Q. 1.02. The electron drift speed is estimated to be very low. How there is current established almost the stant a circuit is closed ? (*Text Question*)

Ans. The information about beginning of the flow of rrent is transmitted through the propagation of ectromagnetic waves (electric impulse) and not with the ift velocity of the electrons. Hence, the electric bulb turns almost instantly, when the switch is closed.

Q. 1.03. Two wires of the same material having lengths in the ratio of 1 : 2 and diameters in the ratio 2 : 3 are connected in series with an accumulator. ompute the ratio of the potential difference across the two ires. (*C.B.S.E. Sample Q. Paper*)

Ans. Let lengths of the two wires 1 and 2 be $l_1 = x$ and $= 2\ x$ and their diameters be $D_1 = 2\ D$ and $D_2 = 3\ D_1$ spectively. Let ρ be resistivity of the material of the two ires.

Then, resistance of wire 1,

$$R_1 = \rho \frac{l_1}{A_1} = \rho_1 \frac{l_2}{\pi r_2^2} = \rho \frac{x}{\pi \left(\frac{2D}{2}\right)^2} = \rho \frac{x}{\pi D^2}$$

The resistance of wire 2,

$$R_2 = \rho \frac{l_2}{A_2} = \rho_1 \frac{l_2}{\pi r_2^2} = \rho \frac{2x}{\pi \left(\frac{3D}{2}\right)^2} = \rho \frac{8x}{9 \pi D^2}$$

Then, total resistance of the series circuit, $R = R_1 + R_2$

or $$R = \rho \frac{x}{\pi D^2} + \rho \frac{8x}{9 \pi D^2} = \rho \frac{17x}{9 \pi D^2}$$

Let E be e.m.f. of the accumulator. Then,

current in the circuit, $I = \frac{E}{R} = \frac{E}{\rho} \cdot \frac{9 \pi D^2}{17 x}$

Now, potential difference across wire 1,

$$V_1 = I R_1 = \frac{E}{\rho} \cdot \frac{9 \pi D^2}{17 x} \cdot \rho \frac{x}{\pi D^2} = \frac{9 E}{17}$$

and potential difference across wire 2,

$$V_2 = I R_2 = \frac{E}{\rho} \cdot \frac{9 \pi D^2}{17 x} \cdot \rho \frac{8x}{9 \pi D^2} = \frac{8 E}{17}$$

$$\therefore \qquad \frac{V_1}{V_2} = \frac{9 E}{17} \times \frac{17}{8 E} = \frac{9}{8}$$

Q. 1.04. Resistivity of the material of a conductor of uniform area of cross-section varies along its length as $\rho = \rho_0 (1 + \alpha x)$. Find the resistance of the conductor, if its length is L and area of cross-section is A.

Sol. Consider a length element *dx* of the conductor at a distance *x* from its one end. Then, small resistance of the length element *dx* of the conductor,

$$dR = \rho \frac{dx}{A} = \rho_0 \ (1 + \alpha x) \frac{dx}{A}$$

The resistance of the whole length of the conductor,

$$R = \int_0^L dR = \int_0^L \rho_0 (1 + \alpha x) \frac{dx}{A} = \frac{\rho_0}{A} \left[\int_0^L dx + \alpha \int_0^L x\, dx \right]$$

$$= \frac{\rho_0}{A} \left[\left| x \right|_0^L + \alpha \left| \frac{x^2}{2} \right|_0^L \right] = \frac{\rho_0}{A} \left[(L - 0) + \frac{1}{2} \alpha (L^2 - 0) \right]$$

$$= \frac{\rho_0}{A} \left(L + \frac{1}{2} \alpha L^2 \right)$$

Q. 1.05. A parallel plate capacitor having plates of area A separated by a distance *d* is first filled with a dielectric of permittivity ε and then with an electrolyte of conductivity σ. Find the ratio between the capacitance of the capacitor in the first case and its conductance in the second.

Ans. ***When the dielectric is filled between the plates of capacitor*** : The capacitance of the capacitor is given by

$$C = \frac{\varepsilon A}{d} \qquad \text{...(}i\text{)}$$

When the electrolyte is filled between the plates of capacitor : The capacitor acts as a conductor of cross-sectional area A, length *d* and resistivity $\frac{1}{\sigma}$. Therefore, resistance of the capacitor is given by

$$R = \frac{1}{\sigma} \cdot \frac{d}{A}$$

If G is conductance of the capacitor, then

$$G = \frac{1}{R} = \frac{\sigma A}{d} \qquad \text{...(}ii\text{)}$$

Dividing equation (*i*) by (*ii*), we have

$$\frac{C}{G} = \frac{\varepsilon A}{d} \times \frac{d}{\sigma A} = \frac{\varepsilon}{\sigma}$$

Q. 1.06. At 0°C, the resistance of a conductor B is *n* times that of the conductor A. The temperature coefficients of resistance of the conductors A and B are α_1 and α_2 respectively. Find the resistance of the series combination of the two conductors at 0°C. Also, find the temperature coefficient of the resistance of the series combination of the two conductors.

Ans. Let R_0 be the resistance of conductor A at 0°C. Then, resistance of conductor B at 0°C, $R_0' = n\,R_0$

Let R and R′ be respectively the resistances of the conductors A and B at θ °C. Then,

$$R = R_0\,(1 + \alpha_1\,\theta)$$

and $$R' = R_0'\,(1 + \alpha_2\,\theta) = n\,R_0\,(1 + \alpha_2\,\theta)$$

If R_s is the resistance of the series combination of the two conductors at θ°C, then

$$R_s = R + R' = R_0\,(1 + \alpha_1\,\theta) + n\,R_0\,(1 + \alpha_2\,\theta)$$

or $$= R_0\,[(1 + n) + (\alpha_1 + n\,\alpha_2)\,\theta]$$

or $$R_s = (1+n)\,R_0\left[1 + \frac{\alpha_1 + n\,\alpha_2}{1+n}\,\theta\right] \qquad ...(i)$$

From equation (*i*) it follows that resistance of series combination of conductors A and B at 0°C is **(1 + *n*) R_0** and their temperature coefficient is equal to $\dfrac{\alpha_1 + n\,\alpha_2}{1+n}$

Q. 1.07. What should the resistances of the sections of a rheostat R_1, R_2 and R_3 be in order to change the current passing through an electrical appliance of resistance R = 30 Ω by 1 A [Fig. 1.55], when the rheostat slide is shifted from one contact to another ? The circuit is powered by a source of E = 120 V.

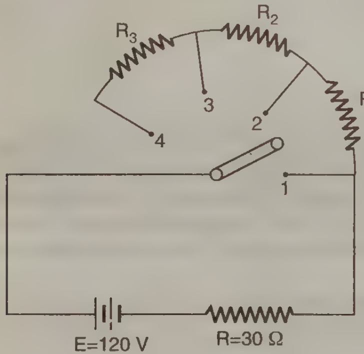

Fig. 1.55

Ans. ***When the rheostat slide is at terminal 1*** **:** When the slide is at terminal 1, the rheostat is completely out of the circuit. Then, current in the circuit,

$$I = \frac{E}{R} = \frac{120}{30} = 4\text{ A}$$

When the rheostat slide is at terminal 2 **:** Now, the resistor R_1 is included in the circuit. This should decrease current in the circuit by 1 A *i.e.* decrease to 4 – 1 *i.e.* 3 A. Thus,

$$\frac{E}{R + R_1} = 3 \quad \text{or} \quad \frac{120}{30 + R_1} = 3$$

or $$30 + R_1 = \frac{120}{3} = 40$$

or $$R_1 = 40 - 30 = \mathbf{10\ \Omega}$$

When the rehostat slide is at terminal 3 **:** As such, resistors R_1 and R_2 are included in the circuit and theref current should decrease to 3 – 1 = 2 A. Thus,

$$\frac{E}{R + R_1 + R_2} = 2 \quad \text{or} \quad \frac{120}{30 + 10 + R_2} =$$

or $$\frac{120}{40 + R_2} = 3 \quad \text{or} \quad 40 + R_2 = \frac{120}{2} =$$

or $$R_2 = 60 - 40 = \mathbf{20\ \Omega}$$

When the rheostat slide is at terminal 4 **:** With inclusion of resistors R_1, R_2 and R_3, the current should n decrease to 2 – 1 = 1 A. Thus,

$$\frac{E}{R + R_1 + R_2 + R_3} = 1 \quad \text{or} \quad \frac{120}{30 + 10 + 20 + R_3} =$$

or $$\frac{120}{60 + R_3} = 1 \quad \text{or} \quad 60 + R_3 =$$

or $$R_3 = 120 - 60 = \mathbf{60\ \Omega}$$

Note. In fact, the above arrangement of resistors for a conventional regulator (such as regulator used with electric fan) for regulating current in an electric circuit.

Q. 1.08. A circular ring having negligible resistanc used to connect four resistors of resistances 6 R, 6 6 R and R as shown in Fig 1.56. Find the equival resistance between points A and B.

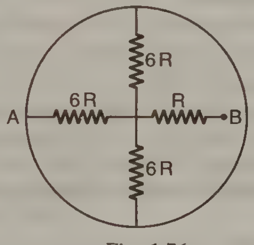

Fig. 1.56

Ans. The given network of resistors is equivalent to arrangement shown in Fig. 1.57.

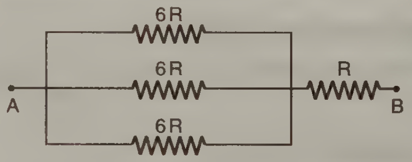

Fig. 1.57

Let R′ be the equivalent of resistance of the para combination of three resistors, each of resistance 6 R. Th

$$\frac{1}{R'} = \frac{1}{6R} + \frac{1}{6R} + \frac{1}{6R} = \frac{3}{6R} \quad \text{or} \quad R' = 2R$$

Therefore, equivalent resistance of the network betw points A and B

$$R_{equi} = 2R + R = \mathbf{3\ R}$$

Q. 1.09. What is the equivalent resistance betw points A and B of the circuit shown in Fig. 1.58 ?

(*I.I.T. 19*

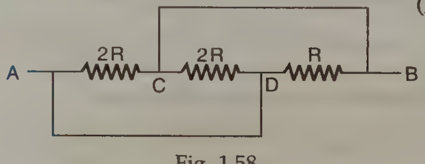

Fig. 1.58

Ans. The given circuit may be redrawn as shown in Fig.

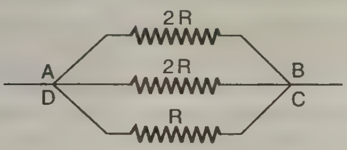

Fig. 1.59

The three resistances form a parallel combination. If R′ e equivalent resistance of the combination, then

$$\frac{1}{R'}=\frac{1}{2R}+\frac{1}{2R}+\frac{1}{R}=\frac{1+1+2}{2R}=\frac{2}{R}$$

or $$R'=\frac{R}{2}$$

10. Determine the equivalent resistance of the network wn in Fig. 1.60. *(Text Question)*

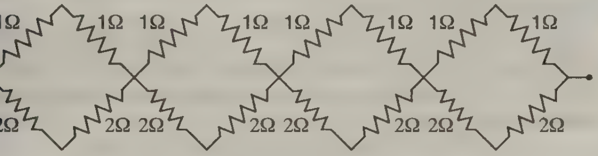

Fig. 1.60.

Sol. The network shown in Fig. 1.60 is a series combi- on of four units. One such unit is shown in the Fig. 1.61.

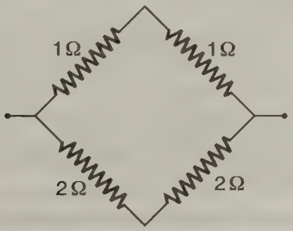

Fig. 1.61

llows that one such unit is equivalent to a parallel bination of two resistances of 2 Ω and 4 Ω [Fig. 1.62].

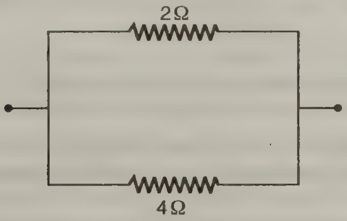

Fig. 1.62

Therefore, resistance of one such unit is given by

$$\frac{1}{R}=\frac{1}{2}+\frac{1}{4}=\frac{2+1}{4}=\frac{3}{4}$$

or $$R=\frac{4}{3}\,\Omega$$

Therefore, resistance of the total network (4 such units)

$$=4\times\frac{4}{3}=\frac{16}{3}\,\Omega$$

Q. 1.11. A battery of e.m.f. E and internal resistance r is connected to a variable external resistance R. Find value of R so that (*a*) current in the circuit is maximum (*b*) terminal potential across the battery is maximum. o, find the maximum value of current in case (*a*) and imum terminal potential difference in case (*b*).

Ans. (*a*) The current in the circuit,

$$I=\frac{E}{R+r}$$

It follows that current in the circuit will be maximum, when $R+r$ is minimum *i.e.* **R = 0.**

The maximum value of current,

$$I_{max}=\frac{E}{r+0}=\frac{E}{r}$$

(*b*) The terminal potential difference across the battery,

$$V=E-Ir=E-\frac{Er}{R+r}$$

It follows that terminal potential across the battery will be maximum, when $E\,r/R+r$ is minimum *i..e* **R = ∞.**

The maximum value of terminal potential difference,

$$V_{max}=E-\frac{Er}{\infty+r}=E$$

Q. 1.12. A secondary cell after long use has an e.m.f. 1·9 V and a large internal resistance of 380 Ω. What maximum current can be drawn from the cell ? Could the cell drive the starting motor of a car ? *(Text Question)*

Ans. Here, $E=1{\cdot}9$ V ; $r=380\ \Omega$

The maximum current that can be drawn corresponds to zero external resistance. Therefore,

$$I_{max}=\frac{1{\cdot}9}{380}=\mathbf{0{\cdot}005\ A}$$

A motor needs a current of 100 mA or so for a few seconds. Hence, it cannot be used to drive the starting motor of a car.

Q. 1.13. Two identical storage batteries having e.m.fs. of E and the same internal resistance r are connected as shown in Fig. 1.63. Determine the potential difference, which will be established between points A and B.

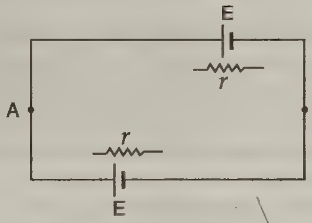

Fig. 1.63

Ans. As the two batteries are connected in series, total e.m.f. of the batteries, $E'=E+E=2E$ and total resistance of the circuit, $R=r+r=2r$

Therefore, current in the circuit,

$$I=\frac{E'}{R}=\frac{2E}{2r}=\frac{E}{r}$$

Now, potential difference between points A and B,

V_A-V_B = e.m.f. of the either cell
– potential drop across its internal resistance

$$=E-r\times\frac{E}{r}=E-E=0$$

Problem 1.14. A storage battery of e.m.f. 8·0 V and internal resistance 0·5 Ω is being charged by a 120 V d.c. supply using a series resistor of 15·5 Ω. What is the terminal voltage of the battery during charging ? *(Text Question)*

Sol. Here, $r=0{\cdot}5\ \Omega$; $R=15{\cdot}5\ \Omega$

When storage battery of e.m.f. 8·0 V is charged with a d.c. supply of 120 V, the net e.m.f. in the circuit,

$$E = 120 - 8{\cdot}0 = 112{\cdot}0 \text{ V}$$

Therefore, current in the circuit during charging,

$$I = \frac{E}{R+r} = \frac{112{\cdot}0}{15{\cdot}5+0{\cdot}5} = 7{\cdot}0 \text{ A}$$

Terminal voltage of the storage battery would be equal to the sum of its e.m.f. and potential difference across its internal resistance *i.e.*

terminal voltage = 8·0 + 0·5 × 7 = **11·5 V**

Q. 1.15. A storage battery is connected to a battery charger supplying V = 12·5 volt [Fig. 1.64]. The internal resistance of the storage battery is 1 Ω. What is the e.m.f. of the storage battery, if a current of 0·5 A flows through it during charging ? (*Text Question*)

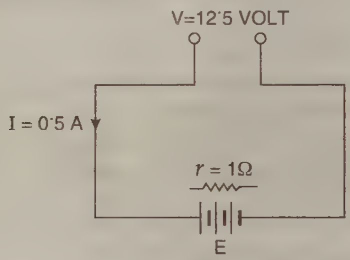

Fig. 1.64

Ans. Let E be the e.m.f. of the battery. The charging current I is opposed by the e.m.f. of the battery. According to Ohm's law,

$$V - E = I\,r$$

or $$E = V - I\,r = 12{\cdot}5 - 0{\cdot}5 \times 1 = \mathbf{12\ V}$$

Q. 1.16. When a secondary cell of e.m.f. 2·0 V is being charged by an external supply, is the terminal voltage of the secondary cell greater or less than 2·0 V ? (*Text Question*)

Ans. When a secondary cell is charged, the current during charging is in the direction of electrostatic field. As a result, the electrostatic field is greater than the non-electrostatic field existing inside the cell and hence the terminal voltage is greater than the e.m.f. of the secondary cell.

Also, refer to Conceptual SAQ. 1.14.

Q. 1.17. A dynamo has internal resistance $r = 0{\cdot}5\,\Omega$ and provides an e.m.f. E_1 = 240 V. It is connected to a storage battery of e.m.f. E_2 = 220 V and an external resistance R as shown in Fig. 1.65. At what maximum value of R will no current pass through the storage battery ? How will the battery operate, when the resistance R is larger or smaller than the above maximum value of R ?

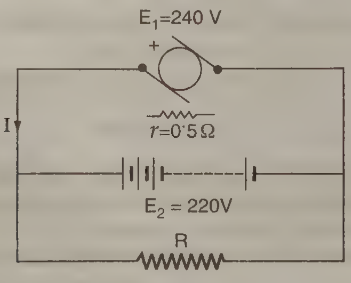

Fig. 1.65

Ans. Let R_{max} be the value of R, so that no current through the battery. As the entire current, say I, produc the dynamo passes through external resistance,

$$I = \frac{E_1}{R_{max}+r} = \frac{240}{R_{max}+0{\cdot}5}$$

Also, for no current to flow through battery, the pot difference between the poles of the dynamo should be to e.m.f. of the battery *i.e.*

$$E_1 - I\,r = E_2$$

or $$I = \frac{E_1 - E_2}{r} = \frac{240-220}{0{\cdot}5} = 40 \text{ A}$$

From equations (*i*) and (*ii*), we have

$$\frac{240}{R_{max}+0{\cdot}5} = 40 \quad \text{or} \quad R_{max} + 0{\cdot}5 = 6$$

or $$R_{max} = \mathbf{5{\cdot}5\ \Omega}$$

If $R > R_{max}$, battery will be charged and when R < battery will be discharged.

Q. 1.18. In the circuit shown in Fig. 1.66, each b is of 5 V and has an internal resistance of 0·2 Ω. will be the reading of an ideal voltmeter connected a battery ? (*I.I.T.*

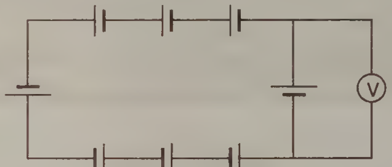

Fig. 1.66

Ans. Here, e.m.f. of each battery, E = 5 V

and internal resistance of each battery, $r = 0{\cdot}2\ \Omega$

If I is current in the circuit, then

reading of the voltmeter, $V = E - I\,r$,

where I is current in the circuit.

Now, $$I = \frac{\text{total e.m.f. of all the eight batterie}}{\text{total internal resistance of all the batt}}$$

$$= \frac{8 \times 5}{8 \times 0{\cdot}2} = 25 \text{ A}$$

Therefore, reading of the voltmeter,

$$V = 5 - 25 \times 0{\cdot}2 = 5 - 5 = 0$$

Problem 1.19. (*a*) Three cells of e.m.f. 2·0 V, 1·8 1·5 V are connected in series. Their internal resist are 0·5 Ω, 0·7 Ω and 1 Ω respectively. If the batt connected to an external resistor of 4 Ω via a ver resistance ammeter, what would be the reading i ammeter ?

(*b*) If the three cells above were joined in par would they be characterized by a definite e.m.f internal resistance ? (Independent of external circuit). how will you obtain currents in different branches circuit ? (*Text Que*

Sol. Here, series resistor, R = 4 Ω

(*a*) When cells are joined in series,

net e.m.f. of cells, E = 2·0 + 1·8 + 1·5 = 5·3 V

The total internal resistance of the cells in series,

$$r = 0{\cdot}05 + 0{\cdot}7 + 1 = 1{\cdot}75\ \Omega$$

$$\therefore \quad I = \frac{E}{R+r} = \frac{5{\cdot}3}{4+1{\cdot}75} = \frac{5{\cdot}3}{5{\cdot}75} = \mathbf{0{\cdot}922\ A}$$

(*b*) No, they will not be characterized by a definite e.m.f. and internal resistance. Since there is no formula for total e.m.f. and total internal resistance of non-similar cells, current may be calculated by using Kirchhoff's laws.

FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. What is drift velocity of electrons ? How do you explain the flow of current in a conductor based on this ?
2. What is drift velocity ? Establish the relation between drift velocity and electric current. (*P.S.S.C.E. 2002, 2000, 1999 S, 1999, 1998, 1997, 1996 S ; I.S.C.E. 1997*)
3. Establish the relation between drift velocity of electrons and the electric field applied to the conductor. (*P.S.S.C.E. 2002*)
4. State and explain Ohm's law.
5. Deduce Ohm's law using the concept of drift velocity. (*H.S.S.C.E. 1994*)
6. Is Ohm's law universally applicable to all circuit elements ? Explain. (*Text Question ; Pre-degree Kerala, 1991*)
7. Discuss the various situations, which describe the failure of Ohm's law.
8. Define resistance and give its units. What are the factors on which the resistance of a wire depends ?
9. What are the factors on which the resistance of a conductor depends ? Give the corresponding relation. (*C.B.S.E. 1990*)
10. Define resistivity of a material. Does it depend upon the shape of the cross-section of the wire of the material ? What are its units in cgs and SI system ?
11. A conductor of length l is connected to a d.c. source of potential V. If the length of the conductor is tripled by stretching it, keeping V constant, explain how do the following factors vary in the conductor : (*i*) drift velocity of electrons (*ii*) resistance (*iii*) resistivity. (*C.B.S.E. 2000*)
12. Define resistivity of a conductor. Explain the variation of resistance with temperature in (*a*) metallic conductors and (*b*) semiconductors. (*C.B.S.E. 1999*)
13. Define the term resistivity of a conductor. Give its SI unit. Show that the resistance of a conductor is given by

$$R = \frac{m\,l}{n\,e^2\,\tau\,A},$$

where symbols have their usual meanings. (*C.B.S.E. 2002*)

14. Define relaxation time of electrons in a conductor. Explain how it varies with increase in temperature of a conductor. State the relation between resistivity and relaxation time. (*C.B.S.E. 2001*)
15. Define resistivity and state its SI unit. State and explain how the resistivity of a conductor varies with temperature. (*C.B.S.E. 2001*)
16. Define specific resistance and express it in mass, charge, number density and relaxation time. (*H.S.S.C.E. 2001*)
17. Define the terms : current, ampere, resistance, ohm, resistivity and conductivity.
18. Define conductivity of a conductor. State its SI unit. Explain the variation of conductivity with temperature of a metallic conductor. (*C.B.S.E. 2002*)
19. Define conductivity of a conductor and state its SI unit. State and explain the variation of conductivity of ionic conductor with temperature. (*C.B.S.E. 2001*)
20. Explain the temperature dependence of resistivity in case of a conductor, a semiconductor and insulator.
21. What is a thermistor ? How does it differ from an ordinary resistor ? Explain in brief. List a few applications of a thermistor.
22. What is superconductivity ? Write its applications. (*H.S.S.C.E. 1994*)
23. What are superconductors ? Write their uses. (*P.S.S.C.E. 1995*)
24. Explain the colour code of resistances. (*H.S.S.C.E. 1998, 1995*)
25. How do you connect resistances in series ? Obtain expression for the resistance, when three resistances R_1, R_2 and R_3 are connected in series.
26. Find the total resistance of a circuit, in which three resistances are connected in parallel. (*H.P.S.S.C.E. 1998 S*)
27. Define e.m.f. of a cell. Is it the same as potential difference ? If not, how does it differ from it ?
28. Distinguish between electromotive force and terminal potential difference of a cell. What are their units ? (*H.S.S.C.E. 1998 S*)
29. What is the internal resistance of a cell ? How it can be measured ? (*H.S.S.C.E. 2001*)
30. What do you understand by internal resistance of a cell ? Why does a cell offer internal resistance ? Explain in brief.
31. What is internal resistance of a cell ? Derive an expression for it. (*P.S.S.C.E. 2002, 1999*)
32. Define internal resistance of a cell. Prove that

$$r = \left(\frac{E}{V} - 1\right)R,$$

where R is external resistance used. (*H.P.S.S.C.E. 1999*)

33. When a battery of e.m.f. E and internal resistance r is connected to a resistance R, a current I flows through it. Derive a relation between E, I, r and R. (*C.B.S.E. 1992*)
34. Fig. 1.67 shows a cell with e.m.f. E and internal resistance r, connected to a voltmeter V and a variable resistance R. Deduce the relationship between V, E, R and r. How will the value of V vary, when R is reduced ? (*I.S.C.E. 1998*)

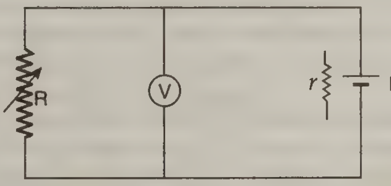

Fig. 1.67

35. Explain, how the cells are grouped in series. Obtain the condition for maximum current through the external resistor.
36. Show with the help of a diagram, how the cells may be connected in parallel. Obtain the condition for the current to be maximum due to a parallel grouping of cells, when connected to an external resistance.

For Practice

Type A. On Definition of current

1. If $2{\cdot}25 \times 10^{20}$ electrons pass through a wire in one minute, find the magnitude of the current flowing through the wire. (*P.S.S.C.E. 2002*) **[Ans.** 0·6 A]
2. How many electrons pass through a lamp in 5 minutes, if the current through it is 0·1 A ? **[Ans.** $1{\cdot}875 \times 10^{20}$]
3. A sulution of sodium chloride discharges $6{\cdot}1 \times 10^{16}$ Na^+ ions and $4{\cdot}6 \times 10^{16}$. Cl^- ions in 2 s. Find the current passing through the solution. **[Ans.** $8{\cdot}56 \times 10^{-3}$ A]
4. An electron moves in a circle of radius 0·15 m with a constant speed of $3{\cdot}6 \times 10^6$ m s^{-1}. What electric current does this correspond to ? **[Ans.** $6{\cdot}1 \times 10^{-13}$ A]
5. The amount of charge passing through the cross-section of a wire in time t is given by

   $$q = a\,t^2 + b\,t + c$$

   (*a*) What are the dimensional formulae of constants a, b, and c ?

   (*b*) If the values of constants a, b, c are 3, 5 and 2 in SI units, find the value of current at $t = 3$ s.

   [Ans. (*a*) $[\mathrm{I\,T^{-1}}]$, [I] and [I T] ; (*b*) 23 A]

Type B. On Drift velocity

6. A current of 5 A is passing through a metallic wire of area of cross-section 4×10^{-6} m^2. If the number density of electrons in the wire is 5×10^{26} m^{-3}, find the drift velocity of electrons. (*Roorkee 1991*) **[Ans.** $1{\cdot}563 \times 10^{-2}$ m s^{-1}]
7. A conductor with a cross-section of 10^{-4} m^2 carries an electric current of 1·2 A. If the number of the free electrons are 5×10^{28} m^{-3}, calculate the electron drift velocity. Charge on the electron, $e = 1{\cdot}6 \times 10^{-6}$ C. **[Ans.** $1{\cdot}5 \times 10^{-6}$ m s^{-1}]
8. A copper wire of diameter 1·0 mm carries a current of 0·2 A. Copper has $8{\cdot}4 \times 10^{28}$ atoms per cubic metre. Find the drift velocity of electrons, assuming that one charge carrier of $1{\cdot}6 \times 10^{-19}$ C is associated with each atom of the metal. (*I.S.C.E. 1997*) **[Ans.** $1{\cdot}895 \times 10^{-5}$ m s^{-1}]
9. A 10 C charge flows through a wire in 5 minutes. The radius of the wire is 1 mm. It contains 5×10^{22} electrons per centimetre^3. Calculate the current and drift velocity. **[Ans.** $3{\cdot}33 \times 10^{-2}$ A, $1{\cdot}325 \times 10^{-6}$ m s^{-1}]
10. What is the drift velocity of electrons in a silver wire of length 1 m, area of cross-section $3{\cdot}14 \times 10^{-6}$ m^2 and carrying a current of 10 A. Given, charge on electron $= 1{\cdot}6 \times 10^{-19}$ C, Avogadro number $= 6{\cdot}02 \times 10^{23}$, atomic weight of silver = 108 and density of silver $= 10{\cdot}5 \times 10^3$ kg m^{-3}. **[Ans.** $3{\cdot}4 \times 10^{-4}$ m s^{-1}]

Type C. On Electron mobility

11. A potential difference of 6 V is applied across a conductor of length 0·12 m. Calculate the drift velocity of electrons, if the electron mobility is $5{\cdot}6 \times 10^{-6}$ m^2 V^{-1} s^{-1}. **[Ans.** $2{\cdot}8 \times 10^{-4}$ m s^{-1}]
12. A current of 1 A flows through a wire of length 0·24 m and area of cross-section 1·2 mm^2, when it is connected to a battery of 3 V. Find the number density of free electrons in the wire, if the electron mobility is $4{\cdot}8 \times 10^{-6}$ m^2 V^{-1} s^{-1}, Given that charge on electron $= 1{\cdot}6 \times 10^{-19}$ C. **[Ans.** $8{\cdot}68 \times 10^{28}$ m^{-3}]

Type D. On Current density

13. A current of 2·4 A flows through a wire of cross-secti
area 1·5 mm^2. Find the current density in the wire. If
wire contains 8×10^{28} free electrons per cubic me
calculate the drift velocity of electrons.
[Ans. $1{\cdot}6 \times 10^6$ A m^{-2} ; $1{\cdot}25 \times 10^{-4}$ m
14. When a potential difference of 1·8 V is applied across a
of length 0·15 m and area of cross-section 0·2 mm
current of 2 A flows through the wire. If the num
density of free electrons in the wire is $6{\cdot}8 \times 10^{28}$
calculate the average relaxation time. Given that charg
electron $= 1{\cdot}6 \times 10^{-19}$ C and mass of electron $= 9{\cdot}1 \times$ 1
kg. **[Ans.** $4{\cdot}36 \times 10$
15. An aluminium wire of diameter 0·24 cm is connecte
series to a copper wire of diameter 0·16 cm. The w
carry an electric current of 10 A. Find (*a*) current densit
free electrons in the aluminium wire and (*b*) drift velo
of electrons in the copper wire. Given that numbe
density of free electrons in copper $= 8{\cdot}4 \times 10^{28}$ m^{-3}.
[Ans. (*a*) $2{\cdot}21 \times 10^6$ A m^{-2} (*b*) $3{\cdot}7 \times 10^{-4}$ m

Type E. On Ohm's law

16. A potential difference of 10 V is applied across a condu
of resistance 1 kΩ. Find the number of electrons flov
through the conductor in 5 minutes. **[Ans.** 1·875 ×1

Type F. On Resistivity

17. A negligibly small current is passed through a wir
length 15 m and uniform cross-section $6{\cdot}0 \times 10^{-7}$ m^2
its resistance is measured to be 5·0 Ω. What is the resisti
of the material at the temperature of the experiment
(*Text Problem*) **[Ans.** 2×10^{-7}
18. The resistance of 100 cm of a thin strip of a metal is fo
to be 2·5 Ω. The cross-section of the strip is a rectang
2 mm × 0·5 mm. Calculate resistivity of the materi
strip. (*Karnataka 1976*)**[Ans.** $2{\cdot}5 \times 10^{-6}$
19. Calculate the resistivity of the material of a wire 2 m l
0·4 mm in diameter and having a resistance of 4 Ω.
(*H.P.S.S.C.E. 1999 S ; P.S.S.C.E. 1*
[Ans. $2{\cdot}513 \times 10^{-7}$
20. A rheostat has 100 turns of a wire of radius 0·4 mm ha
resistivity $4{\cdot}2 \times 10^{-7}$ Ω m. The diameter of each tu
3 cm. What is the maximum value of resistance it
introduce ? **[Ans.** 7·87
21. Given that resistivity of copper is $1{\cdot}68 \times 10^{-8}$
Calculate the amount of copper required to draw a wi
km long having resistance 10 Ω. The density of copp
$8{\cdot}9 \times 10^3$ kg m^{-3}. **[Ans.** 1495·2
22. Find the relaxation time for free electrons in copper, i
density of free electrons is $8{\cdot}4 \times 10^{28}$ m^{-3}. Given
resistivity of copper at room temperature $= 1{\cdot}7 \times 10^{-8}$
mass of electron $= 9{\cdot}1 \times 10^{-31}$ kg and charge on electr
$1{\cdot}6 \times 10^{-19}$ C. **[Ans.** $2{\cdot}49 \times 10$
23. A wire of resistance 2 Ω and resistivity $1{\cdot}1 \times 10^{-6}$ Ω
stretched, so that its length becomes three times o
original length. Determine its new resistance and
resistivity. (*P.S.S.C.E. 1999 S*) **[Ans.** 18 Ω ; unchang

24. A wire has a resistance of 32 Ω. It is melted and drawn into a wire of half of its original length. Calculate the resistance of the new wire. What is the percentage change in resistance ? *(C.B.S.E. 1997)* **[Ans.** 75% (decrease)**]**

25. A wire of stretched by 20%. What is percentage change in its resistance ? **[Ans.** 44%**]**

26. A wire is of resistance R is stretched, so that its radius decreases by factor n. Calculate its new resistance. **[Ans.** n^4 R**]**

27. A wire of uniform cross-section has a resistance of 9 Ω. It is cut into three equal pieces. Each piece is stretched uniformly to three times its length and all the three stretched pieces are connected in parallel. Assuming that stretching of wires does not cause any change in density of their material, calculate total resistance of the combination described. *(C.B.S.E. 1997)* **[Ans.** 9 Ω**]**

28. Two wires is the same material having lengths in the ratio 1 : 2 and diameters in the ratio 2 : 3 are connected in series with an accumulator. Compute the ratio of potential differences across the two wires. *(H.S.S.C .E. 2000)* **[Ans.** 9 : 8**]**

29. A uniform copper wire of mass $2{\cdot}23 \times 10^{-3}$ kg carries a current of 1 A, when a potential difference of 1·7 V is applied across it. Calculate the length and area of cross-section of the wire. If the wire is uniformly stretched to double its length, calculate the new resistance. Given that density of copper is $8{\cdot}92 \times 10^3$ kg m^{-3} and resistivity is $1{\cdot}7 \times 10^{-8}$ Ω m. *(Roorkee 1995)* **[Ans.** 5 m ; 5×10^{-8} m^2 ; 6·8 Ω**]**

pe G. On Conductivity

30. Calculate the conductivity of a wire of length 200 cm, area of cross-section 2 cm^2 and of resistance 5×10^{-4} Ω. *(P.S.S.C.E. 1999)* **[Ans.** 2×10^{-7} S m^{-1}**]**

31. Calculate the conductance and conductivity of a wire of resistance 0·01 Ω, area of cross-section 10^{-4} m^2 and length 0·1 m. *(H.S.S.C.E. 2000, 1999 S)* **[Ans.** 100 S ; 10^5 S m^{-1}**]**

32. Calculate the electric field in a copper wire of cross-sectional area 2·0 mm^2 carrying a current of 1 A. The conductivity of copper = $6{\cdot}25 \times 10^7$ S m^{-1}. **[Ans.** 8×10^{-3} V m^{-1}**]**

pe H. On Variation of resistance with temperature

33. A wire has a resistance of 10·5 Ω at 21°C and 16·4 Ω at 147°C. Find the value of coefficient of resistance. **[Ans.** $4{\cdot}46 \times 10^{-3}$ K^{-1}**]**

34. At room temperature (27·0°C) , the resistance of a heating element is 100 Ω. What is the temperature of the element, if the resistance is found to be 117 Ω ? Given that the temperature coefficient of the material of the resistor is $1{\cdot}70 \times 10^{-4}$ °C^{-1}. *(Text Problem)* **[Ans.** 1027 °C**]**

35. The resistance of a tungsten filament at 150 °C is 133 Ω. What will be its resistance at 500 °C ? The temperature coefficient of resistance of tungsten at 0 °C is 0·0045 °C^{-1}. **[Ans.** 258 Ω**]**

pe I. On Colour code of Carbon resistance

36. The colour code of a carbon resistance is as shown in Fig. 1.68. What is the value of this resistance ? *(H.S.S.C.E. 2001]* **[Ans.** 24×10^7 Ω ± 10%**]**

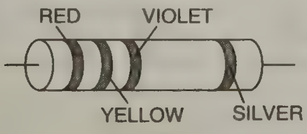

Fig. 1.68

37. A carbon resistor has three colours blue, yellow and red respectively. What will be the resistance ? *(H.S.S.C.E. 2000, 1998)* **[Ans.** 64×10^2 Ω**]**

38. A carbon resistor is marked in coloured bands of red, black, orange and silver. What is the resistance and tolerance value of the resistor ? *(C.B.S.E. 2002)* **[Ans.** 20×10^3 Ω ± 10%**]**

39. A carbon resistor is marked in coloured bands in the sequence blue, green, orange and gold. What is the resistance and tolerance value of the resistor ? *(C.B.S.E. 2002)* **[Ans.** 65×10^3 Ω + 5%**]**

40. A voltage of 200 V is applied across a colour coded carbon resistor with first, second and third rings of blue, black and yellow colours. What is the current flowing through the resistor ? *(H.S.S.C.E. 1999)* **[Ans.** $3{\cdot}33 \times 10^{-4}$ A**]**

41. Draw the colour code scheme of 42 kΩ + 10% carbon resistance. *(H.S.S.C.E. 1998 S)* **[Ans.** Yellow, red, orange and silver**]**

TYPE J. On series and parallel combination of resistances

42. The total resistance of two resistors, when connected in series is 9 Ω and when connected in parallel, their total resistance becomes 2 Ω. Find the value of each resistance. *(P.S.S.C.E. 2000)* **[Ans.** 6 Ω , 3 Ω**]**

43. Two resistances are in the ratio 1 : 4. If these are connected in parallel, their total resistance becomes 20 Ω. Find the value of each resistance. *(P.S.S.C.E. 2000)* **[Ans.** 25 Ω,100 Ω**]**

44. A parallel combination of three resistors takes a current of 5 A from a 20 V supply. If the two resistors are of 10 ohm and 8 ohm, final the value of third one. *(P.S.S.C.E. 1999)* **[Ans.** 40 Ω**]**

45. A parallel combination of three resistors takes a current of 7·5 A from a 30 V supply. If the two resistors are 10 ohm and 12 Ω, find the third one. *(P.S.S.C.E. 1999)* **[Ans.** 15 Ω**]**

46. Three resistances are connected to form the sides of a triangle ABC [Fig. 1.69]. The resistance of the side AB is 40 Ω, of the side BC 60 Ω and of the side CA 100 Ω. Calculate the effective resistance between the points A and B. *(I.I.T. 1975)* **[Ans.** 32 Ω**]**

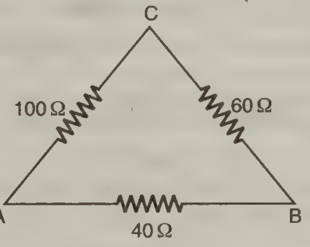

Fig. 1.69

47. The letter A is constructed with resistance wires of resistance 1 Ω each as shown in Fig. 1.70. Find the effective resistance between the points M and N. **[Ans.** 2·67 Ω**]**

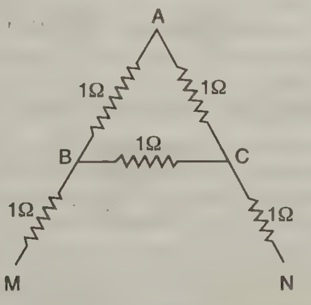

Fig. 1.70

48. The letter A is connected from a uniform wire of resistance 1 Ω cm^{-1}. The sides of the letter are each 20 cm long and cross-piece in the middle is 10 cm long, while the apex angle is 60°. Find the resistance of the letter between two ends of the legs. *(H.P.S.S.C.E. 1998)* **[Ans.** 26·67 Ω**]**

49. The letter A consists of a uniform wire of resistance 1 Ω cm^{-1}. The sides of the letter are 40 cm long and the crosspiece 10 cm long divides the sides in the ratio 1 : 3 from the apex. Find the resistance of the letter between the two ends of the legs. *(P.S.S.C.E. 1998 S)* **[Ans.** 66·67 Ω**]**

50. Calculate the equivalent resistance of the network shown in Fig. 1.71 between points A and B. **[Ans.** 12·73 Ω**]**

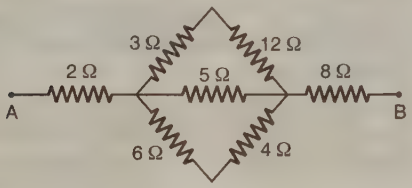

Fig. 1.71

51. What is the net resistance between points A and B in the circuit shown in Fig. 1.72 ? *(P.S.S.C.E. 1993)* **[Ans.** 5 Ω**]**

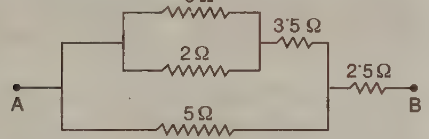

Fig. 1.72

52. Calculate the equivalent resistance of the network shown in Fig. 1.73 between points A and B. **[Ans.** 8 Ω**]**

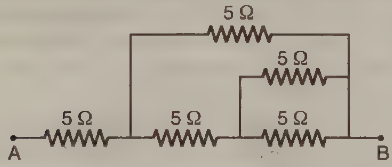

Fig. 1.73

53. Find the equivalent resistance of the network shown in Fig. 1.74 between points A and B. **[Ans.** 4·8 Ω**]**

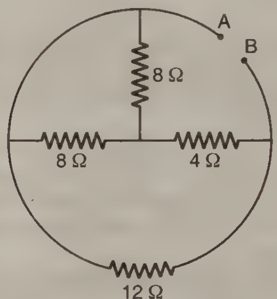

Fig. 1.74

54. Find the equivalent resistance of the network shown in 1.75 between points A and B. **[Ans.** 2·

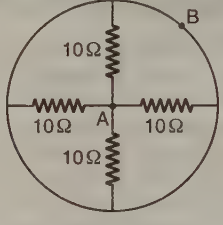

Fig. 1.75

55. Find the charge on the capacitor shown in Fig. 1.76. **[Ans.** 10

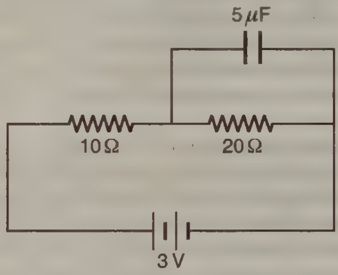

Fig. 1.76

56. Find the potential difference ($V_A - V_B$) between point and B in the network shown in Fig. 1.77. **[Ans.** 1

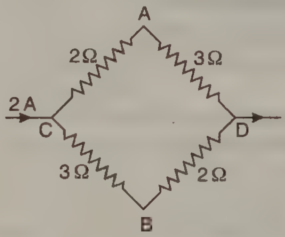

Fig. 1.77

57. Determine the total resistance in the circuit as show Fig. 1.78. Also determine the current in each resistor potential drop it. **[Ans.** 5 Ω, 10 A through 12 Ω, 2 through 6 Ω, 30 A through 4 Ω, 180 V across 3 Ω 120 V across each of 12, 6 and 4 Ω resist

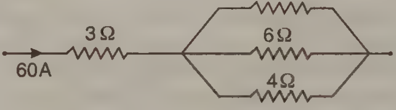

Fig. 1.78

58. In the circuit shown in Fig. 1.79, $R_1 = 100\ \Omega$, $R_2 = R_3 =$ Ω, $R_4 = 75\ \Omega$ and the battery is of e.m.f., E = 4·75 V. F the equivalent resistance of the circuit and current pass through the each resistor.

[Ans. 118·75 Ω ; $I(R_1) = 0{\cdot}04$ A ; $I(R_2) = 0{\cdot}015$
$I(R_3) = 0{\cdot}015$ A, $I(R_4) = 0{\cdot}0$

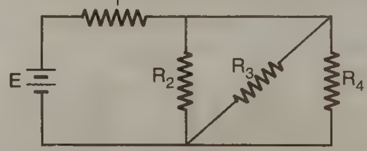

Fig. 1.79

9. Find the resistance of the network between (*a*) points A and B (*b*) points A and C shown in Fig. 1.80.
[Ans. (*a*) 27·5 Ω (*b*) 30 Ω]

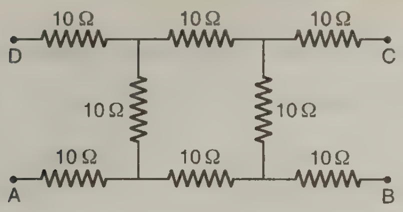

Fig. 1.80

0. Calculate the current shown by the ammeter A in the circuit diagram given in Fig. 1.81. (*C.B.S.E. 2000*)
[Ans. 3·6 A]

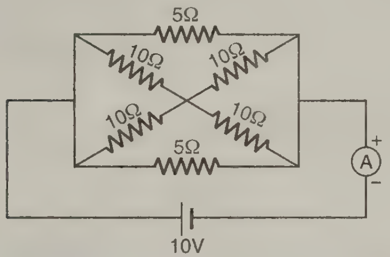

Fig. 1.81

e K. On Internal resistance of a cell

1. The e.m.f. of a cell is 1·5 V. On connecting a 14 Ω resistance across the cell, the terminal potential difference falls to 1·4 V. Calculate the internal resistance of the cell. (*H.S.S.C.E. 2001*) **[Ans.** 1 Ω]

2. Two poles of a cell of e.m.f. 1·5 V are connected to the ends of a 10 Ω coil. If the current in the circuit is 0·1 A, calculate the internal resistance of the coil. (*Karnataka, 1983 S*)
[Ans. 5 Ω]

3. The e.m.f. of Daniel cell is 1·09 V and internal resistance is 2 Ω. If the terminals of the cell are joined by a wire of resistance 18 Ω, find the potential difference recorded by a high resistance voltmeter also connected to the terminals of the cell. **[Ans.** 0·981 V]

4. In the circuit, shown in Fig. 1.82, the voltmeter reads 1·5 V, when the key is open. When the key is closed, the voltmeter reads 1·35 V and ammeter reads 1·5 A. Find the external resistance R and the internal resistance of the cell.
[Ans. 0·9 Ω ; 0·1 Ω]

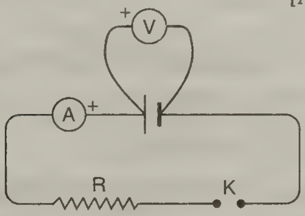

Fig. 1.82

5. If a battery of e.m.f. 6·6 V can supply a current of 3 A through a resistance of 1·8 Ω, what current does it supply through another resistance of 2·9 Ω. Also calculate internal resistance of the battery. **[Ans.** 2 A, 0·4 Ω]

6. Two resistances of 6 Ω and 12 Ω are connected in parallel. Their terminals are connected to a battery of e.m.f. 4·8 V and internal resistance of 2 Ω. Find the current supplied by the battery and the current through each resistance.
[Ans. 0·8 A, 0·533 A, 0·267 A]

7. A cell of e.m.f. 1·5 V and internal resistance 1 Ω sends a current through wires of resistance 6 Ω and 12 Ω connected in parallel. Find the current through each wire.
[Ans. 0·2 A, 0·1 A]

68. The potential difference across the terminals of a battery is 8·5 V, when a current of 3 A flows through it from its negative terminal to the positive terminal. When a current of 2 A flows through it in the opposite direction, the terminal potential difference is 11 V. Find the internal resistance of the battery and its e.m.f. **[Ans.** 0·5 Ω, 10 V]

69. The potential difference across the terminals of a 3 V battery is 3·6 V, when it is being charged by a current of 1·5 A. What is the internal resitance of the battery ?
[Ans. 0·4 Ω]

70. Find the magnitude of the current supplied by the battery in the circuit shown in Fig. 1.83. Also find the potential difference between the points P and Q. **[Ans.** 1 A, 1·5 V]

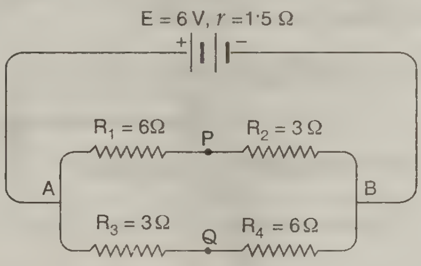

Fig. 1.83

Type L. On Grouping of cells

71. A galvanometer together with an unknown resistance in series is connected across two identical batteries each of 1·5 V. When the batteries are connected in series, the galvanometer records a current of 1 A and when the batteries are in parallel, the current is 0·6 A. What is the internal resistance of the battery ? (*I.I.T. 1973*)
[Ans. 1/3 Ω]

72. Two identical cells, each of e.m.f. 2 V are connected in parallel. This combination is connected to a 5 Ω resistor. If the terminal voltage across the cells in the closed circuit is 1·5 V, calculate the internal resistance of each cell.
(*C.B.S.E. 1998 S*) **[Ans.** 3·33 Ω]

73. Two identical cells of e.m.f. 1·5 V each joined in parallel provide supply to an external circuit consisting of two resistors of 17 Ω each joined in parallel. A very high resistance voltmeter reads the terminal voltage of the cells to be 1·4 V. What is the internal resistance of each cell ?
(*Text Problem*) **[Ans.** 1·214 Ω]

74. Three identical cells, each of e.m.f. 2 V and unknown internal resistance are connected in parallel. This combination is connected to a 5 ohm resistor. If the terminal voltage across the cell is 1·5 volt, what is the internal resistance of each cell. (*C.B.S.E. 1999*)
[Ans. 5 Ω]

75. Two cells each of e.m.f. 1·1 V and internal resistance 2 Ω are joined in parallel with a resistance of 10 Ω. Find the current through the resistance and through each cell.
[Ans. 0·1 A, 0·05 A]

MISCELLANEOUS PROBLEMS

76. The earth's surface has a negative surface charge density of 10^{-9} C m^{-2}. The potential difference of 400 kV between the top of the atmosphere and the surface results (due to low conductivity of the lower atmosphere) in a current of only 1800 A over the entire globe. If there were no mechanism of substaining atmospheric electric field ; how much time would be required to neutralise the earth's surface ? (This never happens in practice, because there is

a mechanism to replenish electric charges namely the continual thunder storms and lightning in different parts of the globe). Radius of the earth = $6{\cdot}37 \times 10^6$ m.

(*Text Problem*) [**Ans.** 283·3 s]

77. Find the equivalent resistance of the network shown in Fig. 1.84 between points A and B, when (*a*) the key K is open and (*b*) the key K is closed. [**Ans.** (*a*) 2·5 Ω (*b*) 2·4 Ω]

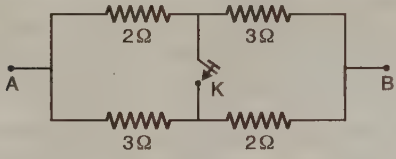

Fig. 1.84

78. In the circuit shown in Fig. 1.85, determine the potential difference across the capacitor. [**Ans.** 12 V]

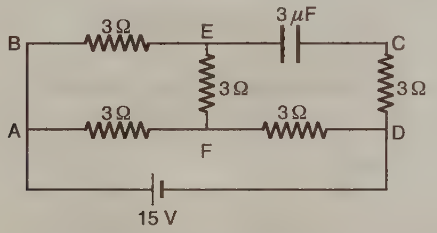

Fig. 1.85

79. In the circuit shown in Fig. 1.86, find the pote difference between points A and B. Given that E_1 = $E_2 = 8$ V, $R_1 = 3\ \Omega$ and $R_2 = 1\ \Omega$ [**Ans.**

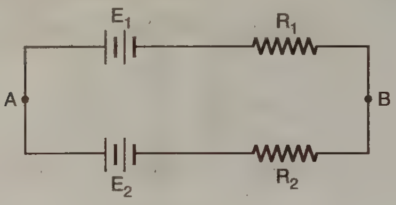

Fig. 1.86

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. $$I = \frac{ne}{t} = \frac{2{\cdot}25 \times 10^{20} \times 1{\cdot}6 \times 10^{-19}}{60} = \mathbf{0{\cdot}6\ A}$$

2. Proceed as in solved problem no. 1.01.

3. $$I = \frac{(n^+ + n^-) \times e}{t}$$
$$= \frac{(6{\cdot}1 \times 10^{16} + 4{\cdot}6 \times 10^{16}) \times 1{\cdot}6 \times 10^{-19}}{2}$$
$$= \mathbf{8{\cdot}56 \times 10^{-3}\ A}$$

4. The electron crosses a point on the circle once in every revolution. If v is number of revolutions made by the electron in 1 s, then its motion along circle corresponds to a current,

$$I = e\,v = e \times \frac{1}{T} = \frac{e}{2\pi r / v} = \frac{e\,v}{2\pi r}$$
$$= \frac{1{\cdot}6 \times 10^{-19} \times 3{\cdot}6 \times 10^6}{2\pi \times 0{\cdot}15} = \mathbf{6{\cdot}1 \times 10^{-13}\ A}$$

5. Here, $q = a\,t^2 + b\,t + c$

(*a*) Dimensions of each factor on R.H.S. of the above relation are that of charge *i.e.* current × time or [I T].

$$\therefore [a] = \left[\frac{q}{t^2}\right] = \frac{[\text{I T}]}{[\text{T}^2]} = [\text{I T}^{-1}],\ [b] = \left[\frac{q}{t}\right] = \frac{[\text{I T}]}{[\text{T}]} = [\text{I}]$$

and $[c] = [q] = [\text{I T}]$

(*b*) Here, $a = 3$, $b = 5$ and $c = 2$

Now, $I = \dfrac{dq}{dt} = \dfrac{d}{dt}(a\,t^2 + b\,t + c) = 2\,a\,t + b$

$\therefore$ I (at $t = 3$ s) $= 2 \times 3 \times 3 + 5 =$ **23 A**

6. Proceed as in solved problem no. 1.03,

7. Proceed as in solved problem no. 1.03

8. Diameter of wire, D = 1·0 mm = 10^{-3} m

Therefore, area of cross-section of wire,

$$A = \frac{\pi D^2}{4} = \frac{\pi \times (10^{-3})^2}{4} = 7{\cdot}854 \times 10^{-7}\ \text{m}^2$$

Now, proceed as in solved problem no. 1.03

9. Proceed as in problem no. 8.

10. Mass of silver wire,

$$m = A \times l \times \rho = 3{\cdot}14 \times 10^{-6} \times 1 \times 10{\cdot}5 \times 10^3$$
$$= 3{\cdot}297 \times 10^{-2}\ \text{kg} = 32{\cdot}97\ \text{g}$$

Therefore, number of atoms in silver wire

$$= \frac{6{\cdot}02 \times 10^{23}}{108} \times 32{\cdot}97 = 1{\cdot}838 \times 10^{23}$$

Volume of wire = A l = 1× $3{\cdot}14 \times 10^{-6} = 3{\cdot}14 \times 10^{-6}$ m

Assuming that there is one free electron correspondi each silver atom, number of electrons per unit volur the silver wire,

$$n = \frac{1{\cdot}838 \times 10^{23}}{3{\cdot}14 \times 10^{-6}} = 5{\cdot}854 \times 10^{28}\ \text{m}^{-3}$$

Now, $v_d = \dfrac{I}{n\,e\,A}$

$$= \frac{10}{5{\cdot}854 \times 10^{28} \times 1{\cdot}6 \times 10^{-19} \times 3{\cdot}14 \times 10^{-6}}$$
$$= \mathbf{3{\cdot}4 \times 10^{-4}\ m\ s^{-1}}$$

11. $$E = \frac{V}{l} = \frac{6}{0{\cdot}12} = 50\ \text{V m}^{-1}$$

Now, $v_d = \mu\,E = 5{\cdot}6 \times 10^{-6} \times 50 = \mathbf{2{\cdot}8 \times 10^{-4}\ m\ s^{-1}}$

12. $$E = \frac{V}{l} = \frac{3}{0{\cdot}24} = 12{\cdot}5\ \text{V m}^{-1}$$

Now, $v_d = \mu\,E = 4{\cdot}8 \times 10^{-6} \times 12{\cdot}5 = 6 \times 10^{-5}\ \text{m s}^{-1}$

Also, $v_d = \dfrac{I}{n\,A\,e}$ or $n = \dfrac{I}{A\,e\,v_d}$

or $$n = \frac{1}{1{\cdot}2 \times 10^{-6} \times 1{\cdot}6 \times 10^{-19} \times 6 \times 10^{-5}}$$
$$= \mathbf{8{\cdot}68 \times 10^{28}\ m^{-3}}$$

13. $$j = \frac{I}{A} = \frac{2{\cdot}4}{1{\cdot}5 \times 10^{-6}} = \mathbf{1{\cdot}6 \times 10^6\ A\ m^{-2}}$$

Now, $v_d = \dfrac{j}{ne} = \dfrac{1\cdot6\times10^{6}}{8\times10^{28}\times1\cdot6\times10^{-19}}$

$= \mathbf{1{\cdot}25 \times 10^{-4}\ m\ s^{-1}}$

14. Proceed as in solved problem no. 1.09.

15. (*a*) Area of cross-section of aluminium wire,

$$A = \frac{\pi D^2}{A} = \frac{\pi\times(0\cdot24)^2}{4} = 4{\cdot}524\times10^{-2}\ \text{cm}^2$$

$$= 4{\cdot}524\times10^{-6}\ \text{m}^2$$

Now, $j = \dfrac{I}{A} = \dfrac{10}{4\cdot524\times10^{-6}} = \mathbf{2{\cdot}21\times10^{6}\ A\ m^{-2}}$

(*b*) Area of cross-section of copper wire,

$$A = \frac{\pi D^2}{4} = \frac{\pi\times(0\cdot16)^2}{4} = 2{\cdot}01\times10^{-2}\ \text{cm}^2$$

$$= 2{\cdot}01\times10^{-6}\ \text{m}^2$$

Now, $v_d = \dfrac{I}{neA}$

$$= \frac{10}{8\cdot4\times10^{28}\times1\cdot6\times10^{-19}\times2\cdot01\times10^{-6}}$$

$= \mathbf{3{\cdot}7\times10^{-4}\ m\ s^{-1}}$

16. $I = \dfrac{V}{R} = \dfrac{10}{10^3} = 10^{-2}\ \text{A}$

Now, $q = I\,t$ or $n\,e = I\,t$

or $n = \dfrac{I\,t}{e} = \dfrac{10^{-2}\times5\times60}{1\cdot6\times10^{-19}} = \mathbf{1{\cdot}875\times10^{19}}$

17. Proceed as in solved problem no. 1.11.

18. Proceed as in solved problem no. 1.11.

19. Proceed as in solved problem no. 1.11.

20. Number of turns of rheostat wire, $n = 100$

Diameter of a turn of rheostat wire,

$$D = 3\ \text{cm} = 0{\cdot}03\ \text{m}$$

Therefore, length of rheostat wire,

$$l = n \times \text{circumference of one turn} = n\times\pi D$$
$$= 100\times\pi\times0{\cdot}03\ \text{m}$$

Area of cross-section of wire,

$$A = \pi r^2 = \pi\times(0{\cdot}4\times10^{-3})^2\ \text{m}^2$$

Therefore, maximum resistance, which rheostat can introduce,

$$R = \rho\frac{l}{A} = \frac{4\cdot2\times10^{-7}\times100\times\pi\times0\cdot03}{\pi\times(0\cdot4\times10^{-3})^2} = \mathbf{7{\cdot}875\ \Omega}$$

21. Now, $R = \rho\dfrac{l}{A}$ or $A = \rho\dfrac{l}{R}$

or $A = \dfrac{1\cdot68\times10^{-8}\times10\times10^{3}}{10} = 1\cdot68\times10^{-5}\ \text{m}^2$

Mass of copper required, m = volume × density

or $m = A\,l\times\text{density}$

$= 1{\cdot}68\times10^{-5}\times10\times10^{3}\times8{\cdot}9\times10^{3} = \mathbf{1495{\cdot}2\ kg}$

22. Now, $\rho = \dfrac{m}{ne^2\tau}$ or $\tau = \dfrac{m}{ne^2\rho}$

or $\tau = \dfrac{9\cdot1\times10^{-31}}{8\cdot4\times10^{28}\times(1\cdot6\times10^{-19})^2\times1\cdot7\times10^{-8}}$

$= \mathbf{2{\cdot}49\times10^{-14}\ s}$

23. Proceed as in solved problem no. 1.13.

The resistivity of wire will remain unchanged, as it depends on the nature of material of the wire only.

24. Proceed as in solved problem no. 1.13.

25. Proceed as in solved problem no. 1.13.

26. Now, $R = \rho\dfrac{l}{\pi r^2}$ ...(*i*)

When radius is decreased by a factor n, new resistance of the wire

$$R' = \rho\frac{l'}{\pi(r/n)^2} \qquad ...(ii)$$

As the volume of wire must remain the same,

$$l\times\pi r^2 = l'\times\pi\left(\frac{r}{n}\right)^2 \quad \text{or} \quad l' = n^2 l$$

Substituting for l' in equation (*ii*), we have

$$R' = \rho\frac{n^2 l}{\pi(r/n)^2} = n^4\times\rho\frac{l}{\pi r^2} = \mathbf{n^4 R}$$

27. Resistance of each piece of the wire, $R = \dfrac{9}{3} = 3\,\Omega$

Let l be length and A, the area of cross-section of each piece of the wire. Then,

$$\rho\frac{l}{A} = 3 \qquad ...(i)$$

When wire is stretched to three times to length *i.e.* $3\,l$, its area will decrease to A/3. Therefore,
new resistance of a piece of wire,

$$R' = \rho\frac{3l}{A/3} = 9\times\rho\frac{l}{A} = 9\times3 = 27\,\Omega$$

Let R_p' be the equivalent resistance, when all the three pieces are connected in paralle. Then,

$$\frac{1}{R_p'} = \frac{1}{27}+\frac{1}{27}+\frac{1}{27} = \frac{1}{9} \quad \text{or} \quad R_p' = 9\,\Omega$$

28. Let l and $2\,l$ be length of the two wires and 2 D and 3 D be their diameters. If ρ is resistivity of their material, then

$$R_1 = \rho\frac{l}{\pi(2D)^2/4} = \frac{\rho l}{\pi D^2}$$

and $R_2 = \rho\dfrac{2l}{\pi(3D)^2/4} = \dfrac{8\rho l}{9\pi D^2}$

As the two wires are connected in series with an accumulator, same current will flow through the two wires. Hence, potential difference across the two wires will be proportional to their resistances. Thus,

$$\frac{V_1}{V_2} = \frac{R_1}{R_2} = \mathbf{\frac{9}{8}}$$

29. Now, $R = \rho\dfrac{l}{A}$ or $\dfrac{V}{I} = \rho\dfrac{l}{A}$

or $\dfrac{l}{A} = \dfrac{V}{I\rho} = \dfrac{1\cdot7}{1\times1\cdot7\times10^{-8}} = 10^{8}$ ...(*i*)

Also, mass of wire = volume × density

or $2{\cdot}23\times10^{-3} = A\,l\times8{\cdot}92\times10^{3}$

or $A\,l = \dfrac{2\cdot23\times10^{-3}}{8\cdot92\times10^{3}} = 2\cdot5\times10^{-7}$ ...(*ii*)

Solving equations (*i*) and (*ii*), we get,

$$l = 5\ \text{m} \quad \text{and} \quad \mathbf{A = 5\times10^{-8}\ m^2}$$

When the wire is stretched to double its length, it can be found that its resistance will become four times.
Therefore, new resistance,

$$R' = \left(\frac{V}{I}\right)\times4 = \frac{1\cdot7}{1}\times4 = \mathbf{6{\cdot}8\ \Omega}$$

30. Proceed as in solved problem no. 1.14.

31. Conductance, $G = \dfrac{1}{R} = \dfrac{1}{0\cdot01} = \mathbf{100\ S}$

For finding conductivity, proceed as in solved problem 1.14.

32. Now, $\rho=\frac{1}{\sigma}=\frac{1}{6\cdot25\times10^{7}}=1\cdot6\times10^{-8}\ \Omega\,\text{m}$

∴ $R=\rho\frac{l}{A}=\frac{1\cdot6\times10^{-8}\times l}{2\cdot0\times10^{-6}}=8\times10^{-3}\,l$

Now, $V=IR=1\times8\times10^{-3}\,l=8\times10^{-3}\,l$

Hence, $E=\frac{V}{l}=\mathbf{8\times10^{-3}\ V\,m^{-1}}$

33. Proceed as in solved problem no. 1.16.

34. Now, $R_2=R_1\,[1+\alpha\,(\theta_2-\theta_1)]$

or $117=100\,[1+1{\cdot}7\times10^{-4}\,(\theta_2-27)]$

or $\theta_2=\frac{117-100}{100\times1\cdot7\times10^{-4}}+27=\mathbf{1027\ ^\circ C}$

35. Now, $R_\theta=R_0\,(1+\alpha\,\theta)$

∴ $R_{150}=R_0\,(1+0{\cdot}0045\times150)$ ...(*i*)

and $R_{500}=R_0\,(1+0{\cdot}0045\times500)$ ...(*ii*)

From equations (*i*) and (*ii*), we have

$$R_{500}=R_{150}\times\frac{1+0\cdot0045\times500}{1+0\cdot0045\times150}=258\ \Omega$$

36. Proceed as in solved problem no. 1.19.

37. Proceed as in solved problem no. 1.19.

38. Proceed as in solved problem no. 1.19.

39. Proceed as in solved problem no. 1.19.

40. To find R, proceed as in solved problem no. 1.19 and then find current through the resistor.

41. Proceed as in solved problem no. 1.20.

42. Proceed as in solved problem no. 1.23.

43. Let R and 4 R be the values of two resistances.

Now, $R_p=\frac{R\times4R}{R+4R}$ or $20=0{\cdot}8\,R$

or $\mathbf{R=25\ \Omega}$ and $4\,R=4\times25=\mathbf{100\ \Omega}$

44. Now, $R_p=\frac{20}{5}=4\,\Omega$

Let R be the unknown resistance. Then,

$\frac{1}{4}=\frac{1}{R}+\frac{1}{10}+\frac{1}{8}$ or $\frac{1}{R}=\frac{1}{4}-\frac{1}{10}-\frac{1}{8}=\frac{1}{40}$

or $\mathbf{R=40\ \Omega}$

45. Proceed as in problem no. 44.

46. Let $R_1=40\ \Omega$, $R_2=60\ \Omega$ and $R_3=100\ \Omega$

Between points A and B, a series combination of R_2 and R_3 is connected in parallel to R_1. Let R_s be resistance of series combination of R_2 and R_3. Then,

$R_s=R_2+R_3=60+100=160\ \Omega$

Hence, the equivalent resistance between points A and B,

$$R=\frac{R_s\times R_1}{R_s+R_1}=\frac{160\times40}{160+40}=32\ \Omega$$

47. By proceeding as in problem 46, find the resistance R′ of the triangular part ABC. It can be obtained that

$R'=0{\cdot}67\ \Omega$

Hence, resistance between points M and N,

$R=1+R'+1=1+0{\cdot}67+1=\mathbf{2{\cdot}67\ \Omega}$

48. Refer to Fig. 1.70. Since apex angle is 60°, Δ ABC is an equilateral triangle *i.e.* AB = BC = AC = 10 cm.

Also, BM = CN = 20 − 10 = 10 cm

Further, as the wire has resistance of 1 Ω cm^{-1}, the resistance of each of the parts AB, BC, AC, BM and CN is 10 Ω.

Now, proceed as in problem no. 47 to find the effective resistance of the letter between two ends of the legs.

49. Refer to Fig 1.70. Since cross-piece divides the sides of the letter in the ratio 1 : 3,

AB = AC = 10 cm and BM = CN = 30 cm

Since the wire has resistance of 1 Ω cm^{-1}, the resistanc of the parts AB, BC, AC, BM and CN are 10 Ω, 10 10 Ω, 30 Ω and 30 Ω respectively.

Now, proceed as in problem no. 47 to find the resistanc of the letter between the two ends of the legs.

50. Let R_1 be resistance of the series combination of 3 Ω an 12 Ω resistances and R_2 that of 6 Ω and 4 Ω resistances.

Then, $R_1=3+12=15\ \Omega$ and $R_2=6+4=10\ \Omega$

If R_p is resistance of parallel combination of R_1, R_2 an 5 Ω resistance, then

$$\frac{1}{R_p}=\frac{1}{R_1}+\frac{1}{R_2}+\frac{1}{5}=\frac{1}{15}+\frac{1}{10}+\frac{1}{5}=\frac{11}{30}$$

or $R_p=\frac{30}{11}=2\cdot73\,\Omega$

Therefore, equivalent resistance of network between points A and B,

$R=2+R_p+8=2+2{\cdot}73+8=\mathbf{12{\cdot}73\ \Omega}$

51. The given network is equivalent to the network shown i Fig. 1.87 :

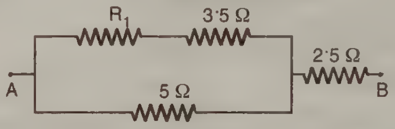

Fig. 1.87

Since R_1 is resistance of the parallel combination o resistors of 6 Ω and 2 Ω,

$$R_1=\frac{6\times2}{6+2}=1\cdot5\,\Omega$$

The network shown above is now equivalent to the network shown in Fig. 1.88 :

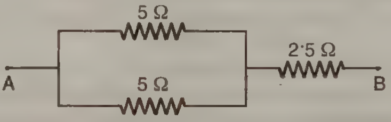

Fig. 1.88

Therefore, net resistance between points A and B,

$$R=\frac{5\times5}{5+5}+2\cdot5=2\cdot5+2\cdot5=5\,\Omega$$

52. The given network is equivalent to the network shown i Fig. 1.89 :

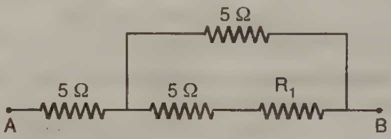

Fig. 1.89

Since R_1 is resistance of the parallel combination of tw resistors of 5 Ω each,

$$R_1=\frac{5\times5}{5+5}=2\cdot5\,\Omega$$

The network shown above is now equivalent to the network shown in Fig. 1.90 :

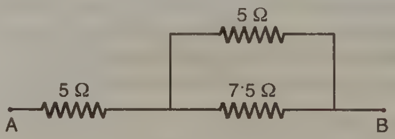

Fig. 1.90

Therefore, equivalent resistance of the network between points A and B,

$$R = 5 + \frac{5 \times 7 \cdot 5}{5 + 7 \cdot 5} = 8\ \Omega$$

53. The given network is equivalent to the network shown in Fig. 1.91 :

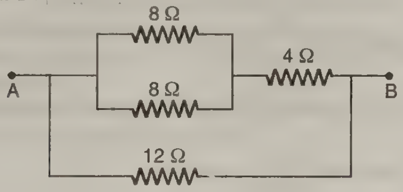

Fig. 1.91

By proceeding as in problem no. 51, it can be obtained that equivalent resistance of the network is **4·8 Ω**.

54. The given network is equivalent to the network shown in Fig. 1.92 :

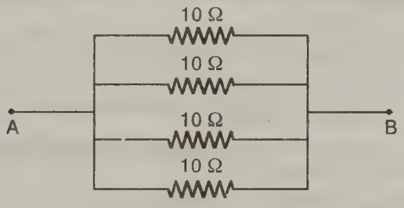

Fig. 1.92

Therefore, equivalent resistance of the network between points A and B is given by

$$\frac{1}{R} = \frac{1}{10} + \frac{1}{10} + \frac{1}{10} + \frac{1}{10} = \frac{4}{10} \quad \text{or} \quad R = \mathbf{2{\cdot}5\ \Omega}$$

55. Current in the circuit, $I = \dfrac{3}{10 + 20} = 0 \cdot 1\ A$

Potential difference across 20 Ω resistor,

$V = 20 \times 0{\cdot}1 = 2\ V$

Therefore, charge on capacitor,

$q = C\,V = 5 \times 2 = \mathbf{10\ \mu C}$

56. The resistance of both the branches CAD and CBD of the circuit is same *i.e.* equal to 5 Ω. Therefore, current of 2 A at point C will divide equally through the two branches.

Hence, $V_C - V_A = 2 \times 1 = 2\ V$

and $V_C - V_B = 3 \times 1 = 3\ V$

Now, $V_A - V_B = (V_C - V_B) - (V_C - V_A) = 3 - 2 = \mathbf{1\ V}$

57. Let R_p be resistance of the parallel combination of 12 Ω, 6 Ω and 4 Ω resistors. Then,

$$\frac{1}{R_p} = \frac{1}{12} + \frac{1}{6} + \frac{1}{4} = \frac{1}{2} \quad \text{or} \quad R_p = 2\ \Omega$$

Therefore, total resistance of the given circuit,

$R = 3 + R_p = 3 + 2 = 5\ \Omega$

Potential drop across 3 Ω resistor = 3 × 60 = **180 V**

Potential drop across the parallel combination of resistors of 12 Ω, 6 Ω and 4 Ω

$= R_p \times 60 = 2 \times 60 = 120\ V$

Therefore, potential drop across each of the three resistors (*i.e.* 12 Ω, 6 Ω and 4 Ω) is **120 V**.

Current through 12 Ω resistor $= \dfrac{120}{12} = \mathbf{10\ A}$,

current through 6 Ω resistor $= \dfrac{120}{6} = \mathbf{20\ A}$

and current through 4 Ω resistor $= \dfrac{120}{4} = \mathbf{30\ A}$

58. The resistors R_2, R_3 and R_4 are in parallel. Their effective resistance is given by

$$\frac{1}{R_p} = \frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4} = \frac{1}{50} + \frac{1}{50} + \frac{1}{75} = \frac{8}{150}$$

or $R_p = 18{\cdot}75\ \Omega$

Therefore, equivalent resistance of the network,

$R = R_1 + R_p = 100 + 18{\cdot}75 = \mathbf{118{\cdot}75\ \Omega}$

Current through R_1

= current through the main circuit from battery

or $I\,(R_1) = \dfrac{E}{R} = \dfrac{4 \cdot 75}{118 \cdot 75} = \mathbf{0{\cdot}04\ A}$

Potential drop across the parallel combination of R_2, R_3 and R_4,

$V = E -$ potential drop across R_1

$= 4{\cdot}75 - 100 \times 0{\cdot}04 = 0{\cdot}75\ V$

$\therefore \quad I\,(R_2) = I\,(R_3) = \dfrac{V}{50} = \dfrac{0 \cdot 75}{50} = \mathbf{0{\cdot}015\ A}$

and $\quad I\,(R_3) = \dfrac{V}{75} = \dfrac{0 \cdot 75}{75} = \mathbf{0{\cdot}01\ A}$

59. (*a*) Between points A and B, the effective part of the network is as shown in Fig. 1.93 :

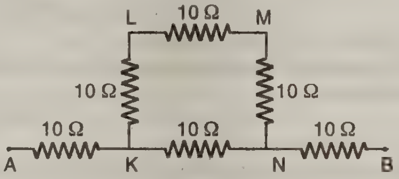

Fig. 1.93

The branch KLMN (having resistance of 10 + 10 + 10 *i.e.* 30 Ω) is parallel to the branch KN (having resistance 10 Ω). Therefore, resistance of the network between points A and B,

$$R = 10 + \frac{30 \times 10}{30 + 10} + 10 = 10 + 7 \cdot 5 + 10$$

$= \mathbf{27{\cdot}5\ \Omega}$

(*b*) Between points A and C, the effective part of the network is as shown in Fig. 1.94 :

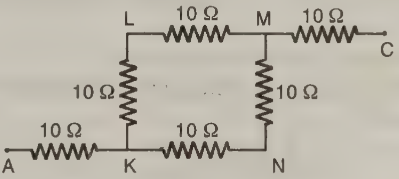

Fig. 1.94

The branch KLM (having resistance of 10 + 10 *i.e.* 20 Ω) is in parallel to the branch KNM (having resistance of 10 + 10 *i.e.* 20 Ω).

Therefore, resistance of the network between points A and C,

$$R = 10 + \frac{20 \times 20}{20 + 20} + 10 = 10 + 10 + 10 = \mathbf{30\ \Omega}$$

60. Proceed as in solved problem no. 1.30.

61. $r = \left(\dfrac{E}{V} - 1\right) R = \left(\dfrac{1 \cdot 5}{1 \cdot 4} - 1\right) \times 14 = \mathbf{1\ \Omega}$

62. $I = \dfrac{E}{R + r} \quad$ or $\quad 0 \cdot 1 = \dfrac{1 \cdot 5}{10 + r} \quad$ or $\quad r = 5\ \Omega$

63. Proceed as in solved problem no. 1.33.

64. $E = 1{\cdot}5\ V$; $V = 1{\cdot}35\ V$; $I = 1{\cdot}5\ A$

Now, $V = I\,R$ or $1{\cdot}35 = 1{\cdot}5 \times R$ or $R = 0{\cdot}9\ \Omega$

Also, $r = \left(\dfrac{E}{V} - 1\right) R = \left(\dfrac{1 \cdot 5}{1 \cdot 35} - 1\right) \times 0 \cdot 9 = \mathbf{0{\cdot}1\ \Omega}$

65. Let r be internal resistance of the cell. Then, current in the circuit,

$$I = \frac{E}{R + r}$$

In first case : $3 = \frac{6 \cdot 6}{1 \cdot 8 + r}$

or $r = \frac{6 \cdot 6}{3} - 1 \cdot 8 = \mathbf{0 \cdot 4\ \Omega}$

In second case : $I = \frac{6 \cdot 6}{2 \cdot 9 + 0 \cdot 4} = \mathbf{2\ A}$

66. $R_p = \frac{6 \times 12}{6 + 12} = 4\,\Omega$

Now, $I = \frac{E}{R_p + r} = \frac{4 \cdot 8}{4 + 2} = \mathbf{0{\cdot}8\ A}$

Let I_1 be current through 6 Ω resistance. Then, current through 12 Ω resistance is $I - I_1$.

Now, $I_1 \times 6 = (I - I_1) \times 12$ or $I_1 \times 6 = (0{\cdot}8 - I_1) \times 12$

or $I_1 = \mathbf{0{\cdot}533\ A}$

Current through 12 Ω resistance

$= I - I_1 = 0{\cdot}8 - 0{\cdot}533 = \mathbf{0{\cdot}267\ A}$

67. Proceed as in problem no. 66.

68. ***When current flows from negative to positive terminal of the battery :***

$V = E - I\,r$ or $8{\cdot}5 = E - 3 \times r$

or $E - 3\,r = 8{\cdot}5$ ...(*i*)

When current flows from positive to negative terminal of the battery :

$V = E + I\,r$ (potential acorss r aids the e.m.f.)

or $11 = E + 2\,r$ ...(*ii*)

Solving equations (*i*) and (*ii*), we get

$r = \mathbf{0{\cdot}5\ \Omega}$ and $E = \mathbf{10\ V}$

69. During charging, potential drop across r aids the e.m.f.

$\therefore$ $V = E + I\,r$ or $3{\cdot}6 = 3 + 1{\cdot}5 \times r$

or $r = \mathbf{0{\cdot}4\ \Omega}$

70. Let R_s be resistance of the series combination of R_1 and R_2.

Then, $R_s = R_1 + R_2 = 6 + 3 = 9\ \Omega$

Further, let R_s' be resistance of the series combination of R_3 and R_4.

Then, $R_s = R_3 + R_4 = 3 + 6 = 9\ \Omega$

If R_p is resistance of the parallel combination of R_s and R_s', then

$$R_p = \frac{R_s \times R_s'}{R_s + R_s'} = \frac{9 \times 9}{9 + 9} = 4 \cdot 5\,\Omega$$

If I is current in the main circuit from the battery, then

$$I = \frac{E}{R_p + r} = \frac{6}{4 \cdot 5 + 1 \cdot 5} = \mathbf{1\ A}$$

Since resistances of the branches APB and AQB are equal, current equal to $I/2$ *i.e.* 0·5 A will flow through each branch.

Now, $V_A - V_P = V_A - 6 \times 0{\cdot}5 = V_A - 3$

and $V_A - V_Q = V_A - 3 \times 0{\cdot}5 = V_A - 1{\cdot}5$

Now, $V_P - V_Q = (V_A - V_Q) - (V_A - V_P)$

$= (V_A - 1{\cdot}5) - (V_A - 3) = \mathbf{1{\cdot}5\ V}$

71. Here, $E_1 = E_2 = 1{\cdot}5\ V$

When batteries are connected in series :

$I = \frac{E_1 + E_2}{R + 2r}$ or $I = \frac{1 \cdot 5 + 1 \cdot 5}{R + 2r}$

or $R + 2\,r = 3$ ...(*i*)

When batteries are connected in parallel :

$I = \frac{E}{R + r/2}$ or $0 \cdot 6 = \frac{1 \cdot 5}{R + r/2}$

or $R + r/2 = 2{\cdot}5$ ...(*ii*)

Solving equations (*i*) and (*ii*), we get

$$r = \frac{1}{3}\,\Omega$$

72. Let r be internal resistance of each cell.

When cells are connected in parallel :

Effective e.m.f. of two cells, E = 2 V

Total internal resistance of the cells, $r' = r/2$

Now, $r' = \left(\frac{E}{V} - 1\right) R$

or $\frac{r}{2} = \left(\frac{2}{1 \cdot 5} - 1\right) \times 5$ or $r = \mathbf{3{\cdot}33\ \Omega}$

73. Here, $R = \frac{17 \times 17}{17 + 17} = 8 \cdot 5\,\Omega$

$\therefore$ $r' = \left(\frac{E}{V} - 1\right) R = \left(\frac{1 \cdot 5}{1 \cdot 4} - 1\right) \times 8 \cdot 5 = \mathbf{1{\cdot}214\ \Omega}$

74. When three cells are connected in parallel,

total internal resistance = $r/3$ and total e.m.f., E = 2 \

$\therefore$ $\frac{r}{3} = \left(\frac{E}{V} - 1\right) R = \left(\frac{2}{1 \cdot 5} - 1\right) \times 5$ or $r = \mathbf{5\ \Omega}$

75. $I = \frac{E}{R + r/2} = \frac{1 \cdot 1}{10 + 2/2} = \mathbf{0{\cdot}1\ \Omega}$

As the two cells are identical, each will supply a curre of 0·1/2 *i.e.* **0·05 A**

76. Here, I = 1800 A, $\sigma = 10^{-9}\ C\ m^{-2}$

Total charge on the surface of earth,

$q = 4\,\pi\,R^2\,\sigma = 4\,\pi \times (6{\cdot}37 \times 10^6)^2 \times 10^{-9}$

If the charge on the surface of earth neutralises in time then resulting current,

$I = \frac{q}{t}$ or $t = \frac{q}{I}$

or $t = \frac{4\,\pi \times (6 \cdot 37 \times 10^6)^2 \times 10^{-9}}{1800} = \mathbf{283{\cdot}3\ s}$

77. ***(a) When the key K is open :***

Each row has a resistance of 2 + 3 *i.e.* 5 Ω.

Since the two rows are in parallel, equivalent resistance the network,

$$R = \frac{5 \times 5}{5 + 5} = \mathbf{2{\cdot}5\ \Omega}$$

(b) When the key K is closed :

The 2 Ω and 3 Ω resistors on the left of the key are parallel. Their equivalent resistance is given by

$$R_p = \frac{2 \times 3}{2 + 3} = \mathbf{1{\cdot}2\ \Omega}$$

Similarly, 2 Ω and 3 Ω resistors on the right of the key a in parallel and equivalent to 1·2 Ω.

Hence, the equivalent resistance of the network,

$R = 1{\cdot}2 + 1{\cdot}2 = \mathbf{2{\cdot}4\ \Omega}$

78. In the steady state (when capacitor is fully charged), r current flows through the branch ECD.

The given network is, therefore, equivalent to the circu shown in Fig. 1.95 :

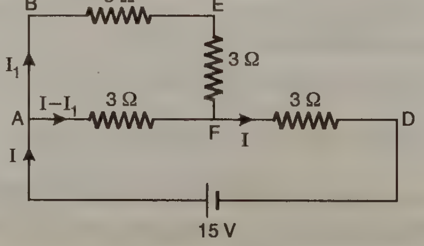

Fig. 1.95

If R is equivalent resistance of the above circuit, then

$$R = \frac{6\times 3}{6+3} + 3 = 5\,\Omega$$

Therefore, current in the main circuit, $I = \frac{15}{5} = 3$ A

Current through the arm BEF, $I_1 = \frac{I\times 3}{6+3} = \frac{3\times 3}{6+3} = 1$ A

Now, a current of 3 – 1 *i.e.* 2 A will flow through the branch AF and a current of 2 + 1 *i.e.* 3 A will flow through the branch FD.

Since no current flows through the branch ECD, potential difference across the capacitor

= potential difference between points E and D

= potential drop across EF + potential drop across FD

$= 3 \times 1 + 3 \times 3 = \mathbf{12\ V}$

79. Net e.m.f., $E = E_1 + (-E_2) = 20 + (-8) = 12$ V

Total resistance, $R = R_1 + R_2 = 3 + 1 = 4\,\Omega$

Net current in the circuit, $I = \frac{E}{R} = \frac{12}{4} = 3$ A

Now, $V_A - V_B = E_1 -$ potential drop across R_1

$= 20 - 3 \times 3 = \mathbf{11\ V}$

Aliter. $V_A - V_B = E_2 +$ potential drop across R_2

$= 8 + 1 \times 3 = \mathbf{11\ V}$

CHAPTER

2

Electrical Measurements

2.01. KIRCHHOFF'S LAWS

Ohm's law is useful in dealing with simple electrical circuits only. The study of the circuits containing more than one source of e.m.f. becomes difficult with the help of Ohm's law. In 1842, Kirchhoff put forward the following two laws to study complicated electrical circuits :

Kirchhoff's first law. *It states that the algebraic sum of the currents meeting at a point in an electrical circuit is always zero.* It is also called ***junction rule.***

This law is based upon the fact that in an electrical circuit, a point can neither act as a source of charge nor the charge can accumulate at that point.

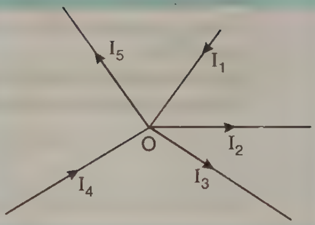

Fig. 2.01

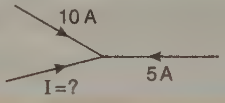
Self-test Questions

Calculate the unknown current in the figure given below :



Explanation. Consider a point O in an electrical circuit at which currents I_1, I_2, I_3, I_4 and I_5 are flowing through five conductors in the directions as shown in Fig. 2.01. Let us adopt the following sign convention :

The currents flowing in a conductor towards the junction of conductors is taken as positive and the current flowing away from the junction is taken as negative.

Likewise, currents I_1 and I_4 flowing towards the point O are positive, while the currents I_2, I_3 and I_5 are negative.

Therefore, according to Kirchhoff's first law,

$$I_1 + (-I_2) + (-I_3) + I_4 + (-I_5) = 0$$

or $$I_1 - I_2 - I_3 + I_4 - I_5 = 0$$

Kirchhoff's second law. *It states that in any closed part of an electrical circuit, the algebraic sum of the e.m.fs. is equal to the algebraic sum of the products of the resistances and currents flowing through them.* It is also called ***loop rule.***

This law is based upon the law of conservation of energy.

Explanation. Consider a closed electrical circuit ABCD containing two cells of e.m.fs. E_1 and E_2 and five resistances R_1, R_2, R_3, R_4 and R_5 as shown in Fig. 2.02.

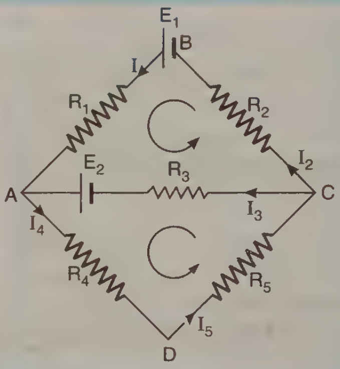


Fig. 2.02

Let us adopt the following sign conventions :

(*i*) The current flowing in anticlockwise direction is positive.

(*ii*) The e.m.f. of a cell is taken positive, if it sends current in the circuit in anticlockwise direction and negative, if the current due to the cell flows in clockwise direction.

Let us consider the closed part ABCA of the electrical circuit. The cell of e.m.f. E_1 will send current in anticlockwise direction and the cell of e.m.f. E_2 will send current in clockwise direction. Thus, e.m.f. E_1 is positive, while E_2 is negative.

Therefore, total e.m.f. of the closed part ABCA $= E_1 + (-E_2) = E_1 - E_2$

Also, in closed part ABCA, currents I_1 and I_2 flow in anticlockwise direction, while the current I_3 flows in clockwise direction. Therefore, in the closed part ABCA,

algebraic sum of the products of resistances and currents in them

$$= I_1R_1 + I_2R_2 + (-I_3)R_3 = I_1R_1 + I_2R_2 - I_3R_3$$

Therefore, for closed part ABCA, according to Kirchhoff's second law, we have

$$E_1 - E_2 = I_1R_1 + I_2R_2 - I_3R_3$$

Similarly, it can be found that for closed part ACDA,

$$E_2 = I_3R_3 + I_4R_4 + I_5R_5$$

2.02. WHEATSTONE BRIDGE

It is one of the accurate arrangements for measuring an unknown resistance.

Four resistances P, Q, R and X are connected to form a quadrilateral. A galvanometer and a tapping key K_1 (called galvanometer key) are connected between points B and D, while a battery and a one way key K_2 (called battery key) are connected between points A and C [Fig. 2.03]. Usually, P and Q, called *ratio* *arms*, are known resistances ; R is a variable resistance (resistance box) and X is the unknown resistance. The value of resistance R is so adjusted that on pressing key K_1, the galvanometer does not give deflection. It implies that points B and D are at the same potential. In such a case, the bridge is said to be ***balanced***. For a balanced bridge, it can be proved that

$$\frac{P}{Q}=\frac{R}{X}$$

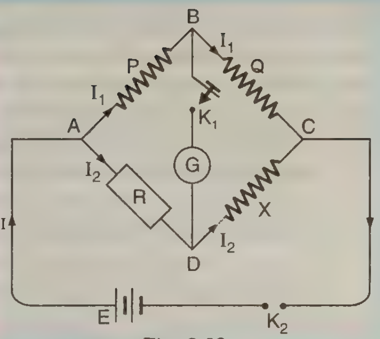

Fig. 2.03

Proof. Let I be the current in the main circuit. At point A, say current equal to I_1 flows through resistance P and the rest $I - I_1 = I_2$ (say) flows through resistance R. When the bridge is in balanced state, points B and D are at the same potential and therefore no current will flow through galvanometer *i.e.* current I_1 will flow as such through Q, while I_2 through X. At point C, the currents through Q and X add up so as to send a total current I through the circuit. Let V_A, V_B, V_C and V_D be electric potentials of points A, B, C and D respectively.

Now, potential difference across P *i.e.* $V_A - V_B = I_1 P$ ...(2.01)

Potential difference across Q *i.e.* $V_B - V_C = I_1 Q$ ...(2.02)

Potential difference across R *i.e.* $V_A - V_D = I_2 R$ ...(2.03)

Potential difference across X *i.e.* $V_D - V_C = I_2 X$ ...(2.04)

When the bridge is in balanced state, no current flows along the path between points B and D. Therefore, points B and D are at same potential *i.e.* $V_B = V_D$. In equations (2.03) and (2.04), replacing V_D by V_B we have

$$V_A - V_B = I_2 R \qquad ...(2.05)$$

and

$$V_B - V_C = I_2 X \qquad ...(2.06)$$

From equations (2.01) and (2.05), we have

$$I_1 P = I_2 R \qquad ...(2.07)$$

From equations (2.02) and (2.06), we have

$$I_1 Q = I_2 X \qquad ...(2.08)$$

Dividing equation (2.07) by (2.08), we have

$$\frac{P}{Q}=\frac{R}{X} \qquad ...(2.09)$$

As we know the values of P, Q and R, the value of unknown resistance X can be found. It may be remembered that the bridge is most sensitive, when all the four resistances are of the same order.

Key point

When the bridge is balanced, the path BD may be considered as an open path. Therefore, even when the galvanometer key (K_1) is kept pressed, no current flows along the path BD.

Key point

Wheatstone bridge is most sensitive, when resistances in the four ratio arms are of the same order.

Merits of Wheatstone bridge. Wheatstone bridge method for measuring an unknown resistance has the following merits over the other methods for measuring the resistance :

1. It is a null method. Therefore, the measurement of resistance made by this method is not affected by the internal resistance of the battery used.

2. As no measurement of current or potential difference is involved, the measurements are not affected because of the fact that the ammeters and voltmeters are not ideal ones.

3. The value of unknown resistance can be measured to a very high degree of accuracy by increasing the ratio of the resistances in arms P and Q.

Key point

The measurement of resistance by Wheatstone bridge is not affected by the internal resistance of the cell.

Watch out !

To avoid inductive effects*, the battery key should be pressed first and the galvanometer key afterwards !

2.03. PRINCIPLE OF WHEATSTONE BRIDGE (FROM KIRCHHOFF'S LAWS)

Four resistances P, Q, R and X are connected across the four arms of Wheatstone bridge as shown in Fig. 2.04. A tapping key K_1 and a galvanometer G are connected between points B and D, whereas a battery of e.m.f. E and a key K_2 are connected between points A and C. The value of resistance R is adjusted, so that on putting plug in key K_2 and pressing the tapping key K_1, the galvanometer shows no deflection. Then, the bridge is said to be balanced. As said earlier, for a balanced bridge,

$$\frac{P}{Q}=\frac{R}{X}$$

It is called condition for balanced wheatstone bridge.

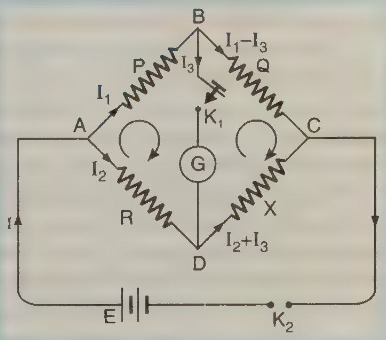

Fig. 2.04

To obtain the condition of balanced bridge using Kirchhoff's laws. When the plug is inserted in the key K_2, the current I enters the network at point A and a part I_1 (say) flows through resistance P and a part I_2 through resistance R. On pressing key K_1, suppose that current I_3 flows through galvanometer G (if we suppose that point B is at higher potential than D). According to Kirchhoff's first law, current $I_1 - I_3$ will flow through resistance Q. At point D, current I_3 flowing through galvanometer G combines with current I_2 flowing through resistance R, so that current $I_2 + I_3$ passes through resistance X. Therefore, at point C, a net current $(I_1 - I_3 + I_2 + I_3)$ *i.e.* $(I_1 + I_2)$ *i.e.* I flows from point C to the negative pole of the battery. Let us consider that current flowing in clockwise direction is positive.

---

* Refer to Chapter on Electromagnetic Induction – Unit IV.

Applying Kirchhoff's second law, for closed part ABDA of the circuit :

$$I_1 P + I_3 G - I_2 R = 0 \qquad ...(2.10)$$

For closed part BCDB of the circuit :

$$(I_1 - I_3) Q - (I_2 + I_3) X - I_3 G = 0 \qquad ...(2.11)$$

The resistance R is adjusted in such a way that points B and D are at the same potential, so that current I_3 passing through the galvanometer is zero. It is indicated by zero deflection in the galvanometer. The bridge is then said to be balanced.

As there is no deflection in galvanometer on pressing key K_1, $I_3 = 0$. In equation (2.10), setting $I_3 = 0$, we get

$$I_1 P - I_2 R = 0$$

or

$$I_1 P = I_2 R \qquad ...(2.12)$$

Also setting $I_3 = 0$ in equation (2.11), we get

$$I_1 Q = I_2 X \qquad ...(2.13)$$

Dividing equation (2.12) by (2.13), we get

$$\frac{P}{Q} = \frac{R}{X}$$

It proves the condition for balanced Wheatstone bridge.

2.04. SLIDEWIRE BRIDGE

A slide wire bridge is also known as **metre bridge.**

Principle. *It is constructed on the principle of balanced Wheatstone bridge, i.e.* when a wheatstone bridge is balanced,

$$\frac{P}{Q} = \frac{R}{X},$$

where the letters have their usual meanings.

Construction. It consists of a wooden board, over which constantan wire AC of one metre in length is stretched between two copper strips. A metre scale is also fitted on the wooden board parallel to the length of the wire. Another central copper strip is fitted on the wooden board to provide two gaps across which a resistance box R and the unknown resistance X are connected. One terminal of a sensitive galvanometer is connected to the terminal D, provided on the central copper strip and the other to a jockey, which can be slided over the wire to balance the bridge. The circuit is now exactly the same as that of the Wheatstone bridge [Fig. 2.05]. The resistance of wire between points A and B (B is the position of jockey in balanced state of the bridge) represents ratio arm P and that of wire between B and C represents Q. Therefore, when bridge is balanced

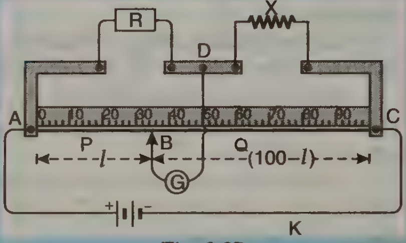

Fig. 2.05

$$\frac{P}{Q} = \frac{R}{X}$$

Applications of metre bridge. A metre bridge can be used to measure an unknown resistance or to compare the values of two unknown resistances.

1. ***To measure an unknown resistance.*** To find the value of unknown resistance X, the circuit as shown in Fig. 2.05 is arranged. The bridge can be balanced by moving the jockey over the wire. The bridge is said to be balanced, when the jockey is at a point B on the wire, such that galvanometer does not give any deflection. For this, resistance in the left gap is introduced with the help of resistance box R and its value is adjusted so as to obtain the balance point. In practice, the value of R is so adjusted that the balance point lies between 35 cm and 65 cm marks. Suppose that when bridge has been balanced, AB $= l$. Then, BC $= 100 - l$. The resistance of wire between points A and B is taken as P and that of the portion between B and C is taken as Q. If wire of the metre bridge is of uniform area of cross-section, then

$$P \propto l \quad \text{and} \quad Q \propto 100 - l$$

$$\therefore \quad \frac{P}{Q} = \frac{l}{(100 - l)}$$

Self-test Questions

Why do we prefer to obtain the balance point between 35 cm and 65 cm marks ?

From the principle of Wheatstone bridge,

$$\frac{P}{Q} = \frac{R}{X}$$

$$\therefore \qquad \frac{R}{X} = \frac{l}{(100-l)}$$

$$\text{or} \qquad X = R\,\frac{(100-l)}{l} \qquad \text{...(2.14)}$$

Knowing the values of R and l, the value of X can be found.

2. ***To compare two unknown resistances.*** For comparing two unknown resistances R_1 and R_2, the circuit as shown in Fig. 2.05 is arranged. First, the resistance R_1 is connected in place of unknown resistance X. The jockey is moved over the bridge wire gently and by adjusting the value of R, the balance point is obtained. The bridge is said to be balanced, when the jockey is at a point B on the wire, such that galvanometer does not give any deflection. In such a case, if AB = l_1, then BC = $100 - l_1$. The resistance of the bridge wire between the points A and B is ratio arm P and that between points B and C corresponds to ratio arm Q. Since the bridge wire is of uniform area of cross-section,

$$P \propto l_1 \qquad \text{and} \qquad Q \propto 100 - l_1$$

$$\therefore \qquad \frac{P}{Q} = \frac{l_1}{(100-l)}$$

From the principle of Wheatstone bridge,

$$\frac{P}{Q} = \frac{R}{R_1} \qquad (\because X = R_1)$$

$$\therefore \qquad \frac{R}{R_1} = \frac{l_1}{(100-l_1)}$$

$$\text{or} \qquad R_1 = \frac{R\,(100-l_1)}{l_1} \qquad \text{...(2.15)}$$

Now, the experiment is repeated with the other unknown resistance R_2. If l_2 is the balancing length of the bridge wire between the points A and B, then it can be obtained that

$$R_2 = \frac{R\,(100-l_2)}{l_2} \qquad \text{...(2.16)}$$

Dividing equation (2.15) by (2.16), we get

$$\frac{R_1}{R_2} = \frac{R\,(100-l_1)}{l_1} \times \frac{l_2}{R\,(100-l_2)}$$

$$\text{or} \qquad \frac{R_1}{R_2} = \frac{l_2}{l_1} \times \frac{(100-l_1)}{(100-l_2)} \qquad \text{...(2.17)}$$

Knowing the values of l_1 and l_2, the ratio R_1/R_2 can be found.

3. ***To measure the unknown temperature..*** We know that resistance of a conductor increases with increase of temperature. The resistance of a conductor at temperature θ is given by

$$R = R_0\,(1 + \alpha\,\theta), \qquad \text{...(2.18)}$$

where R_0 is resistance of the conductor at 0°C and α is temperature coefficient of resistance of the conductor.

From equation (2.18), we have

$$R - R_0 = R_0\,\alpha\,\theta \qquad \text{...(2.19)}$$

If R_{100} is resistance of the conductor at 100°C, then equation (2.19) may be expressed as

$$R_{100} - R_0 = R_0\,\alpha \times 100 \qquad \text{...(2.20)}$$

Dividing equation (2.20) by (2.19), we obtain

$$\theta = \frac{R - R_0}{R_{100} - R_0} \times 100 \qquad \text{...(2.21)}$$

The equation (2.21) may be used to find the unknown temperature of a hot bath by using the circuit diagram shown in Fig. 2.05. The unknown resitance X (in the form of a metallic wire) is immersed in ice and its resistance R_0 at 0°C is measured. The unknown resistance is then maintained at a temperature of 100°C (by placing the wire in steam) and its resistance R_{100} at 100°C is measured. Finally, the unknown resistance is immersed in hot bath at unknown temperature θ and experiment is repeated to measure its resistance R_θ at θ°C. Then, by substituting the value of R_0, R_{100} and R_θ in equation (2.21), the unknown temperature of the hot bath can be found.

2.05. POTENTIOMETER

A potentiometer is used to compare e.m.fs. of two cells or to measure internal resistance of a cell.

Principle. The principle of potentiometer states that *when a constant current is passed through a wire of uniform area of cross-section, the potential drop across any portion of the wire is directly proportional to the length of that portion.*

Construction. A potentiometer consists of a number of segments of wire of uniform area of cross-section stretched over a wooden board between two thick copper strips. Each segment of wire is 100 cm long. The wire is usually of constantan or manganin. A metre rod is fixed parallel to its length [Fig. 2.06]. A battery connected across the two end terminals sends current through the wire, which is kept constant by using a rheostat.

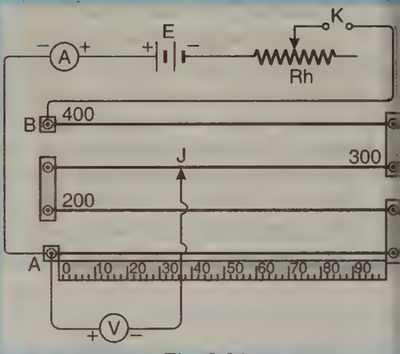

Fig. 2.06

Theory. Let V be potential difference across certain portion of wire, whose resistance is R. If I is the current through the wire, then

$$V = IR$$

We know that $R = \rho \frac{l}{A}$,

where l, A and ρ are length, area of cross-section and resistivity of the material of wire respectively.

$$\therefore \quad V = I\rho\frac{l}{A}$$

If a constant current is passed through the wire of uniform area of cross-section, then I and A are constants. Since, for a given wire, ρ is also constant, we have

$$V = \text{constant} \times l$$

$$\text{or} \quad V \propto l \qquad \text{...(2.22)}$$

Hence, if a constant current flows through a wire of uniform area of cross-section, then potential drop along the wire is directly proportional to the length of the wire.

Key point

The principle of potentiometer requires that

(*i*) potentiometer wire should be o uniform area of cross-section and

(*ii*) current through the wire should remai constant.

Applications of a potentiometer. A potentiometer can be put to the following uses :

1. ***To compare e.m.fs. of two cells.*** Two cells, whose e.m.fs. are E_1 and E_2, can be compared by making use of the circuit as shown in Fig. 2.07. The positive poles of both the cells are connected to the terminal A of the potentiometer. The negative poles of the two cells are connected to terminals 1 and 2 of a two-way key, while its common terminal is connected to a jockey J through a galvanometer G. An auxiliary or driver battery of e.m.f. E, an ammeter A, rheostat Rh and a one way key K are connected between the end terminals A and B of the potentiometer. Thus, the positive poles of the two cells as well as the positive pole of auxiliary battery are connected at the common point A. It may be pointed that e.m.f. of auxiliary battery should always be greater than e.m.f. of either of the two cells.

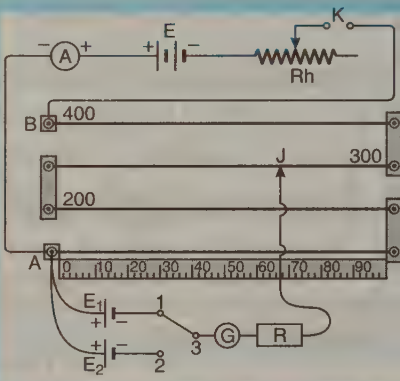

Fig. 2.07

To compare e.m.fs. of the two cells, a constant current is passed through the potentiometer wire between the points A and B. The current is kept constant by using the rheostat.

When the plug is put in the gap between the terminals 1 and 2 of the two-way key, the cell of e.m.f. E_1 will come in the circuit. Suppose that balancing length (length of wire between points A and J) is l_1. If x is the resistance per unit length of the potentiometer wire and I, the constant current flowing through it, then

$$E_1 = (x\,l_1)\,I \qquad \text{...(2.23)}$$

When the key is put in the gap between the terminals 2 and 3 after moving from the gap between 1 and 3, the cell of e.m.f. E_2 will be included in the circuit. Let the balancing length be l_2 in this case. Then,

$$E_2 = (x\,l_2)\,I \qquad \text{...(2.24)}$$

Dividing equation (2.23) by equation (2.24), we get

$$\frac{E_1}{E_2} = \frac{l_1}{l_2} \qquad \text{...(2.25)}$$

Key point

The e.m.f. of auxiliary battery mus always be greater than the e.m.f. of eithe of the two cells.

Key point

The positive terminals of the two cells as well as that of auxiliary battery must be connected at the same common terminal.

2. ***To measure internal resistance of a cell.*** The internal resistance of a cell of m.f. E can be found by setting up the circuit as shown in Fig. 2.08. Let E′ be e.m.f. f the auxiliary battery. A constant current I is maintained through the potentiometer ire with the help of the rheostat.

Plug in the key K_2 is kept out and the jockey is moved over the potentiometer ire so as to balance the e.m.f. E of the cell, whose internal resistance is to be found. et l_1 be the balancing length of the potentiometer wire between point A and jockey If x is resistance per unit length of the wire, then

$$E = (x\,l_1)\,I \qquad ...(2.26)$$

With the help of resistance box S, introduce resistance, say S and then put the lug in key K_2. Now, find the balance point for the terminal potential difference V etween the two poles of the cell. If l_2 is the balancing length, then

$$V = (x\,l_2)\,I \qquad ...(2.27)$$

Dividing equation (2.26) by (2.27), we have

$$\frac{E}{V} = \frac{l_1}{l_2} \qquad ...(2.28)$$

The internal resistance* of the cell is given by

$$r = \left(\frac{E}{V} - 1\right)S$$

Using equation (2.28), we have

$$r = \left(\frac{l_1}{l_2} - 1\right)S$$

or

$$r = \frac{l_1 - l_2}{l_2} \times S \qquad ...(2.29)$$

Knowing the values of l_1, l_2 and S, the internal resistance r of the cell can be found.

Note. Apart from these uses, a potentiometer can be used to compare unknown resistances and to calibrate a voltmeter or an ammeter.

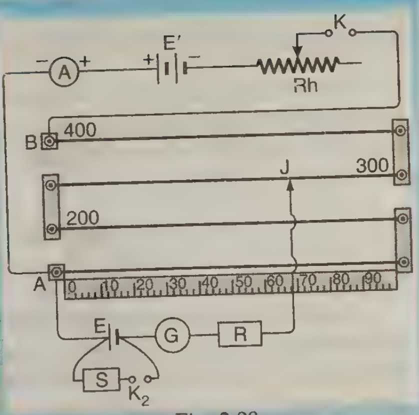

Fig. 2.08

Watch out !

A voltmeter, when connected across a cell, always draws some current and therefore it cannot be used to measure the e.m.f. of a cell. In case of a potentiometer, when the e.m.f. of a cell is balanced against potential drop across a certain length of wire, the wire draws current only from the auxiliary battery. It does not draw any current from the cell and therefore by calibrating the potentiometer wire with a standard cell, a potentiometer can be used to measure e.m.f. of a cell !

SOLVED NUMERICAL PROBLEMS

Type A. On Kirchhoff's laws

Problem 2.01. In the network shown in Fig. 2.09, $E_1 = 6$ V, $E_2 = 4$ V, $R_1 = 2\,\Omega$, $R_2 = 3\,\Omega$ and $R_3 = 5\,\Omega$. Find the currents passing through the resistors R_1, R_2 and R_3.

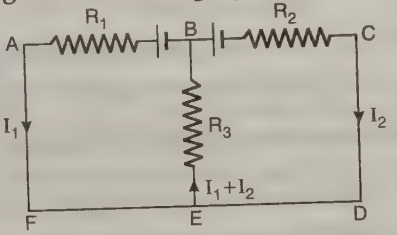

Fig. 2.09

Sol. Suppose that due to battery of e.m.f E_1, current I_1 flows through resistor R_1 and that due to E_2, current I_2 flows through resistor R_2. Then, according to Kirchhoff's first law, current $(I_1 + I_2)$ will flow through resistor R_3 as shown in Fig. 2.09.

In closed part ABEFA of the circuit :

$$I_1 R_1 + (I_1 + I_2) R_3 = E_1$$

or $$I_1 \times 2 + (I_1 + I_2)\,5 = 6$$

or $$7\,I_1 + 5\,I_2 = 6 \qquad ...(i)$$

In closed part BCDEB of the circuit :

$$I_2 R_2 + (I_1 + I_2) R_3 = E_2$$

or $$I_2 \times 3 + (I_1 + I_2)\,5 = 4$$

or $$5\,I_1 + 8\,I_2 = 4 \qquad ...(ii)$$

Multiplying equation (*i*) by 8, equation (*ii*) by 5 and then subtracting, we have

$$(7\,I_1 + 5\,I_2) \times 8 - (5\,I_1 + 8\,I_2) \times 5 = 6 \times 8 - 4 \times 5$$

or $$31\,I_1 = 28 \quad \text{or} \quad I_1 = \frac{28}{31}\,A$$

Substituting for I_1 in equation (*i*), we get

$$7 \times \frac{28}{31} + 5\,I_2 = 6 \quad \text{or} \quad I_2 = -\frac{2}{31}\,A$$

The current through resistor R_3,

$$I_1 + I_2 = \frac{28}{31} + \left(\frac{-2}{31}\right) = \frac{26}{31}\,A$$

Problem 2.02. Two cells of e.m.f. 1·5 V and 2·0 V and internal resistances 1 Ω and 2 Ω respectively are connected in parallel so as to send current in the same direction through an external resistance of 5 Ω. (*a*) Draw the circuit diagram. (*b*) Using Kirchhoff's laws, calculate current through each branch of the circuit and potential across the 5 Ω resistance. (C.B.S.E. 1995)

Sol. (*a*) ***Circuit diagram.*** Let the e.m.f. of two cells be represented by E_1 and E_2 and their internal resistances be r_1 and r_2 respectively. The two cells have been connected in parallel to the external resistance R as shown in Fig. 2.10.

(*b*) Here, $E_1 = 1{\cdot}5\ V\ ;\ E_2 = 2{\cdot}0\ V\ ;$

$$r_1 = 1\,\Omega\ ;\ r_2 = 2\,\Omega\ ;\ R = 5\,\Omega$$

---

*Refer to equation (1.49) of Chapter 1.

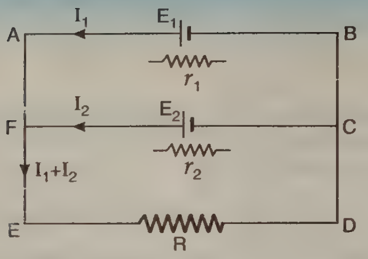

Fig. 2.10

Let I_1 and I_2 be currents due to the cells E_1 and E_2 respectively. As the currents I_1 and I_2 flow into point F ; according to Kirchhoff's first law, current $I_1 + I_2$ will flow out from point F and pass through resistance R.

Applying Kirchhoff's second law to the closed part ABDEA of the circuit, we have

or $$E_1 = I_1 r_1 + (I_1 + I_2) R$$

or $$1{\cdot}5 = I_1 \times 1 + (I_1 + I_2) \times 5$$

or $$6 I_1 + 5 I_2 = 1{\cdot}5 \qquad ...(i)$$

Applying Kirchhoff's second law to the closed part FCDEF of the circuit, we have

$$E_2 = I_2 r_2 + (I_1 + I_2) R$$

or $$2{\cdot}0 = I_2 \times 2 + (I_1 + I_2) \times 5$$

or $$5 I_1 + 7 I_2 = 2{\cdot}0 \qquad ...(ii)$$

Solving equations (*i*) and (*ii*), we obtain

$$I_1 = 0{\cdot}0294 \text{ A} \quad \text{and} \quad I_2 = 0{\cdot}2647 \text{ A}$$

Potential difference across $R = (I_1 + I_2) R$

$$= (0{\cdot}0294 + 0{\cdot}2647) \times 5 = 1{\cdot}4705 \text{ V}$$

Problem 2.03. Three cells are connected in parallel with their like poles connected together with wires of negligible resistance. If the e.m.fs. of the cells are 2, 1 and 4 V respectively and their internal resistances are 4, 3 and 2 Ω respectively, find the current through each cell.

Sol. Here, $E_1 = 2\text{ V} ; E_2 = 1\text{ V} ; E_3 = 4\text{ V}$

and $r_1 = 4\,\Omega ; r_2 = 3\,\Omega ; r_3 = 2\,\Omega$

Let the currents I_1, I_2 and I_3 flowing from the three cells be as shown in Fig. 2.11.

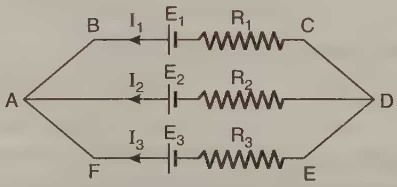

Fig. 2.11

Applying Kirchhoff's first law at point A, we have

$$I_1 + I_2 + I_3 = 0 \qquad ...(i)$$

Applying Kirchhoff's second law to the closed part ABCDA of the circuit, we have

$$I_1 r_1 - I_2 r_2 = E_1 - E_2 \quad \text{or} \quad I_1 \times 4 - I_2 \times 3 = 2 - 1$$

or $$4 I_1 - 3 I_2 = 1 \qquad ...(ii)$$

Applying Kirchhoff's second law to the closed part ADEFA of the circuit, we have

$$I_2 r_2 - I_3 r_3 = E_2 - E_3 \quad \text{or} \quad I_2 \times 3 - I_3 \times 2 = 1 - 4$$

or $$3 I_2 - 2 I_3 = -3 \qquad ...(iii)$$

Solving equations (*i*), (*ii*) and (*iii*), we obtain

$$I_1 = -\frac{2}{13}\text{ A} ; I_2 = -\frac{7}{13}\text{ A and } I_3 = \frac{9}{13}\text{ A}$$

Problem 2.04. Two cells of e.m.f. 2 V and 1 V and internal resistances 1 Ω and 2 Ω respectively have the positive terminals connected by a wire of 10 Ω resistan and their negative terminals by a wire of 4 Ω resistanc Another coil of 10 Ω is connected between the midd points of these wires. Find the potential difference acro the 10 Ω coil. (*Karnataka, 1988*

Sol. The positive terminals of the cells E_1 and E_2 a connected to the wire AE of resistance 10 Ω and negati terminals to the wire BD of resistance 4 Ω. The resistan of 10 Ω is connected between the middle points F and of the wires AE and BD respectively. [Fig. 2.12]

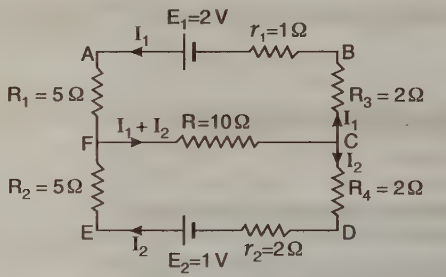

Fig. 2.12

$$\therefore \quad R_1 = R_2 = \frac{10}{2} = 5\,\Omega ; R_3 = R_4 = \frac{4}{2} = 2\,\Omega.$$

The distribution of current in various branches is show in the figure.

In closed part ABCFA of the circuit :

$$I_1 \times r_1 + I_1 \times R_1 + (I_1 + I_2) R + I_1 \times R_3 = E_1$$

or $$I_1 \times 1 + I_1 \times 5 + (I_1 + I_2) \times 10 + I_1 \times 2 = 2$$

or $$9 I_1 + 5 I_2 = 1 \qquad ...($$

In the closed part CDEFC of the circuit :

$$I_2 \times r_2 + I_2 \times R_2 + (I_1 + I_2) R + I_2 \times R_4 = E_2$$

or $$I_2 \times 2 + I_2 \times 5 + (I_1 + I_2) \times 10 + I_2 \times 2 = 1$$

or $$10 I_1 + 19 I_2 = 1 \qquad ...(ii$$

Solving equations (*i*) and (*ii*), we have

$$I_2 = \frac{14}{121}\text{ A} \qquad \text{and } I_2 = -\frac{1}{121}\text{ A}$$

Therefore, current through resistance R,

$$I_1 + I_2 = \frac{14}{121} + \left(-\frac{1}{121}\right) = \frac{13}{121}\text{ A}$$

Potential difference across the resistance R

$$= (I_1 + I_2) R = \frac{13}{121} \times 10 = \mathbf{1{\cdot}0744 \text{ V}}$$

Problem 2.05. Find the equivalent resistance betwee the points X and Y of the network of resistors shown i Fig. 2.13.

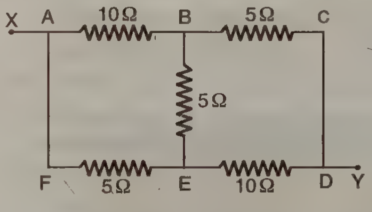

Fig. 2.13

Ans. Let R be equivalent resistance of the network c resistors in Fig. 2.13. In order to find R, connect a battery c n.f. E across the points X and Y as shown in Fig. 2.14.

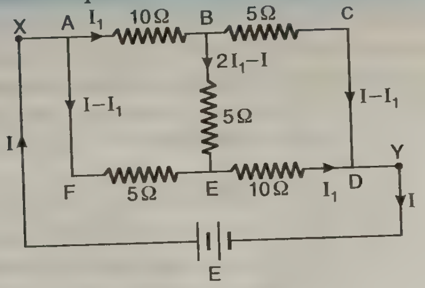

Fig. 2.14

If I is current drawn by the network from the battery, en

$$R=\frac{E}{I} \qquad ...(i)$$

Suppose that when current I enters at point A, a part I_1 ows along path AB. Then, according to Kirchhoff's first law, ne remaining part $(I-I_1)$ will flow along path AFE. By ymmetry, the current I flowing out from point D will be omposed of part I_1 from the path ED and $(I-I_1)$ from the ath BCD. Again, according to Kirchhoff's first law, the urrent along path BE will be $I_1-(I-I_1)$ *i.e.* $2I_1-I$. The istribution of current in various branches of the circuit is as hown in figure.

In closed part ABEFA of the circuit :

$$10I_1+5(2I_1-I)-5(I-I_1)=0$$

or $$25I_1-10I=9 \quad \text{or} \quad I_1=\frac{2}{5}I$$

In closed part XAFEDYX of the circuit :

$$E=5(I-I_1)+10I_1$$

$$=5I+5I_1=5I+5\times\frac{2}{5}I=7I$$

Subsituting for E in equation (*i*), we have

$$R=\frac{7I}{I}=7\,\Omega$$

Type B. On Wheatstone bridge

Problem 2.06. Four resistances of 15 Ω, 12 Ω, 4 Ω and 10 Ω respectively are connected in cyclic order to form a Wheatstone's network. Is the network balanced ? If not, calculate the resistance to be connected in parallel with the resistance of 10 Ω to balance the network.

(*Karnataka, 1974 S*)

Sol. Let P = 15 Ω ; Q = 12 Ω ; S = 4 Ω ; R = 10 Ω

The resistances of 15 Ω, 12 Ω, 4 Ω and 10 Ω are connected in cyclic order as shown in Fig. 2.15.

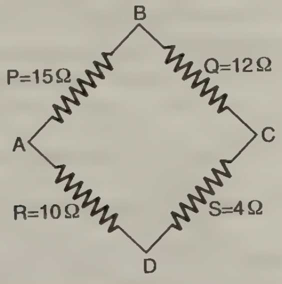

Fig. 2.15

Now, $$\frac{P}{Q}=\frac{15}{12}=1\cdot25\,; \qquad \frac{R}{S}=\frac{10}{4}=2\cdot5$$

Since $\frac{P}{Q}$ is not equal to $\frac{R}{S}$, the bridge is **not balanced**.

To balance the network, suppose a resistance X is connected in parallel to R = 10 Ω, so that the bridge is balanced. If R′ is effective resistance between points A and D, then

$$\frac{1}{R'}=\frac{1}{10}+\frac{1}{X} \qquad ...(i)$$

Since the bridge is now balanced,

$$\frac{P}{Q}=\frac{R'}{S} \quad \text{or} \quad R'=S\times\frac{P}{Q}=4\times\frac{15}{12}=5\,\Omega$$

Substituting for R′ in equation (*i*), we have

$$\text{or} \quad \frac{1}{5}=\frac{1}{10}+\frac{1}{X} \quad \text{or} \quad \frac{1}{X}=\frac{1}{5}-\frac{1}{10}=\frac{1}{10} \quad \text{or } \mathbf{X=10\,\Omega}$$

Problem 2.07. A potential difference of 4 volt is applied between the points A and B shown in the network drawn in the Fig. 2.16. Calculate (*i*) equivalent resistance of the network across the points A and B and (*ii*) the magnitudes of currents flowing in arms AFCEB and AFDEB.

(*H.P.S.S.C.E. 2000, 1998 ; C.B.S.E. 1998 S*)

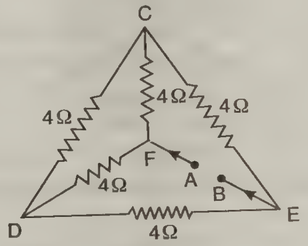

Fig. 2.16

Ans. After connecting a battery of e.m.f. E = 4 V between the points A and B, the given network can be redrawn as shown in Fig. 2.17.

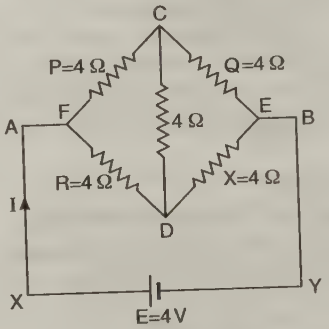

Fig. 2.17

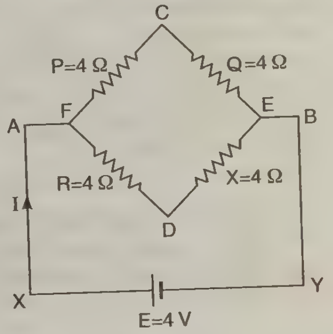

Fig. 2.18

The given network is a Wheatstone bridge arrangement.

Further, as $\frac{P}{Q}=\frac{R}{X}$, the bridge is in balanced slate. As such, no current can flow along the path CD. In other words, CD can be treated as an open path as shown in Fig. 2.18.

(*i*) Now, path FCE contains two resistances, (each of 4 Ω) connected in series. If R_1 is resistance of path FCE, then

$$R_1=P+Q=4+4=8\,\Omega$$

Similarly, if R_2 is resistance of path FDE, then

$$R_2=R+X=4+4=8\,\Omega$$

Now, the path FCE of resistance R_1 and FDE of resistance R_2 are connected in parallel. If R′ is equivalent resistance of the given network between points A and B, then

$$\frac{1}{R'} = \frac{1}{R_1} + \frac{1}{R_2} = \frac{1}{8} + \frac{1}{8} = \frac{1}{4}$$

or $R' = 4\ \Omega$

(ii) Let I be the current in the main circuit due to battery.

Then, $I = \frac{E}{R'} = \frac{4}{4} = 1\ A$

Further, suppose that I_1 and I_2 are currents along paths FCE and FDE respectively. Since the two paths FCE and FDE are of equal resistances, the current I in the main circuit will divide equally along the two paths *i.e.* current in the arms AFCEB and AFDEB are given by

$$I_1 = I_2 = I/2 = 1/2 = 0{\cdot}5\ A$$

Problem 2.08. Find the value of unknown resistance X in the circuit shown in Fig. 2.19, if no current flows through the section AO. Also calculate the current drawn by the circuit from the battery of e.m.f. 6 V and negligible internal resistance. *(C.B.S.E. 2002)*

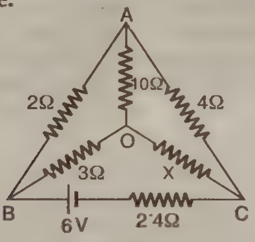

Fig. 2.19

Sol. The given circuit is equivalent to the circuit shown in Fig. 2.20.

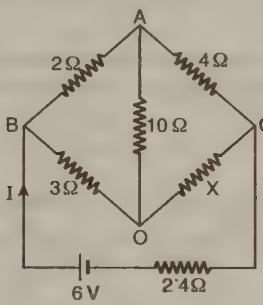

Fig. 2.20

Let I be the current drawn by the circuit from the battery.

As no current flows through branch AO of the circuit, the circuit is a balanced Wheatstone bridge. Therefore,

$$\frac{2}{4} = \frac{3}{X} \quad \text{or} \quad X = \frac{4 \times 3}{2} = 6\ \Omega$$

Since the branch AO acts as open path (no current flows along branch AO), the 10 Ω resistance of the circuit is ineffective. Hence, the network is equivalent to the circuit shown in Fig. 2.21.

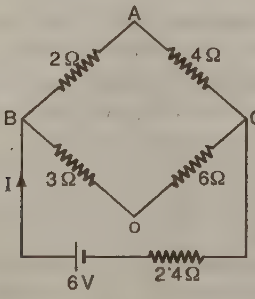

Fig. 2.21

Let R_1 and R_2 be resistances of the paths BAC and BOC of the circuit. Then,

$$R_1 = 2 + 4 = 6\ \Omega \quad \text{and} \quad R_2 = 3 + 6 = 9\ \Omega$$

The given circuit is now equivalent to the circuit shown in Fig. 2.22.

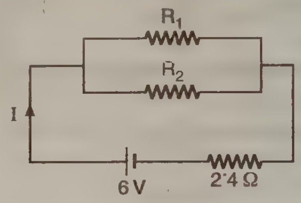

Fig. 2.22

It follows that the effective resistance of the circuit,

$$R = \frac{R_1 R_2}{R_1 + R_2} + 2{\cdot}4 = 3{\cdot}6 + 2{\cdot}4 = 6\ \Omega$$

Hence, current drawn by the circuit from the battery.

$$I = \frac{E}{R} = \frac{6}{6} = 1\ A$$

Problem 2.09. Four resistances 5, 50, 6 and 60 Ω are connected to the corresponding arms of the Wheatstone bridge. If a cell of e.m.f. 1·5 V and negligible internal resistance is connected across the bridge, calculate the current in arms and the cell. It is given that the bridge is in balanced position.

Sol. The four resistances 5, 50, 6, 60 Ω are connected as shown in the Fig. 2.23.

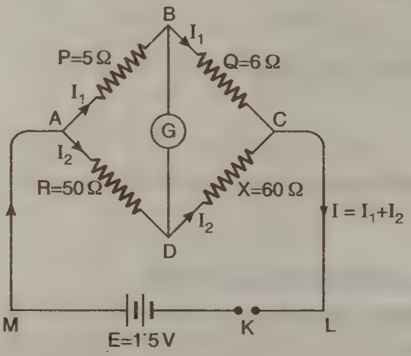

Fig. 2.23

For the given arrangement, it follows that $\frac{P}{Q} = \frac{R}{X}$. Therefore, Wheatstone bridge is in balanced state and hence no current flows through the galvanometer. Therefore, if at point A, current I_1 flows through P, the same will pass through Q and the remaining part of current I_2 that flows through R, will pass through X. From Kirchhoff's first law :

$$I = I_1 + I_2$$

Applying Kirchhoff's second law to the *closed part ABDA* :

$$I_1 \times 5 + (-I_2) \times 50 = 0 \quad \text{or} \quad I_1 - 10\, I_2 = 0$$

or $I_2 = \frac{I_1}{10}$

Applying Kirchhoff's second law to the *closed part ABCLMA :*

$$I_1 \times 5 + 6 \times I_1 = 1{\cdot}5 \quad \text{or} \quad 11\, I_1 = 1{\cdot}5$$

or $\mathbf{I_1 = 0{\cdot}1364\ A}$

∴ $I_2 = \frac{I_1}{10} = \frac{0{\cdot}1364}{10} = \mathbf{0{\cdot}0136\ A}$

Also, $I = I_1 + I_2 = 0{\cdot}1364 + 0{\cdot}0136 = \mathbf{0{\cdot}15\ A}$

ype C. On Slide wire bridge

Problem 2.10. A wire connected in the left gap of a etre bridge balances a 10 Ω resistance in the right gap at point, which divides the bridge wire in the ratio 3 : 2. alculate the resistance of the wire. If the length of the wire s 1 m, calculate the length of one ohm wire. *(Karnataka, 1987)*

Sol. Refer to Fig. 2.05. If R is resistance of the wire, then he wire of unknown resistance R is connected in the left gap nd a resistance X of 10 Ω is connected in the right gap. As he balance point divides the wire in the ratio 3 : 2, we have

$$\frac{P}{Q}=\frac{3}{2}$$

Now, $\frac{P}{Q}=\frac{R}{X}$ or $R = X\frac{P}{Q} = 10\times\frac{3}{2} = \mathbf{15\,\Omega}$

As the length of the wire is 1 m, therefore

$$\text{length of one ohm wire} = \frac{1}{15} = \mathbf{0\cdot067\ m}$$

Problem 2.11. With two resistance wires in the two gaps of a metre bridge, the balance point was found to be 1/3 m from the zero end. When a 6 Ω coil is connected in series with the smaller of the two resistances, the balance point is shifted to2 / 3m from the same end. Find the resistance of the two wires. *(Karnataka, 1986)*

Sol. Refer to Fig. 2.05. Let the two resistance wires be of values R_1 (in left gap) and R_2 (in right gap) respectively.

$$l=\frac{1}{3}\text{ m and } (100-l) = 1-\frac{1}{3}=\frac{2}{3}\text{ m}$$

$$\therefore\quad \frac{R_1}{R_2}=\frac{l}{(100-l)}=\frac{1/3}{2/3}=\frac{1}{2} \quad\text{or}\quad R_2 = 2\,R_1$$

On connecting 6 Ω coil :

Since resistance R_1 is smaller than R_2, 6 Ω coil has been connected in series to R_1. Therefore, resistance in the left gap becomes,

$$R_1' = R_1 + 6$$

Further, $l'=\frac{2}{3}$ and $(100-l')=1-\frac{2}{3}=\frac{1}{3}$ m

Again, $\frac{R'_1}{R_2}=\frac{l'}{(100-l')}$ or $\frac{R_1+6}{R_2}=\frac{2/3}{1/3}=2$

or $\frac{R_1+6}{2R_1}=2$

or $\mathbf{R_1 = 2\,\Omega}$

Also, $\mathbf{R_2 = 2\,R_1 = 2\times 2 = 4\,\Omega}$

Problem 2.12. Find the value of the unknown resistance X and the current drawn by the circuit from the battery, if no current flows through the galvanometer [Fig. 2.24]. Assume the resistance per unit length of the wire AB to be 0·01 Ω cm^{-1}. *(C.B.S.E. 2001)*

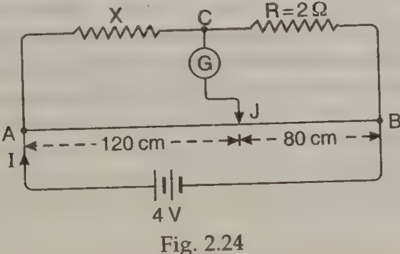

Fig. 2.24

Sol. Let P and Q be the resistances of the portions of wire AJ and JB respectively.

Then, $P = 120\times0{\cdot}01 = 1{\cdot}2\,\Omega$

and $Q = 80\times0{\cdot}01 = 0{\cdot}8\,\Omega$

Since the bridge is balanced,

$$\frac{X}{R}=\frac{P}{Q}\quad\text{or}\quad X = R\times\frac{P}{Q}$$

or $X=\frac{2\times1{\cdot}2}{0{\cdot}8}=\mathbf{3\,\Omega}$

As no current flows throgh galvanometer, the path between points C and J acts as an open path. Therefore, the given circuit is equivalent to the circuit drawn in Fig. 2.25.

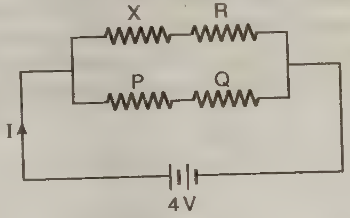

Fig. 2.25

Let R_1 be resistance of series combination of X and R and R_2 of the series combination of P and Q. Then,

$$R_1 = X + R = 3 + 2 = 5\,\Omega$$

and $R_2 = P + Q = 1{\cdot}2 + 0{\cdot}8 = 2\,\Omega$

Therefore, effective resistance of the circuit,

$$R' = \frac{R_1\,R_2}{R_1+R_2}=\frac{5\times2}{5+2}=\frac{10}{7}\,\Omega$$

Hence, current drawn by the circuit from the battery,

$$I=\frac{E}{R'}=\frac{4}{10/7}=\mathbf{2\cdot8\ A} \qquad (\because E = 4\text{ V})$$

Type D. On Potentiometer

Problem 2.13. The resistance of a potentiometer wire of length 10 m is 20 ohm. A resistance box and a 2 volt accumulator are connected in series with it. What resistance should be introduced in the box to have a potential drop of one microvolt per millimetre of the potentiometer wire ? *(Pre-degree Kerala, 1994)*

Sol. Here, resistance of potentiometer wire, R = 20 Ω

Required potential drop along the potentiometer wire

$$= 1\,\mu\text{V mm}^{-1} = (10^{-6}\text{ V})\times(10^{-3}\text{ m})^{-1} = 10^{-3}\text{ V m}^{-1}$$

Length of potentiometer wire, l = 10 m = 10^4 mm

Therefore, potential drop along the potentiometer wire,

$$V = 10\times10^{-3} = 10^{-2}\text{ V}$$

If I is current through the potentiometer wire, then

$$I=\frac{V}{R}=\frac{10^{-2}}{20}=5\times10^{-4}\text{ A}$$

If R′ is resistance that should be introduced in the resistance box, then

$$I=\frac{E}{R+R'}\quad\text{or}\quad 5\times10^{-4}=\frac{2}{20+R'}$$

or $\mathbf{R' = 3980\,\Omega}$

Problem 2.14. With a certain cell, the balance point is obtained at 65 cm from the end of a potentiometer wire. With another cell, whose e.m.f. differs from that of first by 0·1 V, the balance point is obtained at 60 cm. Find the e.m.f. of each cell. *(H.S.S.C.E. 2001)*

Sol. Let E_1 and E_2 be the e.m.fs. of two cells.

Here, balancing length for the first cell, l_1 = 65 cm and balancing length for the second cell, $l_2 = 60$ cm

Since balancing length for first cell is less than that for the second cell, the e.m.f. of second cell is less than that of first cell *i.e.* $E_2 < E_1$. As the e.m.f. of two cells differ by 0·1 V it follows that

$$E_2 = E_1 - 0{\cdot}1$$

Now, $$\frac{E_1}{E_2} = \frac{l_1}{l_2} \quad \text{or} \quad \frac{E_1}{E_1 - 0{\cdot}1} = \frac{65}{60}$$

or $$E_1 = 1{\cdot}3 \text{ V}$$

$\therefore$ $$E_2 = 1{\cdot}3 - 0{\cdot}1 = \mathbf{1{\cdot}2 \text{ V}}$$

Problem 2.15. Fig. 2.26 shows a 2·0 V potentiometer used for the determination of internal resistance of a 1·5 V cell. The balance point of the cell in open circuit is 76·3 cm. When a resistor of 9·5 Ω is used in the external circuit of the cell, the balance point shifts to 64·8 cm length of the potentiometer wire. Determine the internal resistance of the cell. *(Text Problem)*

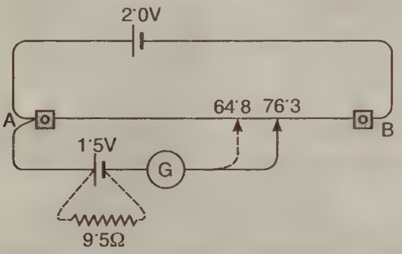

Fig. 2.26

Ans. Here, $S = 9{\cdot}5\ \Omega\ ;\ l_1 = 76{\cdot}3$ cm ; $l_2 = 64{\cdot}8$ cm

Now, $$r = \left(\frac{E}{V} - 1\right) \times S = \left(\frac{l_1}{l_2} - 1\right) \times S$$

$$= \left(\frac{76{\cdot}3}{64{\cdot}8} - 1\right) \times 9{\cdot}5 = \mathbf{1{\cdot}686\ \Omega}$$

Problem 2.16. A potentiometer wire of length 100 cm has a resistance of 10 Ω is connected in series with a resistance and a cell of e.m.f. 2 V of negligible internal resistance. A source of e.m.f. of 10 millivolt is balanced against a length of 40 cm of the potentiometer wire. What is the value of the external resistance ? *(I.I.T. 1976)*

Sol. The potentiometer wire of length 100 cm and resistance 10 Ω is connected to cell of e.m.f. 2 V and resistance R as shown in Fig. 2.27.

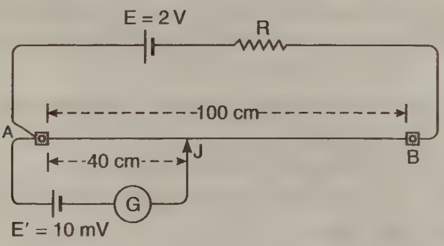

Fig. 2.27

If I is current through the potentiometer wire, then

$$I = \frac{E}{R+10} = \frac{2}{R+10} \qquad ...(i)$$

As the cell of e.m.f. E′ = 10 mV *i.e.* 10×10^{-3} V is balanced against a length of 40 cm of potentiometer wire, it follows that

$$I \times \text{resistance of 40 cm potentiometer wire} = 10 \times 10^{-3} \qquad ...(ii)$$

But resistance of 40 cm potentiometer wire

$$= \frac{10}{100} \times 40 = 4\ \Omega \qquad ...(iii)$$

Using equations (*i*) and (*iii*), equation (*ii*) becomes

$\therefore$ $$\frac{2}{R+10} \times 4 = 10 \times 10^{-3} \quad \text{or} \quad R + 10 = \frac{8}{10 \times 10^{-3}}$$

or $$R = \mathbf{790\ \Omega}$$

Problem 2.17. (*a*) If the galvanometer in the circuit shown in Fig. 2.28 reads zero, calculate the value of the resistor R, assuming that the 12 V source has negligible internal resistance.

(*b*) If cool air is blown across the wire-wound resistor, what effect will be noticed and why ? *(I.S.C.E. 1997)*

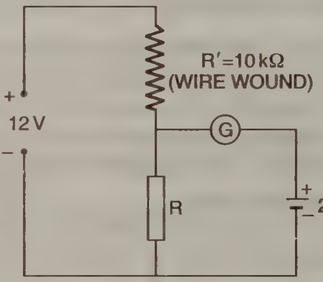

Fig. 2.28

Ans. (*a*) Here, e.m.f. of source battery, E = 12 V

Resistance of the wire wound resistor,

$$R' = 10\ \text{k}\Omega = 10 \times 10^3\ \Omega$$

Since the galvanometer connected in the circuit shows no deflection, the potential difference across the unknown resistance R is just equal to 2 V *i.e.* equal to the e.m.f. of cell connected across it. If I is current through the main circuit *i.e.* through series combination of resistor R and R′ connected to 12 V battery, then,

$$IR = 2 \qquad ...(i)$$

Also, $$I = \frac{E}{R+R'} = \frac{12}{R + 10 \times 10^3} \qquad ...(ii)$$

Substituting for I in equation (*i*), we have

$$\frac{12}{R + 10 \times 10^3} \times R = 2 \quad \text{or} \quad 6R = R + 10 \times 10^3$$

or $$R = 2 \times 10^3\ \Omega = \mathbf{2\ k\Omega}$$

(*b*) When current flows through a resistor, its temperature increases due to heat produced across it. If cool air is blown across the wire-wound resistor, its temperature will get lowered. Due to this, the resistance of the wire-wound resistor will decrease and current in the circuit will increase. As a consequence of it, the potential difference across the unknown resistor R will not remain 2 V. Since the e.m.f. of cell connected across R will no longer balance the potential drop across R, the galvanometer will show deflection.

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

roblem 2.18. 12 wires, each of resistance *r* ohm are onnected in the form of a skeleton cube. Find the ılent resistance of the cube, when the current enters corner and leaves at the diagonally opposite corner.

ol. Consider a skeleton cube ABCDEFGH made of 12 as shown in Fig. 2.29.

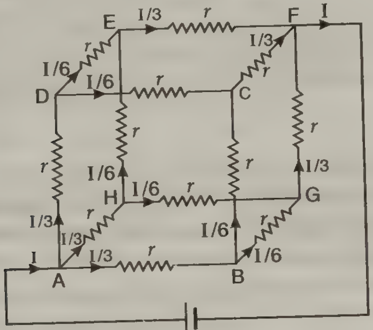

Fig. 2.29

n order to find its resistance, connect a battery of e.m.f. oss the diagonal corners A and F as shown in the figure. Suppose that current I enters the skeleton cube at the er A and leaves at the diagonally opposite corner F. The nt I will divide in three equal parts each equal to I/3 AB, AD and AH.

The current in AB, AD and AH will further divide along rent wires as explained below :

(*i*) The part I/3 flowing along AB will divide in two equal (I/6 each) along BC and BG.

(*ii*) The part I/3 flowing along AD will divide in two l parts (I/6 each) along DC and DE.

(*iii*) The part I/3 flowing along AH will divide in two l parts along HE and HG.

From the symmetry considerations, it follows that ent equal to I/3 should flow through in each of the three s CF, EF and GF, so that a net current equal to I may leave skeleton cube at the corner F.

Applying Kirchhoff's second law to the *closed part GFA of the circuit* :

E = P.D. across AB + P.D. across BG + P.D. across GF

$$E = \frac{I}{3}r + \frac{I}{6}r + r + \frac{I}{3}r = \frac{5I}{6}r \qquad ...(i)$$

If R is effective resistance of the skeleton cube, then

$$E = IR \qquad ...(ii)$$

From equations (*i*) and (*ii*), we have

$$IR = \frac{5I}{6}r \quad \text{or} \quad R = \frac{5}{6}r$$

Problem 2.19. 12 wires each of resistance *r* ohm are connected in the form of a skeleton cube. Find the uivalent resistance of the cube, when a cell is joined oss any one of the 12 wires forming the cube.

Sol. 12 wires each of resistance *r* ohm are connected in form of skeleton cube ABCDEFGH as shown in Fig. 2.30. order to find its resistance, connect a cell of e.m.f. E across wire AB, so that current I enters at corner A and leaves at B as shown in the figure.

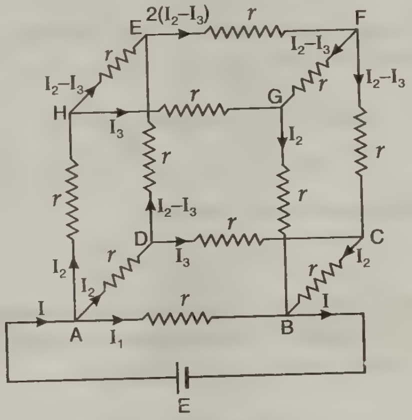

Fig. 2.30

Now, at point A, the current I will divide in three parts along AB, AD and AH and then following three different paths, it reaches point B. It follows that the resistances of the three paths between points A and B are not equal. However, the resistances of the paths followed by the current in reaching the point B through wire AD or AH are equal. Therefore, equal amounts of current will flow through wires AD and AH. Suppose that current I_1 flows along wire AB and current I_2 flows along each of the two wires AD and AH. Then, according to Kirchhoff's first law,

$$I = I_1 + I_2 + I_2$$

or

$$I = I_1 + 2I_2 \qquad ...(i)$$

Now, current I_2 through wire AD will again divide in two parts ; one part flowing along wire DC and then along wire CB ; while the other part reaches point B by flowing through wires DE, EF, FC and then through wire CB. As the above two paths are not of equal resistances, suppose that current I_3 flows through wire DC and the remaining part of the current $(I_2 - I_3)$ through wire DE. From symmetry considerations, it follows that current through wire HG will be I_3 and that through wire HE will be $(I_2 - I_3)$. The current through wire EF will become equal to $2(I_2 - I_3)$, which will then divide equally through wires FC and FG. The current through each of wire GB and CB will become I_2, so that at point B, current equal to $I_1 + I_2 + I_2$ *i.e.* $I_1 + 2I_2$ *i.e.* I will leave the skeleton cube.

For closed part EFGHE :

$$-I_3 r + (I_2 - I_3)r + 2(I_2 - I_3)r + (I_2 - I_3)r = 0$$

or

$$I_3 = \frac{4}{5}I_2$$

For closed part XADCBYX :

$$E = I_2 r + I_3 r + I_2 r = 2I_2 r + I_3 r \qquad ...(ii)$$

Using equation (*ii*), we have

$$E = 2I_2 r + \frac{4}{5}I_2 r = \frac{14}{5}I_2 r \qquad ...(iii)$$

For closed part XABYX :

$$E = I_1 r \qquad ...(iv)$$

From equations (*iii*) and (*iv*), we have

$$\frac{14}{5}I_2 r = I_1 r$$

or $I_2 = \frac{5}{14} I_1$

Substituting for I in equation (*i*), we have

$$I = I_1 + 2 \times \frac{5}{14} I_1 = \frac{12}{7} I_1 \qquad ...(v)$$

If R is equivalent resistance of the skeleton cube between points A and B, then

$$E = I R \qquad ...(vi)$$

From equations (*iv*) and (*vi*), we have

$$I R = I_1\, r \quad \text{or} \quad R = \frac{I_1}{I}\, r$$

Using equation (*v*), we have

$$R = I_1 \times \frac{7}{12 I_1}\, r = \frac{7}{12}\, r$$

Problem 2.20. Find the equivalent resistance betwen points X and Y of the network of resistors shown in Fig. 2.31. Each resistor is of resistance *r*.

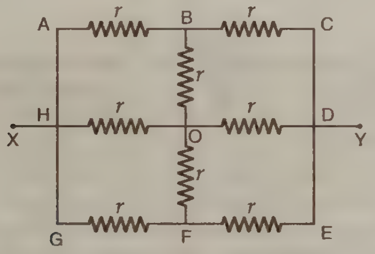

Fig. 2.31

Sol. Let R be equivalent resistance between points X and Y of the network of resistors shown in Fig. 2.31. To find R, connect a battery of e.m.f. E across the points X and Y as shown in Fig. 2.32.

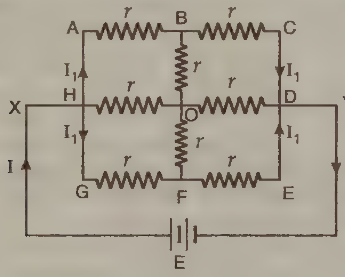

Fig. 2.32

Suppose that the network draws a current I from the battery. When the current I enters at point H, suppose that a part I_1 flows along path HAB. By symmetry, an equal current I_1 will flow along path HGF. According to Kirchhoff's first law, the remaining part $I - 2I_1$ will flow along path HO. Again by symmetry, the current I flowing out of point D will be composed of part I_1 from path BCD, part I_1 from path FED and $(I - 2I_1)$ from path OD. Applying Kirchhoff's first law, it follows that no current will flow along path BO or FO. Thus, resistances connected across paths BO and FO are ineffective and hence the circuit shown in Fig. 2.32 may be represented as shown in Fig. 2.33.

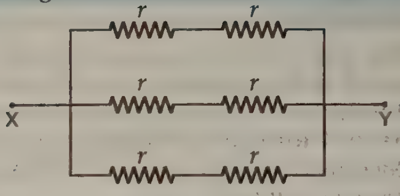

Fig. 2.33

The circuit is, now, equivalent to the pa combination of three equal resistors, each of resistan Therefore, resistance of the network between points X

$$R = \frac{2r}{3}$$

Problem 2.21. Eight equal resistors, each of resis *r* are connected along the edges of a pyramid OA having square base ABCD [Fig 2.34] Calculate the equiv resistance of the network between points A and B.

Sol. Let R be equivalent resistance between poi and B of the network of resistors shown in Fig. 2.34.

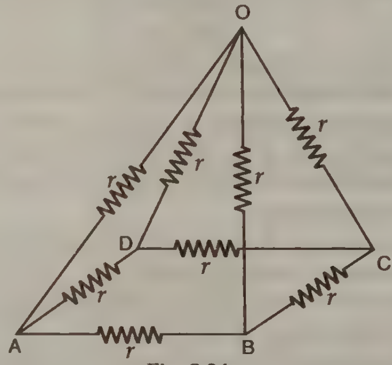

Fig. 2.34

In order to find R, connect a battery of e.m.f. E acro points A and B as shown in Fig. 2.35.

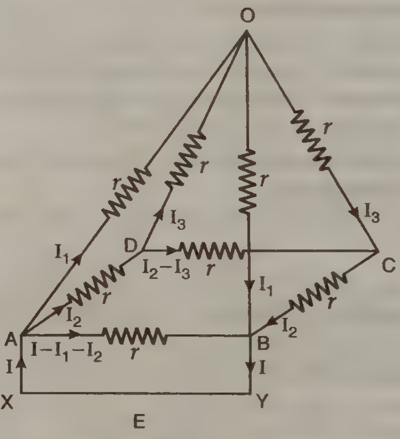

Fig. 2.35

If I is current drawn by the network from the ba then

$$R = \frac{E}{I}$$

ppose that when current I enters at point A, a part ; along path AO and another part I_2 along part AD. ccording to Kirchhoff's first law, the remaining part – I_2) will flow along path AB. By symmetry, the I flowing out from point B will be composed of part path OB, part I_2 from path CB and $(I - I_1 - I_2)$ from B. Also, when current I_2 enters at point D, if a part s along path DO, then remaining part $(I_2 - I_3)$ will ong path DC. Again, by symmetry, the current along C will be equal to I_3. The distribution of current in s branches of the circuit is as shown in the figure.

closed part ABOA of the circuit :

$$I_1 r + I_1 r - (I - I_1 - I_2) r = 0$$

$$3 I_1 + I_2 = I \qquad ...(ii)$$

closed part ADOA of the circuit :

$$I_1 r - I_2 r - I_3 r = 0$$

r $$I_1 - I_2 - I_3 = I \qquad ...(iii)$$

closed part CDOC of the circuit :

$$(I_2 - I_3) r - I_3 r - I_3 r = 0$$

r $$I_2 - 3 I_3 = 0 \quad \text{or} \quad I_3 = \frac{1}{3} I_2$$

ubstituting for I_3 in equation (*iii*), we get

$$I_1 - I_2 - \frac{1}{3} I_2 = 0 \quad \text{or} \quad I_1 = \frac{4}{3} I_2$$

ubstituting for I_1 in equation (*ii*), we get

$$3 \times \frac{4}{3} I_2 + I_2 = I \quad \text{or} \quad I_2 = \frac{1}{5} I$$

$$\therefore \quad I_1 = \frac{4}{3} I_2 = \frac{4}{3} \times \frac{1}{5} I = \frac{4}{15} I$$

n closed part ABYXA of the circuit :

$$E = (I - I_1 - I_2) r$$

Substituting for I_1 and I_2, we have

$$E = \left(I - \frac{4}{15} I - \frac{1}{5} I \right) r = \frac{8}{15} I r$$

or $$\frac{E}{I} = \frac{8}{15} r \qquad ...(iv)$$

From equation (*i*) and (*iv*), we have

$$R = \frac{8}{15} r$$

Problem 2.22. Find the equivalent resistance of the network of resistors shown in Fig. 2.36 between the ts X and Y.

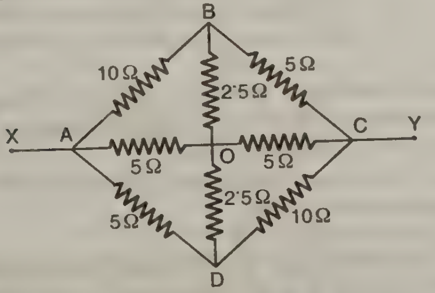

Fig. 2.36

Sol. Let R be equivalent resistance of the network of istors shown in Fig. 2.36. In order to find R, connect a battery of e.m.f E across the points X and Y as shown in Fig. 2.37.

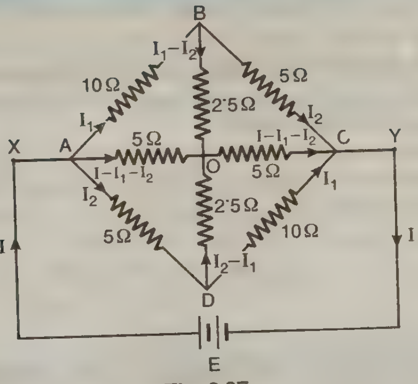

Fig. 2.37

If I is current drawn by the network from the battery, then

$$R = \frac{E}{I} \qquad ...(i)$$

Suppose that when current I enters at point A, a part I_1 flows along path AB and another part I_2 along AD. Then according to Kirchhoff's first law, the remaining part $(I - I_1 - I_2)$ will flow along path AO.

By symmetry, the current I flowing out from point C will be composed of part I_1 from path DC, part I_2 from path BC and $(I - I_1 - I_2)$ from path OC. Also, according to Kirchhoff's first law, the current along path BO will be $I_1 - I_2$ and that along path DO will be $I_2 - I_1$. The distribution of current in various branches of the circuit is as shown in the figure.

In closed part ABOA of the circuit :

$$I_1 \times 10 + (I_1 - I_2)\, 2{\cdot}5 - (I - I_1 - I_2) \times 5 = 0$$

or $$4 I_1 + (I_1 - I_2) - 2 (I - I_1 - I_2) = 0$$

or $$7 I_1 + I_2 = 2 I \qquad ...(ii)$$

In closed part BCOB of the circuit :

$$(I_1 - I_2) \times 2{\cdot}5 + (I - I_1 - I_2) \times 5 - I_2 \times 5 = 0$$

or $$(I_1 - I_2) + 2 (I - I_1 - I_2) - 2 I_2 = 0$$

or $$I_1 + 5 I_2 = 2 I \qquad ...(iii)$$

From equations (*ii*) and (*iii*), we have

$$7 I_1 + I_2 = I_1 + 5 I_2 \quad \text{or} \quad I_2 = \frac{3}{2} I_1$$

Substituting for I_2 in equation (*ii*), we get

$$7 I_1 + \frac{3}{2} I_1 = 2 I \quad \text{or} \quad I_1 = \frac{4}{17} I$$

Substituting for I_1 in equation (*ii*), we get

$$7 \times \frac{4}{17} I + I_2 = 2 I$$

or $$I_2 = \frac{6}{17} I$$

In closed part XADCYX of the circuit :

$$E = I_2 \times 5 + I_1 \times 10 = \frac{6}{17} I \times 5 + \frac{4}{17} I \times 10 = \frac{70}{17} I$$

or $$\frac{E}{I} = \frac{70}{17} \qquad ...(iv)$$

From equations (*i*) and (*iv*), we have

$$R = \frac{70}{17} = 4{\cdot}12\ \Omega$$

Problem 2.23. **(*a*) In a metre bridge, the balance point is found to be at 39·5 cm from the end A, when the resistor R is of 12·5 Ω [Fig. 2.05]. Determine the resistance of X. Why are the connections between resistors in a Wheatstone or metre bridge made of thick copper strips ?**

(*b*) Determine the balance point of the bridge above, if X and R are interchanged.

(*c*) What happens, if the galvanometer and cell are interchanged at the balance point of the bridge ? Would the galvanometer show any current ? (*Text Problem*)

Sol. (*a*) Here, $R = 12{\cdot}5\ \Omega\ ;\ l = 39{\cdot}5$ cm

Now, $$X = R\frac{(100-l)}{l} = \frac{12{\cdot}5\,(100-39{\cdot}5)}{39{\cdot}5}$$

$$= \frac{12{\cdot}5 \times 60{\cdot}5}{39{\cdot}5} = \mathbf{19{\cdot}15\ W}$$

Thick copper strips are used to minimise the resista of the strips, as the resistance of connecting copper strips not been accounted for in the formula.

(*b*) If X and R are interchanged, then

$$R = X\frac{(100-l)}{l}$$

$$\therefore \quad 12{\cdot}5 = 19{\cdot}15 \times \frac{(100-l)}{l}$$

or $\quad 12{\cdot}5\,l = 1915 - 19{\cdot}15\,l \quad$ or $\quad 31{\cdot}65\,l = 1915$

or $\quad \mathbf{l = 60{\cdot}5\ cm}$ (from end

(*c*) The galvanometer will **not** show any current

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 2.01. What is the loop rule ?

Ans. Kirchhoff's second law is also known as loop rule. For statement, refer to section 2.01.

Q. 2.02. Draw the circuit diagram of a Wheatstone bridge. (*H.S.S.C.E. 1997 S, 1995*)

Ans. For circuit diagram of Wheatstone bridge, refer to Fig. 2.03.

Q. 2.02. Why is a slide wire bridge also called a metre bridge ?

Ans. It is because, length of wire in a slide wire bridge is one metre.

Q. 2.04. What is principle of a metre bridge ? (*H.S.S.C.E. 1995*)

Ans. A metre bridge is based on Wheatstone bridge.

Q. 2.05. Why are the copper strips in a slide wire bridge made thick ?

Ans. In case, the copper strips are not thick, then their resistances have to be included in the respective ratio arms. In case, the strips are thick, their resistances can be safely ignored.

Q. 2.06. The resistance in the left gap of a metre bridge is 10 Ω and the balance point is 40 cm from the left end. Calculate the value of the unknown resistance.

Ans. Here, $l = 40$ cm ; $R = 10\ \Omega$

Now, $$X = R \times \frac{(100-l)}{l} = 10 \times \frac{100-40}{40}$$

$$= 10 \times \frac{60}{40} = \mathbf{15\ \Omega}$$

Q. 2.07. Name the device used for measuring the e.m.f. of a cell. (*C.B.S.E. 1996*)

Ans. A potentiometer (after calibration) can be used to measure the e.m.f. of a cell.

Q. 2.08. Why is a potentiometer named as potentiometer ?

Ans. Because, it is used to measure potential difference.

Q. 2.09. Describe the principle of a potentiometer. (*H.S.S.C.E. 2000 ; Pre-degree Kerala, 1991*)

Ans. For principle of potentiometer, refer to section 2.07.

Q. 2.10. The wire of a potentiometer should be of uniform area of cross-section. Why ?

Ans. If resistance per unit length of the wire is uniform, then fall of potential per unit length of the wire will also uniform, when constant current is passed through it. C then, it satisfies the requirement of the principle potentiometer.

Q. 2.11. Of which material is a potentiometer w normally made and why ? (*P.S.S.C.E. 19*

Ans. The potentiometer wire is made of an alloy, s as eureka or manganin. It is because, an alloy has h resistivity and a low value of temperature coefficien resistance.

Q. 2.12. What type of cell should be used in the m circuit of the potentiometer and why ?

Ans. A Leclanche cell should be used in the main cir of the potentiometer. This is because of the fact that Leclan cell is useful, when the current is drawn for a short tim

Q. 2.13. In a potentiometer arrangement, a cell of e. 1·25 V gives a balance point at 35·0 cm length of the w If the cell is replaced by another cell and the balance p shifts to 63·0 cm, what is the e.m.f. of the second cell (*Text Quest*

Ans. Here, $E_1 = 1{\cdot}25$ V ; $l_1 = 35{\cdot}0$ cm ; $l_2 = 63{\cdot}0$ cm

Now, $$\frac{E_1}{E_2} = \frac{l_1}{l_2}$$

or $$E_2 = E_1 \times \frac{l_2}{l_1} = 1{\cdot}25 \times \frac{63{\cdot}0}{35{\cdot}0} = \mathbf{2{\cdot}25\ V}$$

Q. 2.14. Sometimes balance point may not be obtai on the potentiometer wire. Why ?

Ans. The balance point may not be obtained on potentiometer wire, in case the e.m.f. of the auxiliary bat (battery used to maintain constant current through potentiometer wire) is less than the e.m.f. of the cell to measured.

Q. 2.15. The e.m.f. of the cell used in the main cir of the potentiometer should be more than the poten difference to be measured. Why ?

Ans. If it is not so, the balance point will not be obtai on the potentiometer wire.

Also, refer to VSQ 2.14.

Q. 2.16. Name the device used for measuring internal resistance of a secondary cell. (*C.B.S.E. 19*

Ans. A potentiometer can be used to measure internal resistance of a secondary cell.

Q. 2.17. Write down the relation between the e.m. a cell and its internal resistance. (*I.S.C.E. 19* ns. The relation between e.m.f. and internal resistance ell is given by

$$r = \left(\frac{E - V}{V}\right) \times S,$$

where V is terminal potential difference between the two poles of the cell on connecting a resistance S across it.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 2.01. State Kirchhoff's laws.

(H.S.S.C.E. 1995 ; I.S.C.E. 1995)

Or

State Kirchhoff's rules for electrical network.

(H.S.S.C.E. 2002, 2001 ; C.B.S.E. 1996)

Ans. For statement of Kirchhoff's laws, refer to section

Q. 2.02. Explain the significance of Kirchhoff's law.

(P.S.S.C.E. 1992)

Ans. Ohm's law can be used only to analyse simple rical circuits. When the circuit contains more than one ce of e.m.f. and the distribution of current in various ches of the circuit is quite complicated, then one is unable alyse such a circuit by making use of Ohm's law. In such e, Kirchhoff's laws are used to analyse the circuit.

Q. 2.03. Find out the magnitude of resistance X in the it shown in Fig. 2.38, when no current flows through Ω resistor. *(I.S.C.E. 1998)*

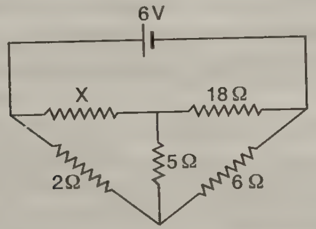

Fig. 2.38

Ans. Since no current flows through the 5 Ω resistor, the uit represents a balanced wheatstone bridge.

$$\therefore \quad \frac{X}{18} = \frac{2}{6} \quad \text{or} \quad X = \frac{2}{6} \times 18 = 6\,\Omega$$

Q. 2.04. What is the resistance between points A and n the circuit shown in Fig. 2.39 ? *(I.S.C.E. 1994)*

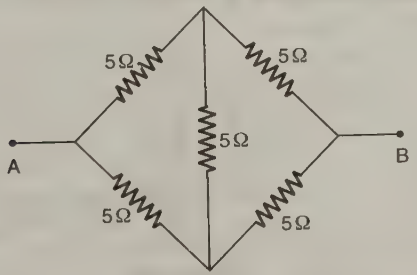

Fig. 2.39

Ans. The network represents a balanced Wheatstone idge and hence the resistance of 5 Ω connected across the idge can be considered as an open path. As such, the twork is equivalent to the circuit drawn in Fig. 2.40.

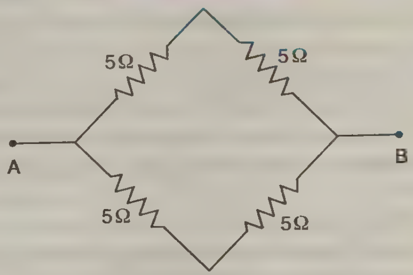

Fig. 2.40

The network is now a parallel combination of two resistive paths. The resistance of each resistive path is 5 + 5 *i.e.* 10 Ω. Hence, net resistance between points A and B,

$$\frac{1}{R} = \frac{1}{10} + \frac{1}{10} = \frac{1}{5} \quad \text{or} \quad R = 5\,\Omega$$

Q. 2.05. The wire AB of a slide wire bridge shown in Fig. 2.41 is 400 cm long. Where should the free end of the galvanometer be connected on AB, so that the galvanometer shows zero deflection ? *(C.B.S.E. 1997)*

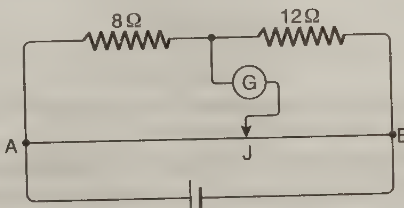

Fig. 2.41

Ans. Suppose that the galvanometer shows zero deflection, when the free end of the galvanometer is connected at point J. If length of the portion of wire AJ = l, then

$$JB = 400 - l$$

Since the bridge is balanced, we have

$$\frac{l}{400 - l} = \frac{8}{12} \quad \text{or} \quad l = 160 \text{ cm}$$

Q. 2.06. The variation of potential difference V with length *l* in case of two potentiometers X and Y is as shown in the Fig. 2.42. Which one of these two will you prefer for comparing e.m.fs. of two cells and why ? *(C.B.S.E. 1997)*

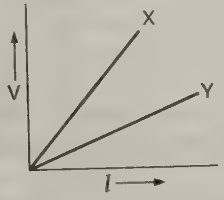

Fig. 2.42

Ans. A potentiometer is said to be more sensitive, if fall of potential per unit length along the wire *i.e.* potential gradient $\left(\frac{dV}{dl}\right)$ is small. The slope of V – l graph *i.e.* $\frac{dV}{dl}$ is smaller for wire Y than that for wire X. Therefore, potentiometer using wire Y will be preferred for comparing e.m.fs. of two cells.

Q. 2.07. How can you make a potentiometer of given wire length more sensitive using a resistance box ? *(H.S.S.C.E. 1994)*

Ans. When resistance is introduced by using a resistance box, the current passing through the potentiometer wire decreases. It results in lesser value of fall of potential per unit length of the wire *i.e.* lesser value of the least count.

Q. 2.08. Draw circuit diagram for the comparison of e..m.fs. of two cells with the help of a potentiometer. *(H.S.S.C.E. 2002)*

Sol. Refer to Fig. 2.07.

Q. 2.09. Draw the circuit diagram of a potentiometer for using it to find the internal resistance of a cell. *(H.S.S.C.E. 2001, P.S.S.C.E. 1998)*

Ans. Refer to Fig. 2.08.

Q. 2.10. In the circuit shown in Fig. 2.43, AB is a resistance wire of uniform cross-section in which a potential gradient of 0·01 V cm^{-1} exists.

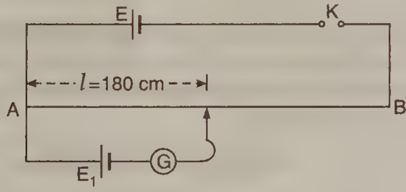

Fig. 2.43

(*i*) If the galvanometer G shows zero deflection, what is the e.m.f. E_1 of the cell used ?

(*ii*) If the internal resistance of the driver cell increases on some account, how will it change the balance point in the experiment ? *(C.B.S.E. 1998 S)*

Ans. (*i*) E_1 = potential drop across wire AJ

$= 180 \times 0{\cdot}01 = \mathbf{1{\cdot}8\ V}$

(*ii*) When the internal resistance of the driver cell increases, the current through wire AB and hence potential gradient along wire AB will decrease.

As such, the cell of e.m.f. E_1 (=1·8 V) will be bala across a length greater than 180 cm *i.e.* balance point J will towards right.

Q. 2.11. A cell of e.m.f. 4 V and of negligible int resistance is connected in series with a potentiometer of length 400 cm. The e.m.f. of Leclanche cell is four balance on 150 cm of the potentiometer wire. Find the e of the Leclanche cell. *(Karnataka, 19*

Ans. The fall of potential per unit length of pote meter wire $= \frac{4}{400} = 10^{-2}$ V cm^{-1}

Since Leclanche cell is found to be balanced ag 150 cm of potentiometer wire,

∴ the e.m.f. of Leclanche cell $= 150 \times 10^{-2} = \mathbf{1{\cdot}5\ V}$

Q. 2.12. Why do we prefer a potentiometer w longer bridge wire ? *(C.B.S.E.*

Ans. The smallest potential difference, which a p tiometer can measure gives the sensitivity of the pote meter. Therefore, for a potentiometer to be more sensitiv potential drop per unit length of its wire should be as s as possible. Obviously, if a potentiometer has a longer b wire, the potential drop per unit length will be lesser hence such a potentiometer will be able to measure very s potential differences.

Q. 2.13. In what respect is the potentiometer b than a moving coil voltmeter in comparing the e.m. two cells ? *(H.S.S.C.E. 2*

Or

Why is the use of a potentiometer preferred over of a voltmeter for measurement of e.m.f. of a cell ? *(C.B.S.E. 1998,*

Ans. When a voltmeter is connected across the two of a cell, it draws a small current from the cell. As a re the voltmeter measures terminal potential difference bet the two poles of the cell, which is always less than e.m the cell.

On the other hand, when a potentiometer is used fo measurement of e.m.f. of a cell, it does not draw any cu from the cell. Hence, it measures e.m.f. of the cell. For reasons, a potentiometer is preferred over a voltmete measuring e.m.f. of a cell.

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For **a**mbitious, **b**rilliant & **c**urious Students

Q. 2.01. If each of the resistances in network shown in Fig. 2.44 is *r*, what is the resistance between terminals A and B ? *(H.S.S.C.E. 2001 ; H.P.S.S.C.E. 1995 ; I.I.T. 1978)*

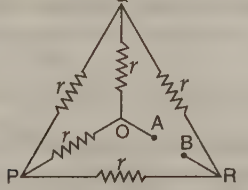

Fig. 2.44

Ans. The given network can be redrawn as shown in Fig. 2.45. It represents a balanced Wheatstone bridge *i.e.* if a source of e.m.f. is connected across terminals A and B, no curren flow along the path PQ. Therefore, the path PQ in the net is equivalent to an open path and the given network ca represented as shown in Fig. 2.46.

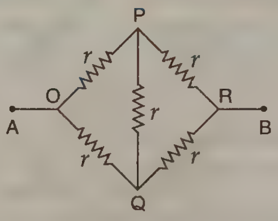

Fig. 2.45

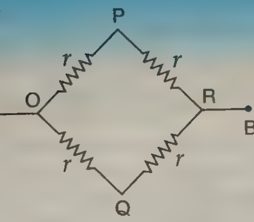

Fig. 2.46

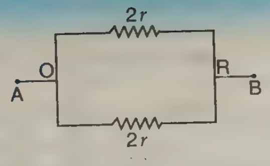

Fig. 2.47

The resistance of each of the two paths PR and QR is $2r$ own in Fig. 2.47. If R is the resistance of the network een terminals A and B, then

$$\frac{1}{R}=\frac{1}{2r}+\frac{1}{2r}=\frac{1}{r} \quad \text{or} \quad R=r$$

Q. 2.02. In the circuit shown in Fig. 2.48, the resistances P and R are unequal. If the reading of the galvano- r remains the same with switch S open or closed, then is the value of current through galvanometer ? *(I.I.T. 1999)*

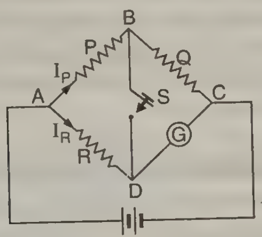

Fig. 2.48

Ans. Since the closing or opening of the switch S does affect the reading of the galvanometer, the points B and e at same electric potential. The current I_P flows as such ugh the resistance Q, while the current I_R flows through galvanometer. Thus, the current through the anometer is equal to I_R.

Q. 2.03. A battery of e.m.f. 9 V and negligible internal resistance is connected to a 3 kΩ resistor. The potential p across a part of the resistor (between points A and B) easured by (*a*) a 20 kΩ voltmeter [Fig. 2.49], (*b*) a 1 kΩ tmeter [Fig. 2.50]. In (*c*) both the voltmeters are nected across AB [Fig. 2.51].

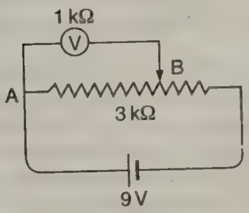

Fig. 2.49

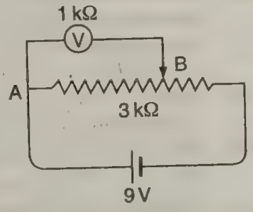

Fig. 2.50

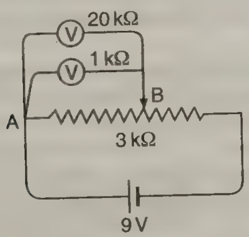

Fig. 2.51

In which case would you get the (*i*) highest, (*ii*) lowest ading ?

Ans. The voltmeter, which will draw minimum current (so that potential difference across AB will decrease by a minimum amount), will give the highest reading.

In case (*a*), $R_V = 20\ \text{k}\Omega$

In case (*b*), $R_V = 1\ \text{k}\Omega$

In case (*c*), $\frac{1}{R_V}=\frac{1}{20}+\frac{1}{1}=\frac{1+20}{20}$ or $R_V=\frac{20}{21}\ \text{k}\Omega$

(*i*) Since in case (*a*), the resistance of voltmeter is maximum (20 kΩ) ; it will draw minimum current and hence will give maximum reading.

(*ii*) Since in case (*c*), R_V is minimum $\left(\frac{20}{21}\ \text{k}\Omega\right)$, it will give lowest reading.

Q. 2.04. Fig. 2.52 shows a potentiometer circuit for comparison of two resistances. The balance point with a standard resistor R = 10 Ω is found to be 58·3 cm, while that with the unknown resistance X is 68·5 cm. (*a*) Determine the value of X. (*b*) What would you do, if you failed to find a balance point with the given cell E ? *(Text Question)*

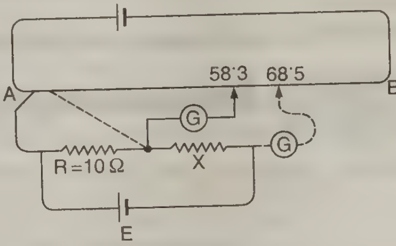

Fig. 2.52

Ans. (*a*) Let E_1 and E_2 be potential drops across R and X respectively.

Obviously, $\frac{E_2}{E_1}=\frac{X}{R}$

or $X=\left(\frac{E_2}{E_1}\right)R=\left(\frac{l_2}{l_1}\right)R$

Here, $R = 10\ \Omega$; $l_1 = 58{\cdot}3$ cm and $l_2 = 68{\cdot}5$ cm

$\therefore$ $X=\frac{68{\cdot}5}{58{\cdot}3}\times 10 = \mathbf{11{\cdot}75\ \Omega}$

(*b*) We fail to get balance point with the given cell of e.m.f. E, if potential drop across R or X is greater than the potential difference across the wire AB. In order to obtain the balance point, either a suitable **resistance should be put in series with R and X** (so as to decrease current through wire AB and hence to decrease potential drop across the wire) or **a cell of lesser e.m.f. should be used.**

Q. 2.05. Fig. 2.53. shows a potentiometer with a cell of 2·0 V and internal resistance 0·4 Ω maintaining a potential drop across the resistor wire AB. A standard cell which maintains a constant e.m.f. E_1 = 1·02 V (for very moderate currents up to a few ampere) gives a balance point at 67·3 cm length of the wire. To ensure very low currents drawn from the standard cell, a very high resistance of 600 kΩ is put in series with it, which is shorted close to the balance point. The standard cell is then replaced by a cell of unknown e.m.f. E_2 and the balance point found similarly turns out to be at 82·3 cm length of the wire.

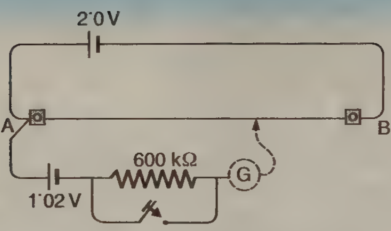

Fig. 2.53

(a) What is the value of E_2 ?

(b) What purpose does the high resistance of 600 kΩ have ?

(c) Is the balance point affected by this high resistance ?

(d) Is the balance point affected by the internal resistance of the driver cell ?

(e) Would the method work in the above situation, if the driver cell of the potentiometer had an e.m.f. of 1·0 V instead of 2·0 V ?

(f) Would the circuit work well for determining extremely small e.m.f., say of the order of a few mV as the typical e.m.f. of a thermocouple) ? (*Text Ques*

Ans. (*a*) Here, $l_1 = 67{\cdot}3$ cm ; $l_2 = 82{\cdot}3$ cm ; $E_1 = 1{\cdot}0$

Now, $$\frac{E_2}{E_1} = \frac{l_2}{l_1}$$

or $$E_2 = \frac{l_2}{l_1} \times E_1 = \frac{82{\cdot}3}{67{\cdot}3} \times 1{\cdot}02$$

$$= \mathbf{1{\cdot}247\ V}$$

(*b*) The purpose of using high resistance is to **allow a very small current** to flow through the galvanometer, the balance point has not been obtained.

(*c*) No, the balance point is **not** affected by the pre of high resistance.

(*d*) No, the balance point is **not** affected by the int resistance of the driver cell.

(*e*) No, the arrangement will **not** work. If the e.m.f. driver cell is less than that of the cell whose e.m.f. is found, the balance point will not be obtained.

(*f*) The circuit is **not** suitable for measuring extre small e.m.f. It is because in such a case, the balance poin be just close to the end A.

18. With the help of a circuit diagram ; explain h potentiometer can be used to compare e.m.fs. of twc State the formula used. (*H.S.S.C.E. 2002 ; C.B.S.E. 2000 ; H.P.S.S.C.E.*
19. Explain, how you will compare the e.m.fs.' of two ce a potentiometer. (*C.B.S.E.*
20. Draw a circuit diagram and explain how the e.m the two primary cells can be compared by us potentiometer ? State the formula used. (*C.B.S.E. 2000,*
21. Define e.m.f. of a cell. Explain how the internal resis of a primary cell can be determined using a potentior (*P.S.S.C.E.*
22. Explain, with the help of a circuit diagram, the u potentiometer for determination of internal resistar a primary cell. Derive the necessary mathem expression. (*C.B.S.E. 1999, 1998 ; H.P.S.S.C.E.*
23. Give the principle of a potentiometer. Explain hov you use it to measure the internal resistance of a ce (*P.S.S.C.E. 1999 S ; H.S.S.C.E. 1*
24. With the help of a circuit diagram, explain how the in resistance of a cell can be determined usi potentiometer. Write the formula used. (*H.S.S.C.E. 2002 ; C.B.S.E. 2000,*

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

State and explain Kirchhoff's laws. Derive the condition for obtaining balance in a Wheatstone bridge.
(H.P.S.S.C.E. 2000 ; P.S.S.C.E. 2000 ; C.B.S.E. 1990)

State Kirchhoff's laws of electric circuits and using these laws, derive Wheatstone bridge principle ?
(P.S.S.C.E. 2002, 2001)

What is Wheatstone bridge ? Derive the condition for balance of a Wheatstone bridge. How does it form the principle of a slide wire bridge ? Draw a circuit diagram to compare two resistances with the help of a slide wire bridge.

4. Describe the principle and construction of potentiometer. Explain, how a potentiometer can be used to compare the e.m.fs. of two cells. *(P.S.S.C.E. 2002)*

5. Give the principle of a potentiometer. Explain, how will you use a potentiometer to (*i*) measure the internal resistance of a cell and (*ii*) to compare the e.m.fs. of two cells.

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

A. On Kirchhoff's laws

Fig. 2.54 shows a part of an electric current consisting of resistors of resistances r, $2r$ and $3r$. The potentials at the points A, B and C are 3 E, 2 E and E respectively. Find the potential at point O. Also, find the value of currents I_1, I_2 and I_3.

$$\left[\textbf{Ans. } \frac{26\,E}{11};\ I_1=\frac{7\,E}{11\,r};\ I_2=\frac{2\,E}{11\,r};\ I_3=\frac{5\,E}{11\,r}\right]$$

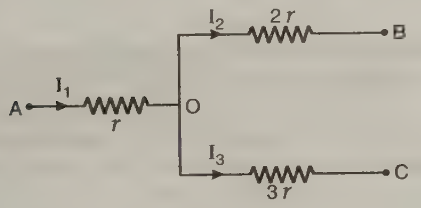

Fig. 2.54

Two cells of e.m.f. $E_1 = 1{\cdot}5$ V and $E_2 = 2{\cdot}0$ V and internal resistance of $r_1 = 1{\cdot}0\ \Omega$ and $r_2 = 1{\cdot}5\ \Omega$ respectively are connected to an external resistance of 2·5 Ω as shown in Fig. 2.55. Find the current in the circuit and the potential difference between points B and C. **[Ans. 0·1 A, 1·85 V]**

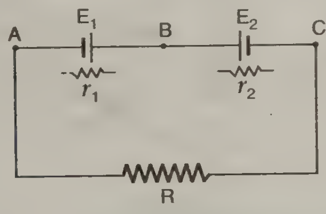

Fig. 2.55

3. In the circuit given in Fig. 2.56, find the potential difference between the points A and B. Assume that both the batteries have zero internal resistance. **[Ans. 9·6 V]**

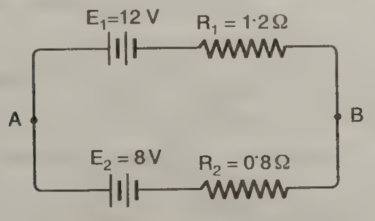

Fig. 2.56

4. In the network shown in the Fig. 2.57 :

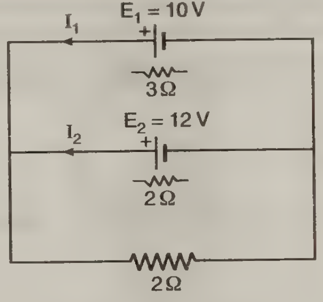

Fig. 2.57

(*i*) What is current in 2 Ω resistor ?

(*ii*) What is terminal voltage of each battery ?

[Ans. (*i*) 3·5 A ; (*ii*) across E_1 or E_2 = 7 V**]**

5. The circuit diagram shown in Fig. 2.58 has two cells E_1 and E_2 with e.m.f. 4 V and 2 V respectively, each one having an internal resistance 2 Ω. The external resistance R is of 8 Ω. Find the magnitude and direction of the currents flowing through the two cells. *(I.S.C.E. 1998)*

[Ans. $I_1 = 2/3$ A, $I_2 = -1/3$ A**]**

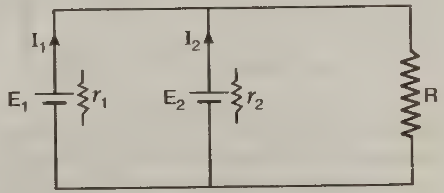

Fig. 2.58

6. Using Kirchhoff's laws, determine the currents I_1, I_2 and I_3 for the network shown in Fig. 2.59. *(C.B.S.E. 1999 S)*

[Ans. $I_1 = 3$ A, $I_2 = -1{\cdot}5$ A, $I_3 = 4{\cdot}5$ A**]**

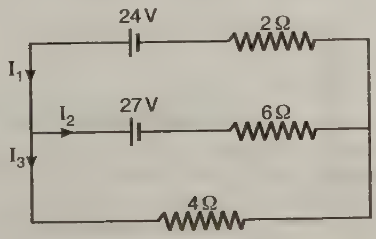

Fig. 2.59

7. A cell of e.m.f. E_1 (= 2 V) and internal resistance 1 Ω is connected in parallel with another cell of e.m.f. E_2 (= 1·5 V) and internal resistance 2 Ω. When the combination is in parallel with a resistance of 4 Ω, find the current through each branch and also the potential difference across the 4 Ω resistance. *(Karnataka, 1990)*

$$\left[\textbf{Ans. } I_1 = \frac{3}{7}\text{ A}, I_2 = -\frac{1}{28}\text{ A}; I = \frac{11}{28}\text{ A}; \frac{11}{7}\text{ V}\right]$$

8. Two cells of e.m.fs. 6 V and 12 V and internal resistances 1 Ω and 2 Ω respectively are connected in parallel so as to send current in the same direction through an external resistance of 15 Ω. Draw the circuit diagram. Using Kirchhoff's laws, calculate : (*i*) current through each branch of two circuit, (*ii*) potential difference across the 15 Ω resistance. *(H.S.S.C.E. 2002)*

[**Ans.** (*i*) I_1 due to 6 V cell) = – 1·66 A, I_2 (due to 12 V cell) = 2·17 A, I (through 15 Ω) = 0·51 A (*ii*) 7·65 V)

9. Find the currents through all the arms in the network shown in Fig. 2.60 of a cell and resistances.

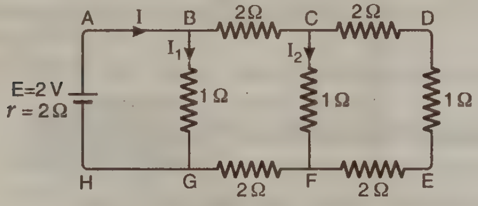

Fig. 2.60

$$\left[\textbf{Ans. } I = \frac{70}{99}\text{ A}; I_1 = \frac{58}{99}\text{ A}; I_2 = \frac{10}{99}\text{ A}; I_{BC} = I_{FG} = \frac{-12}{99}\text{ A}\right.$$

$$\left.\text{and } I_{CD} = I_{DE} = I_{EF} = \frac{2}{99}\text{ A}\right]$$

10. In the circuit shown in Fig. 2.61, find the current through 4 Ω resistor. *(I.I.T. 1998)* [**Ans.** 0·25 A]

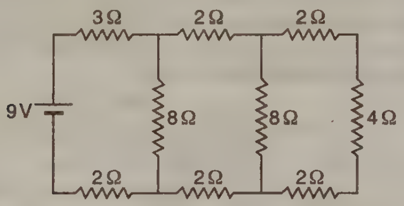

Fig. 2.61

11. Two cells of e.m.f. of 1· 6 V and 2·4 V have internal resistance 2 Ω and 4 Ω respectively. The two positive poles are connected to resistance of 6 Ω and negative poles connected to 8 Ω coil. If another wire of 10 Ω is connected between the mid-points of these wires, what is the potential difference across it. *(Karnataka, 1984)* [**Ans.** 1·31 V]

12. In the network shown in the Fig. 2.62 :

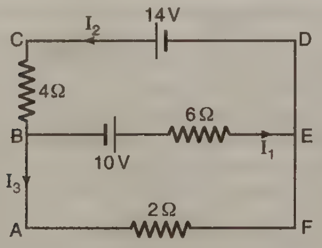

Fig. 2.62

(*i*) Find the current I_1, I_2 and I_3.

(*ii*) Find the potential difference between points B and E.

[**Ans.** (*i*) I_1 = 2 A, I_2 = 3 A, I_3 = 1 A ; (*ii*) 2 V]

13. Find the current in the three resistors shown in Fig.

[**Ans.** Zero in each resista

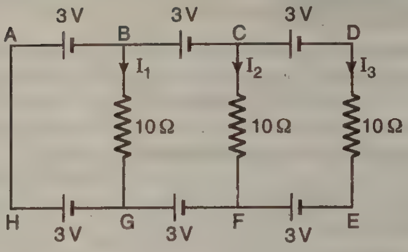

Fig. 2.63

14. In the network, given in the Fig. 2.64 :

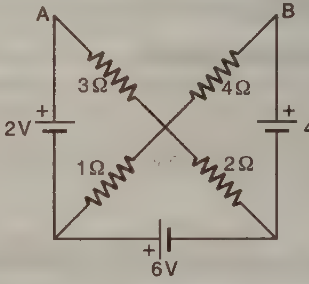

Fig. 2.64

(*i*) Calculate the current through the 6 V battery.

(*ii*) Determine the potential difference between points A B. [**Ans.** (*i*) 1·3 A ; (*ii*)

15. Determine the values of currents I_1, I_2 and I_3 in the netw shown in Fig. 2.65. Given that $R_1 = R_2 = 2\ \Omega$, $R_3 = 1\ \Omega$, $R_5 = 4\ \Omega$, $E_1 = 5$ V and $E_2 = 10$ V.

[**Ans.** $I_1 = I_3 = 1{\cdot}875$ A, $I_2 = 2$

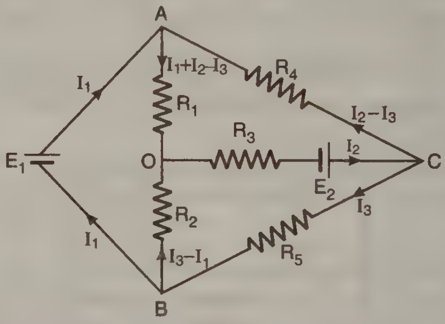

Fig. 2.65

Type B. On Wheatstone Bridge

16. Five resistances are connected as shown in Fig. 2.66. W is the effective resistance between points X and Y ? *(H.S.S.C.E. 1996)* [**Ans.** 3·33 c

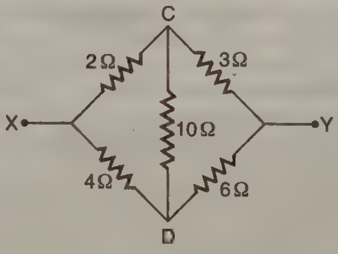

Fig. 2.66

7. Calculate the resistance between points X and Y in the circuit shown in the Fig. 2.67. **[Ans. 8 Ω]**

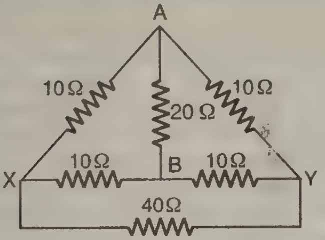

Fig. 2.67

3. Find the equivalent resistance of the network shown in Fig. 2.68 between points X and Y. **[Ans. 10 Ω]**

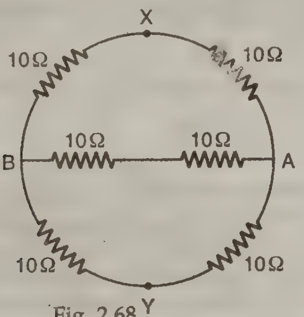

Fig. 2.68

9. Six equal resistors, each of 5 Ω are connected to a battery of e.m.f. 3 V as shown in Fig. 2.69. What is the current drawn by the circuit from the battery ? **[Ans. 1·2 A]**

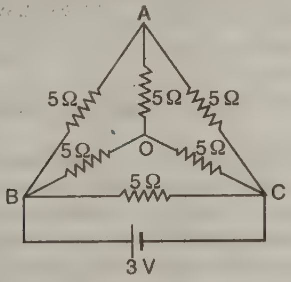

Fig. 2.69

0. For the network shown in the Fig. 2.70, determine the value of R and the current through it, if the current through the branch AO is zero. **[Ans. 6 Ω, 0·5 A]**

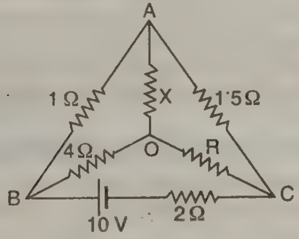

Fig. 2.70

1. Five equal resistors, each of 2 Ω, are connected in a network as shown in Fig. 2.71. Find the equivalent resistance between points X and Y. (*H.S.S.C.E. 1999 S*) **[Ans. 2 Ω]**

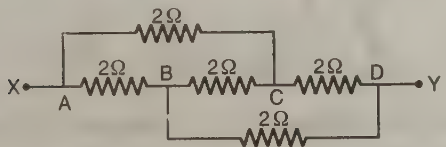

Fig. 2.71

22. Calculate the current drawn by the network of resistors from the battery as shown in Fig. 2.72. **[Ans. 2 A]**

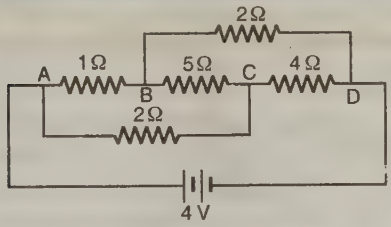

Fig. 2.72

23. In a Wheatstone's bridge network, resistances P = 3 Ω, Q = 2 Ω, R = 6 Ω, S = 4 Ω and the galvanometer resistance G = 5 Ω. Calculate the currents in different branches of the network. E.M.F. of the cell is 2 V. Ignore internal resistance of the cell (*H.S.S.C.E. 2002*)
[Ans. I = 0·6 A ; $I_P = I_Q$ = 0·4 A, $I_R = I_S$ = 0·2 A, I_G = 0]

24. In the circuit shown in Fig. 2.73, find the currents I, I_1, I_2 and I_3. Given that e.m.f. of the battery = 2 V, internal resistance of the battery = 2 Ω and resistance of the galvanometer = 4 Ω. **[Ans. I = 47/91 A, I_1 = 17/91 A, I_2 = 30/91 A, I_3 = − 1/91 A]**

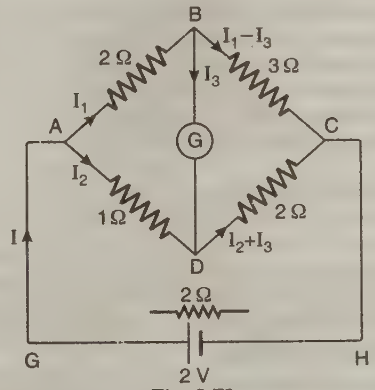

Fig. 2.73

25. Determine the current in each branch of the network as shown in the Fig. 2.74. **[Ans. I = 10/17 A, I_1 = 4/17 A, I_2 = 6/17 A, I_3 = − 2/17 A, I_4 = 6/17 A, I_5 = 4/17 A]**

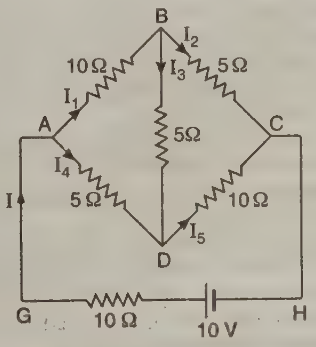

Fig. 2.74

Type C. On Slide wire Bridge

26. Two parallel resistors of 5 ohm and 20 ohm are connected in left arm of a metre bridge. If the null point is at 40 cm from left end of the wire, calculate the value of resistance connected in right arm. **[Ans. 6 Ω]**

27. In the circuit shown in Fig. 2.75, a metre bridge is shown in its balanced state. The metre bridge has a resistance of 1 Ω cm^{-1}. Calculate the value of the unknown resistance X and the current drawn from the battery of e.m.f. 6 V and

negligible internal resistance. (*C.B.S.E. 1996*)
[**Ans.** 2 Ω, 1·26 A]

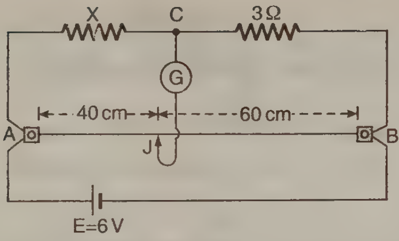

Fig. 2.75

28. In a slide wire bridge, when a resistor of resistance 2 Ω is in left gap and unknown resistance in right gap, the balance point is obtained at 40 cm from the zero end of the wire. Find the shift in the balance point, when the unknown resistor is shunted with a resistor of 2 Ω.
[**Ans.** 22·5 cm]

29. In a metre bridge experiment, resistors of resistance 5 Ω and 2 Ω are connected in the left and right gap respectively. When the resistor of 5 Ω is shunted by a wire, the balance point is found at 62·5 cm mark. What is the resistance of the wire ? [**Ans.** 10 Ω]

30. In a metre bridge experiment, a resistance R is kept in the right gap in all the observations. When resistances R_1 and R_2 are connected in trun in the left gap, the balance point is obtained at 40 cm and 50 cm from the zero end of the wire. Find the position of balance point, when the left gap contains R_1 and R_2 (*a*) in series and (*b*) in parallel.
[**Ans.** (*a*) 62·5 cm (*b*) 28·6 cm]

31. In comparing the resistance of two coils P and Q with a metre bridge, the balance point is obtained at 30 cm from the zero end. The coils P and Q are interchanged and the balance point is obained at 120 cm from the zero end. Find (*a*) the ratio of the resistance of the two coils and (*b*) the length of the bridge wire. [**Ans.** (*a*) 1 : 4 (*b*) 150 cm]

Type D. On Potentiometer

32. A cell gives a balance with 85 cm of a potentiometer wire. When the terminals of the cell are shorted through a resistance of 7·5 Ω, the balance is obtained at 75 cm. Find the internal resistance of the cell. (*I.S.C.E. 1995*)
[**Ans.** 1 Ω]

33. It is found that 125 cm length of a potentiometer wire is required to balance the e.m.f. of a Daniel cell but that only 100 cm of the wire is required for the balance, if the poles of the cell are joined to a resistance of 2 ohm. Calculate the internal resistance of the cell. [**Ans.** 0·5 ohm]

34. A cell can be balanced against 110 cm and 100 cm of potentiometer wire respectively, when open circuited and when short circuited through a resistance of 10 ohm. Find the internal resistance of the cell. [**Ans.** 1 Ω]

35. In an experiment to determine the internal resistance of a cell, the null point is obtained at 220 cm, when the cell is shunted by a resistance of 5 Ω. When the cell is shunted by a resistance of 20 Ω, the null point is obtained at 300 cm. Find the internal resistance of the cell. [**Ans.** 2·76 Ω]

36. In the circuit diagram shown in Fig. 2.76, AB is a uniform wire of resistance 10 Ω and length 1 m. It is connected series arrangement of cell E_1 of e.m.f. 2 V and negligi internal resistance and a resistor R. Terminal A is a connected to an electrochemical cell E_2 of e.m.f. 100 and a galvanometer G. In this set up, a balancing poin obtained at 40 cm mark from A. Calculate the resista of R. If E_2 were to have an e.m.f. of 300 mV, where will expect the balancing point to be ? (*C.B.S.E. 1999*
[**Ans.** 70 Ω, balance point will not be obtain

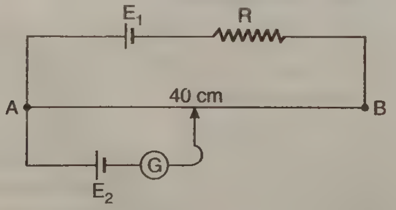

Fig. 2.76

37. Two cells of e.m.f. E_1 and E_2 ($E_1 > E_2$) are connected shown in Fig. 2.77. When a potentiometer is connec between points A and B, the balancing length of potentiomter wire is 300 cm. On connecting the sa potentiometer between points A and C, the balanci length is 100 cm. Calculate the ratio of the e.m.fs. of the t cells. (*C.B.S.E. 1994*) [**Ans.** 3

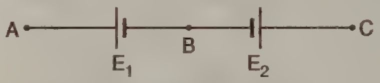

Fig. 2.77

38. A potentiometer has five segments of wire, each of len 1 m. A battery is used to pass a steady current through It is found that the e.m.f. of a cell can be balanced at cm from the zero end. Now, the battery is connected acr the four segments of wire. Find the length of potentiometer wire that will balance the e.m.f. of the c
[**Ans.** 280 c

39. A cell of e.m.f. 2·56 V and negligible internal resistanc in series with a 1 m long potentiometer wire and a resis The resistance per unit length of the wire is 0·025 ohm cm. The potential difference across a length 50·9 cm of potentiometer wire balances the e.m.f. of 1·018 V c standard cell. Find the resistance of the resistor.
[**Ans.** 0·7

40. A standard cell of e.m.f. 1·08 V is balanced by the poten difference across 91 cm of a metre long wire supplied a cell of e.m.f. 2 V through a series resistor of resista 2 Ω. The internal resistance of the 2 V cell is zero. Find resistance per unit length of the potentiometer wire.
[**Ans.** 0·0292 Ω cm

41. A potentiometer wire carries current. The potent difference across 70 cm of it balances the potent difference across a 2 ohm coil supplied by a cell of e. 2 volt. When a 1 ohm coil is placed in parallel with 2 ohm coil, a length equal to 50 cm of the potentiome wire is required to balance the potential difference acr the parallel combination. What is the internal resistance the 2 V cell ? [**Ans.** 0·5

MISCELLANEOUS PROBLEMS

42. Find the resistance between points X and Y of the netw of resistors shown in Fig. 2.78, if each resistor is resistance *r*.

[**Ans.** $\frac{8}{7}$

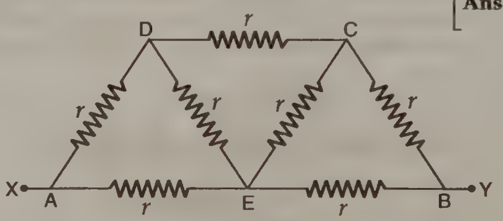

Fig. 2.78

Find the equivalent resistance of the network shown in Fig. 2.79 between the points A and B. **[Ans.** 0·8 r**]**

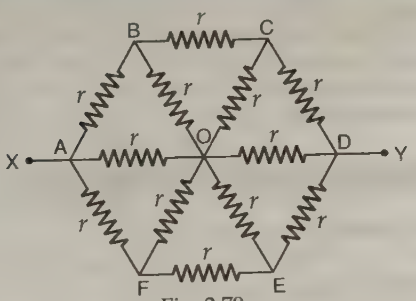

Fig. 2.79

. Find the resistance between points X and Y of the network of resistors shown in Fig. 2.80, if each resistor is of resistance r. $\left[\textbf{Ans. } \frac{10}{9} r\right]$

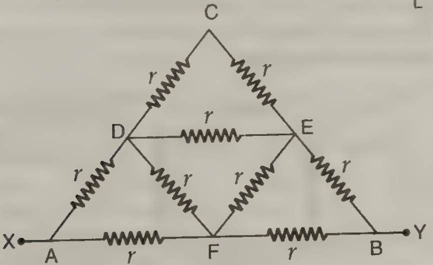

Fig. 2.80

5. Find the effective resistance between the points A and B of the network shown in Fig. 2.81. Each resistor has shown in Fig. 2.81. **[Ans.** 0·5 r**]**

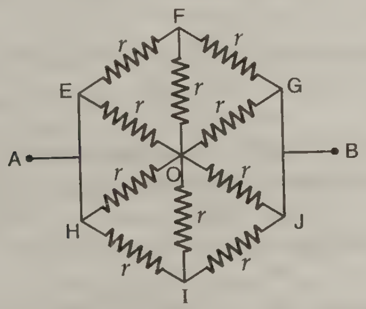

Fig. 2.81

6. Eleven resistors, each of resistance r are connected in the form of an incomplete cube as shown in Fig. 2.82. Find the resistance of the network between the points A and B of the network. $\left[\textbf{Ans. } \frac{7}{5} r\right]$

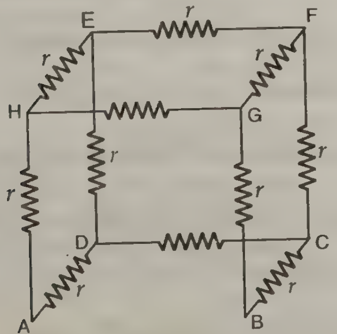

Fig. 2.82

47. ABCD is a uniform circular wire of resistance 2 Ω. AOC and BOD are two wires (each of resistance 1 Ω) forming diameters at right angles to each other. Show that the resistance of the network is 15/14 Ω, if the battery is placed in AD.

48. In the circuit shown in Fig. 2.83, calculate the potential difference across the capacitor C. **[Ans.** Zero**]**

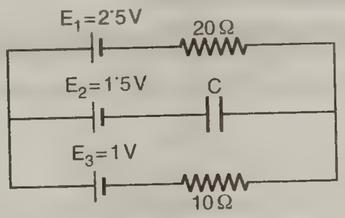

Fig. 2.83

49. In the network shown in Fig. 2.84, P = 2 Ω, Q = 2 Ω, R = 3 Ω, S = 7 Ω, C = 3 μF and E = 6 V. (*a*) Find the charge and energy stored in the capacitor. (*b*) For what value of Q, the charge on the capacitor will be zero ?

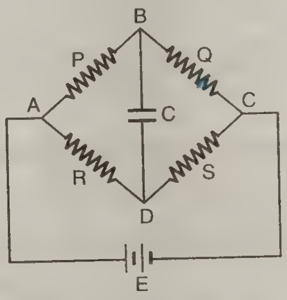

Fig. 2.84

[Ans. (*a*) 3·6 μC ; 2·16 × 10^{-6} J (*b*) = 14/3 Ω**]**

50. A certain unknown resistance is connected in the left gap and a resistance box in the right gap of a metre bridge. By introducing a resistance of 10 Ω with the help of resistance box, the balance point is determined. If the balance point shifts by 20 cm on increasing the resistance from the resistance box by 12·5 Ω, find the value of unknown resistance. **[Ans.** 15 Ω**]**

51. A short circuit occurs in a telephone cable having a resistance of 0·45 Ω m^{-1}. The circuit is tested with a Wheatstone bridge. The two resistors in the ratio arms of the Wheatstone bridge network have values of 1110 Ω and 100 Ω respectively. A balance condition is found, when the variable resistor has a value of 400 Ω. Calculate the distance down the cable, where the short has occurred. **[Ans.** 40 m**]**

52. In the circuit shown in Fig. 2.85, the uniform wire AB of the metre bridge is 1 m long and is of resistance 10 Ω. If the bridge is in balanced state, find the distance of the balance point from the end A. **[Ans.** 37·5 cm**]**

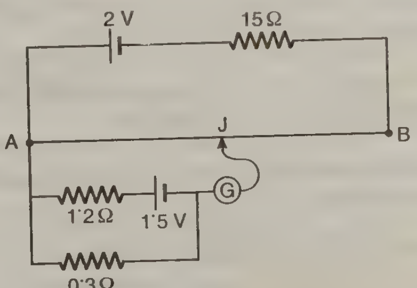

Fig. 2.85

53. A cell of e.m.f. 1·08 V is in series with a galvanometer. The series combination is placed across a resistor of resistance 108 ohm which is in series with a potentiometer wire, a battery of e.m.f. 4 V and zero internal resistance and another variable resistor. The resistance of the 1 m long potentiometer wire is 2 Ω. What should be the resistance of the variable resistor, so that the deflection in the galvanometer is to be zero? **[Ans. 290 Ω]**

54. The length of a potentiometer wire is 1200 cm and it car a current of 80 mA. For a cell of e.m.f. 4 V and inter resistance 20 Ω, the null point is found to be at 1000 cm a voltmeter is connected across the cell, the balanc length decreases by 20 cm. Find (*a*) the resistance of potentiometer wire, (*b*) reading of the voltmeter and (*c*) resistance of the voltmeter. (*C.B.S.E.* 2000 **[Ans.** (*a*) 60 Ω, (*b*) 3·92 V, (*c*) 980

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. At the junction O, according to Kirchhoff's first law, we have

$$I_1 - I_2 - I_3 = 0 \qquad ...(i)$$

Here, $V_A = 3\,E$, $V_B = 2\,E$ and $V_C = E$

Let V be potential at point O. Then,

$$V_A - V = I_1 \times r \quad \text{or} \quad 3\,E - V = I_1\, r$$

$$\text{or} \quad I_1 = \frac{3\,E - V}{r} \qquad ...(ii)$$

Again, $V - V_B = I_2 \times 2\,r$ or $V - 2\,E = 2\,I_2\, r$

$$\text{or} \quad I_2 = \frac{V - 2\,E}{2\,r} \qquad ...(iii)$$

Also, $V - V_C = I_3 \times 3\,r$ or $V - E = 3\,I_3\, r$

$$\text{or} \quad I_3 = \frac{V - E}{3\,r} \qquad ...(iv)$$

Substituting for I_1, I_2 and I_3 in equation (*i*), we have

$$\frac{3\,E - V}{r} - \frac{V - 2\,E}{2\,r} - \frac{V - 3\,E}{3\,r} = 0$$

$$\text{or} \quad 6\,(3\,E - V) - 3\,(V - 2\,E) - 2\,(V - 3\,E) = 0$$

$$\text{or} \quad 11\,V = 26\,E \quad \text{or} \quad V = \frac{26\,E}{11}$$

$$\text{Now,} \quad I_1 = \frac{3\,E - 26\,E/11}{r} = \frac{7\,E}{11\,r},$$

$$I_2 = \frac{26\,E/11 - 2\,E}{2\,r} = \frac{2\,E}{11\,r}$$

$$\text{and} \quad I_3 = \frac{26\,E/11 - E}{3\,r} = \frac{5\,E}{11\,r}$$

2. Suppose that current I flows in the circuit in the direction CBAX YC.

According to Kirchhoff's second law,

$$E_2 - E_1 = I\,(r_1 + r_2 + R)$$

$$\text{or} \quad 2{\cdot}0 - 1{\cdot}5 = I\,(1{\cdot}0 + 1{\cdot}5 + 2{\cdot}5) \quad \text{or} \quad \mathbf{I = 0{\cdot}1\ A}$$

Since current flows out from the cell E_2, potential drop across r_2 opposes its e.m.f. Therefore,

$$V_B - V_C = E_2 - I\,r_2 = 2{\cdot}0 - 0{\cdot}1 \times 1{\cdot}5 = \mathbf{1{\cdot}85\ V}$$

3. Let I be current in the circuit.

According to Kirchhoff's second law,

$$E_1 - E_2 = I\,(R_1 + R_2) \quad \text{or} \quad 12 - 8 = I\,(1{\cdot}2 + 0{\cdot}8)$$

$$\text{or} \quad I = 2\ A$$

Since current I flows out from the cell E_1, potential drop across R_1 opposes its e.m.f. Therefore,

$$V_A - V_B = E_1 - I\,R_1 = 12 - 2 \times 1{\cdot}2 = \mathbf{9{\cdot}6\ V}$$

Aliter. Since current I flows into the cell E_2, potential drop across R_2 aids its e.m.f. Therefore,

$$V_A - V_B = E_2 + I\,R_2 = 8 + 2 \times 0{\cdot}8 = \mathbf{9{\cdot}6\ V}$$

4. (*i*) By proceeding as in solved problem no. 2.02, it can be obtained that

$$I_1 = 1\ A \quad \text{and} \quad I_2 = 2{\cdot}5\ A$$

Therefore, current throgh 2 Ω resistor,

$$I = I_1 + I_2 = 1 + 2{\cdot}5 = \mathbf{3{\cdot}5\ A}$$

(*ii*) Terminal voltage across E_1,

$$V_1 = R_1 - I_1\, r_1 = 10 - 1 \times 3 = \mathbf{7\ V}$$

Terminal voltage across E_2,

$$V_2 = E_2 - I_2\, r_2 = 12 - 2{\cdot}5 \times 2 = \mathbf{7\ V}$$

5. Proceed as in problem no. 4.
6. Proceed as in problem no. 4.
7. Proceed as in solved problem no. 2.02.
8. Proceed as in solved problem no. 2.02.
9. The current through various branches of the circuit will as shown in Fig. 2.86 :

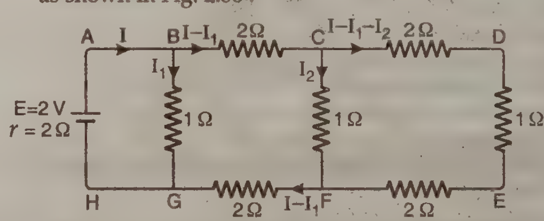

Fig. 2.86

In the closed part ABGHA of the circuit :

$$I \times 2 + I_1 \times 1 = 2$$

$$\text{or} \quad 2\,I + I_1 = 2$$

In the closed part BCFGB of the circuit :

$$(I - I_1) \times 2 + I_2 \times 1 + (I - I_1)\,2 - I_1 \times 1 = 0$$

$$\text{or} \quad 4\,I - 5\,I_1 + I_2 = 0 \qquad ...$$

In an closed part CDEFC of the circuit :

$$(I - I_1 - I_2) \times (2 + 1 + 2) - I_2 \times 1 = 0$$

$$\text{or} \quad 5\,I - 5\,I_1 - 6\,I_2 = 0 \qquad ...($$

Solving equations (*i*), (*ii*) and (*iii*), we get

$$I = \frac{70}{99}\,A\,;\ I_1 = \frac{58}{99}\,A\,;\ I_2 = \frac{10}{99}\,A$$

$$\therefore \quad I_{BC} = I_{FG} = I - I_1 = \frac{12}{99}\,A$$

$$\text{and} \quad I_{CD} = I_{DE} = I_{EF} = I - I_1 - I_2 = \frac{2}{99}\,A$$

10. Proceed as in problem no. 9.
11. Proceed as in solved problem no. 2.04.
12. (*i*) From Kirchhoff's first law, at the junction B, we ha

$$I_2 = I_1 + I_3$$

In the closed part ABEFA of the circuit :

$$6\,I_1 - 2\,I_3 = 10 \qquad ...$$

In the closed part ACDFA of the circuit :

$$4\,I_2 + 2\,I_3 = 14 \qquad ...($$

Solving equation (*i*), (*ii*) and (*iii*), we get

$$\mathbf{I_1 = 2\ A,\ I_2 = 3\ A\ \text{and}\ I_3 = 1\ A}$$

(*ii*) Potential difference between points B and E

$$= \text{potential drop across } 2\ \Omega = 2 \times I_3 = 2 \times 1 =$$

13. *In the closed part ABGHA of the circuit :*

$$3 + (-3) = I_1 \times 10 \quad \text{or} \quad I_1 = 0$$

In the closed part ACFHA of the circuit :

$$3 + 3 + (-3) + (-3) = I_2 \times 10 \quad \text{or} \quad I_2 = 0$$

In the closed part ADEHA of the circuit :

$3 + 3 + 3 + (-3) + (-3) + (-3) = I_3 \times 10$ or $I_3 = \mathbf{0}$

4. (*i*) Let the distribution of current in various branches of the circuit be as shown in Fig. 2.87 :

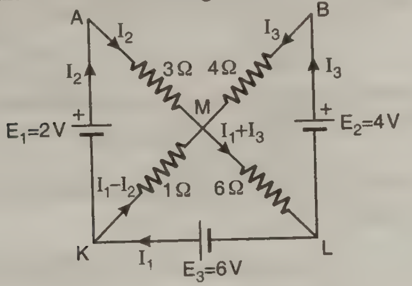

Fig. 2.87

In the closed part AKMA of the circuit :

$I_2 \times 3 - (I_1 - I_2) \times 1 = 2$

or $4\,I_2 - I_1 = 2$ ...(*i*)

In the closed part BLMB of the circuit :

$I_3 \times 4 + (I_1 + I_3) \times 6 = 4$ or $6\,I_1 + 10\,I_3 = 4$

or $3\,I_1 + 5\,I_3 = 2$ ...(*ii*)

In the closed part KLMK of the circuit :

$(I_1 - I_2) \times 1 + (I_1 + I_3) \times 6 = 6$

or $7\,I_1 - I_2 + 6\,I_3 = 6$ ...(*iii*)

Solving equations (*i*), (*ii*) and (*iii*), it can be obtained that

$$I_1 = \mathbf{1{\cdot}3\ A}$$

(*ii*) $V_A - V_B = E_1 + E_3 + (-E_2) = 2 + 6 - 4 = \mathbf{4\ V}$

15. *In the closed part E_1ABE_1 of the circuit :*

$(I_1 + I_2 - I_3) \times R_1 - (I_3 - I_1) \times R_2 = E_1$

or $(I_1 + I_2 + I_3) \times 2 - (I_3 - I_1) \times 2 = 5$

or $4\,I_1 + 2\,I_2 - 4\,I_3 = 5$ ...(*i*)

In the closed part E_1ACBE_1 of the circuit :

$-(I_2 - I_3) \times R_4 + I_3 \times R_5 = E_1$

or $-(I_2 - I_3) \times 4 + I_3 \times 4 = 5$

or $-4\,I_2 + 8\,I_3 = 5$ ...(*ii*)

In the closed part BCOB of the circuit :

$I_2 \times R_3 + I_3 \times R_5 + (I_3 - I_1) \times R_2 = E_2$

or $I_2 \times 1 + I_3 \times 4 + (I_3 - I_1) \times 2 = 10$

or $-2\,I_1 + I_2 + 6\,I_3 = 10$ ...(*iii*)

Solving equations (*i*), (*ii*) and (*iii*), it can be obtained that

$I_1 = I_3 = \mathbf{1{\cdot}875\ A}$ and $I_2 = \mathbf{2{\cdot}5\ A}$

16. Since the bridge is balanced $\left(\frac{2}{3} = \frac{4}{6}\right)$, no current flows along the path CD. Thus, 10 Ω resistance is ineffective and may be ignored.

Resistance of branch XCY, $R_1 = 2 + 3 = 5\ \Omega$

and resistance of branch XDY, $R_2 = 4 + 6 = 10\ \Omega$

Therefore, effective resistance between points X and Y,

$$R = \frac{R_1 \times R_2}{R_1 + R_2} = \frac{5 \times 10}{5 + 10} = \frac{50}{15} = \mathbf{3{\cdot}33\ \Omega}$$

17. The given circuit is an arrangement of balanced Wheatstone bridge and therefore AB may be treated as an open path.

Resistance of branch XAY, $R_1 = 10 + 10 = 20\ \Omega$

Resistance of branch XBY, $R_2 = 10 + 10 = 20\ \Omega$

Therefore, effective resistance between points X and Y is given by

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{40} = \frac{1}{20} + \frac{1}{20} + \frac{1}{40} = \frac{5}{40}$$

or $R = \mathbf{8\ \Omega}$

18. The given circuit may be arranged shown in Fig. 2.88 :

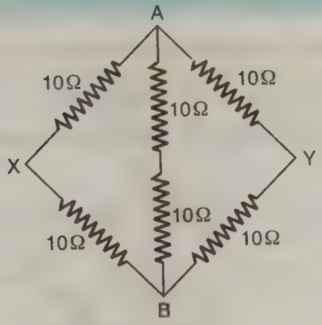

Fig. 2.88

Now, proceed as in problem no. 16.

19. The given network can be arranged as shown in Fig. 2.89 :

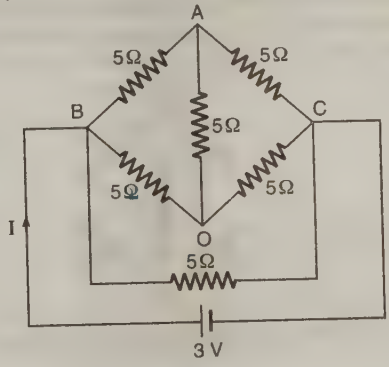

Fig. 2.89

It is a balanced Wheatstone bridge. Proceeding as in problem no. 17, it can be obtained that the effective resistance of the network,

$$R = 2{\cdot}5\ \Omega$$

Therefore, current drawn by the circuit,

$$I = \frac{3}{2{\cdot}5} = \mathbf{1{\cdot}2\ A}$$

20. The given network can be rearranged as shown in Fig. 2.90 :

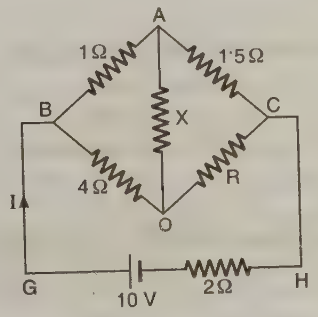

Fig. 2.90

As the current through branch AO is zero, the bridge is balanced *i.e.*

$$\frac{1}{1{\cdot}5} = \frac{4}{R} \quad \text{or} \quad R = 4 \times 1{\cdot}5 = 6\ \Omega$$

Resistance of branch BAC, $R_1 = 1 + 1{\cdot}5 = 2{\cdot}5\ \Omega$

Resistance of branch BOC, $R_2 = 4 + 6 = 10\ \Omega$

Hence, equivalent resistance of the circuit,

$$R_{equi} = \frac{R_1 R_2}{R_1 + R_2} + 2 = \frac{2{\cdot}5 \times 10}{2{\cdot}5 + 10} + 2 = 2 + 2 = 4\,\Omega$$

Now, current in the main circuit, $I = \frac{10}{R_{equi}} = \frac{10}{4} = 2\cdot5\ \text{A}$

Hence, current through R (or branch BOC),

$$I' = \frac{I \times R_1}{R_1 + R_2} = \frac{2\cdot5 \times 2\cdot5}{2\cdot5 + 10} = \mathbf{0\cdot5\ A}$$

21. The given network can be rearranged as shown in Fig. 2.91 :

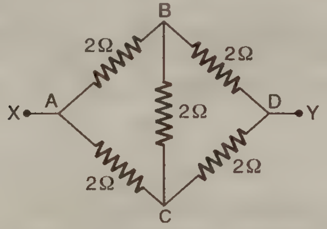

Fig. 2.91

It is a balanced Wheatstrone bridge. Its effective resistance can be found by proceeding as in problem no. 16.

22. The given network can be rearranged as shown in Fig. 2.92 :

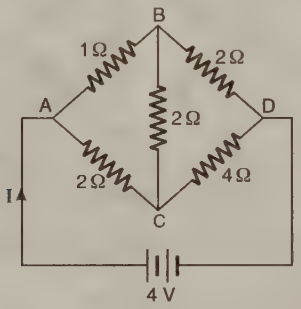

Fig. 2.92

It is a balanced Wheatstone bridge.

The effective resistance of network,

$$R = \frac{3 \times 6}{3+6} = 2\,\Omega$$

Therefore, current drawn by the circuit, $I = 4/2 = \mathbf{2\ A}$

23. Proceed as in solved problem no. 2.09.

24. At the junction A, according to Kirchhoff's first law, we have

$$I = I_1 + I_2 \qquad \text{...}(i)$$

In closed part ABDA of the circuit :

$$I_1 \times 2 + I_3 \times 4 - I_2 \times 1 = 0$$

or $$2\,I_1 - I_2 + 4\,I_3 = 0 \qquad \text{...}(ii)$$

In closed part BCDB of the circuit :

$$(I_1 - I_3) \times 3 - (I_2 + I_3) \times 2 - I_3 \times 4 = 0$$

or $$3\,I_1 - 2\,I_2 - 9\,I_3 = 0 \qquad \text{...}(iii)$$

In closed part ABCHGA of the circuit :

$$I_1 \times 2 + (I_1 - I_3) \times 3 + I \times 2 = 2$$

or $$I_1 \times 2 + (I_1 - I_3) \times 3 + (I_1 + I_2) \times 2 = 2$$

or $$7\,I_1 + 2\,I_2 - 3\,I_3 = 2 \qquad \text{...}(iv)$$

Solving equations (*ii*), (*iii*) and (*iv*), it can be obtained that

$$I_1 = \frac{\mathbf{17}}{\mathbf{91}}\ \text{A};\ I_2 = \frac{\mathbf{30}}{\mathbf{91}}\ \text{A} \quad \text{and} \quad I_3 = -\frac{\mathbf{1}}{\mathbf{91}}\ \text{A}$$

From equation (*i*), we have

$$I = I_1 + I_2 = \frac{17}{91} + \frac{30}{91} = \frac{\mathbf{47}}{\mathbf{91}}\ \text{A}$$

25. Proceed as in problem no. 24.

26. Resistance in left arm, $R_p = \frac{5 \times 20}{5+20} = 4\,\Omega$

Let X be resistance in the right arm. Then,

$$\frac{4}{X} = \frac{40}{(100-40)} \quad \text{or} \quad X = \frac{4 \times 60}{40} = \mathbf{6\ \Omega}$$

27. Proceed as in solved problem no. 2.12.

28. Let X be unknown resistance. Then,

$$\frac{2}{X} = \frac{40}{(100-40)} \quad \text{or} \quad X = \frac{2 \times 60}{40} = 3\,\Omega$$

When unknown resistance is shunted with 2 Ω resistor :

$$X' = \frac{X \times 2}{X+2} = \frac{3 \times 2}{3+2} = 1\cdot2\ \Omega$$

If balanced point is obtained at a distance l' from the left end, then,

$$\frac{2}{X'} = \frac{l'}{(100-l')} \quad \text{or} \quad \frac{2}{1\cdot2} = \frac{l'}{(100-l')}$$

$$l' = 62\cdot5\ \text{cm}$$

Therefore, shift in balance point,

$$l' - l = 62\cdot5 - 40 = \mathbf{22\cdot5\ cm}$$

29. Resistance in right gap, $X = 2\ \Omega$

Let S be the resistance of shunt wire. Then,

resistance in left gap, $R = \frac{5 \times S}{5+S} = \frac{5S}{5+S}$

Now, $\frac{R}{X} = \frac{l}{100-l}$ or $\frac{5S}{(5+S)\times 2} = \frac{62\cdot5}{100-62\cdot5}$

or $\quad S = \mathbf{10\ \Omega}$

30. Resistance in right gap, $X = R$

When resistance R_1 is in left gap :

$$\frac{R_1}{R} = \frac{40}{(100-40)} \quad \text{or} \quad R_1 = \frac{2R}{3}$$

When resistance R_2 is in left gap :

$$\frac{R_2}{R} = \frac{50}{100-50} \quad \text{or} \quad R_2 = R$$

(*a*) $R_s = R_1 + R_2 = \frac{2R}{3} + R = \frac{5R}{3}$

Now, $\frac{R_s}{R} = \frac{l}{100-l}$ or $\frac{5R/3}{R} = \frac{l}{100-l}$

or $\quad l = \mathbf{62\cdot5\ cm}$

(*b*) $R_p = \frac{R_1\,R_2}{R_1+R_2} = \frac{(2R/3)\times R}{(2R/3)+R} = 0\cdot4\,R$

Now, $\frac{R_p}{R} = \frac{l}{100-l}$ or $\frac{0\cdot4\,R}{R} = \frac{l}{100-l}$

or $\quad l = \mathbf{28\cdot6\ \ cm}$

31. Let l be total length of the wire of metre bridge.

Now, $$\frac{P}{Q} = \frac{30}{l-30} \qquad \text{...}(i)$$

When coils P and Q are interchanged :

$$\frac{Q}{P} = \frac{120}{l-120} \qquad \text{...}(ii)$$

Multiplying equations (*i*) and (*ii*), we have

$$\frac{P}{Q} \times \frac{Q}{P} = \frac{30}{l-30} \times \frac{120}{l-120} \quad \text{or} \quad (l-30)\,(l-120) = 3600$$

or $\quad l^2 - 150\,l + 3600 = 3600 \quad$ or $\quad l = \mathbf{150\ cm}$

Substituting for l in equation (*i*), we have

$$\frac{P}{Q} = \frac{30}{150-30} = \frac{\mathbf{1}}{\mathbf{4}}$$

32. $r = \left(\frac{E}{V} - 1\right)S = \left(\frac{l_1}{l_2} - 1\right)S = \left(\frac{85}{75} - 1\right) \times 7\cdot5 = \mathbf{1\ \Omega}$

33. Proceed as in problem no. 32.

34. Proceed as in problem no. 32.

35. ***When shunted by 5 Ω resistor :***

$$r=\left(\frac{l_1}{220}-1\right)\times 5 \qquad ...(i)$$

When shunted by 20 Ω resistor :

$$r=\left(\frac{l_1}{300}-1\right)\times 20 \qquad ...(ii)$$

$$\therefore\ \left(\frac{l_1}{220}-1\right)\times 5=\left(\frac{l_1}{300}-1\right)\times 20 \quad \text{or} \quad l_1 = 341{\cdot}4 \text{ cm}$$

Substituting for l_1 in equation (*i*), we have

$$r=\left(\frac{341\cdot 4}{220}-1\right)\times 5=\mathbf{2{\cdot}76\ \Omega}$$

36. Current through potentiometer wire,

$$I=\frac{E_1}{R+R_{AB}}=\frac{2}{R+10}$$

Resistance of balancing length of the wire,

$$R'=\frac{10}{100}\times 40=4\,\Omega$$

$\therefore$ E_2 = potential drop across R′

$$\text{or } 100\times 10^{-3}=4\times\frac{2}{R+10}$$

$$\text{or} \qquad R=\frac{8}{100\times 10^{-3}}-10=\mathbf{70\ \Omega}$$

Potential drop across whole length of potentiometer wire,

$$V=R_{AB}\times I=10\times\frac{2}{10+10}=0\cdot 1\text{ V}=100\text{ mV}$$

Since V is less than 300 mV, balance point **will not be obtained,** if E_2 were to have an e.m.f. of 300 mV.

37. ***When potentiometer is connected between the points A and B :***

$$E_1 \propto 300 \qquad ...(i)$$

When potentiometer is connected between points A and C :

The net e.m.f. of the two cells = $E_1 - E_2$

$$\therefore \qquad E_1 - E_2 \propto 100 \qquad ...(ii)$$

Dividing equation (*ii*) by (*i*), we have

$$\frac{E_1-E_2}{E_1}=\frac{100}{300} \quad \text{or} \quad 1-\frac{E_2}{E_1}=\frac{1}{3}$$

$$\text{or} \qquad \frac{E_1}{E_2}=\frac{3}{2}$$

38. Let *r* be resistance of 1 cm length of the potentiometer wire. Then, total resistance of potentiometer wire = 500 *r*

In first case : If E′ is e.m.f. of the battery used to pass current through the potentiometer wire, then

$$I_1=\frac{E'}{500\,r}$$

If E is e.m.f. of the cell, then

E = potential drop across 350 cm long wire

$$=350\,r\times I_1=\frac{350\,r\times E'}{500\,r}$$

$$\text{or} \qquad E'=\frac{10\,E}{7}$$

In second case : Current through potentiometer wire,

$$I_2=\frac{E'}{400\,r}=\frac{10\,E}{7\times 400\,r}=\frac{E}{280\,r}$$

Suppose that the e.m.f. of the cell is balanced against length *l* of the potentiometer wire.

Then, E = potential drop across length *l* of the wire

$$\text{or} \qquad E=\frac{E}{280\,r}\times l\,r \qquad \text{or} \qquad l=\mathbf{280\ cm}$$

39. Let R be resistance of the resistor.

Resistance of the potentiometer wire

$$=100\times 0{\cdot}025=2{\cdot}5\ \Omega$$

Therefore, current through the potentiometer wire,

$$I=\frac{2\cdot 56}{R+2\cdot 5}$$

Now, 1·018 = potential drop across 50·9 cm of potentiometer wire

$$=50\cdot 9\times 0\cdot 025\times\frac{2\cdot 56}{R+2\cdot 5}$$

$$\text{or} \qquad R=\frac{50\cdot 9\times 0\cdot 025\times 2\cdot 56}{1\cdot 018}-2\cdot 5=3\cdot 2-2\cdot 5$$

$$=\mathbf{0{\cdot}7\ \Omega}$$

40. Proceed as in problem no. 39.

41. Let *r* be internal resistance of the cell.

In first case : Current sent by the cell through 2 Ω coil,

$$I_1=\frac{\text{e.m.f.}}{\text{total resistance}}=\frac{2}{2+r}$$

Potential drop acorss 2 Ω coil,

$$V_1=2\times I_1=2\times\frac{2}{2+r}=\frac{4}{2+r}$$

$$\text{Now,} \qquad V_1 \propto 70\text{ cm}$$

$$\text{or} \qquad \frac{4}{2+r}\propto 70 \qquad ...(i)$$

In second case : Let R_p be resistance of the parallel combination of 2 Ω and 1 Ω coils. Then,

$$R_p=\frac{2\times 1}{2+1}=\frac{2}{3}\ \Omega$$

Current sent by the cell through R_p,

$$I_2=\frac{\text{e.m.f.}}{\text{total resistance}}=\frac{2}{2/3+r}$$

Potential drop across R_p,

$$V_2=R_p\times I_2=\frac{2}{3}\times\frac{2}{2/3+r}=\frac{4}{2+3r}$$

$$\text{Now,} \qquad V_2 \propto 50\text{ cm}$$

$$\text{or} \qquad \frac{4}{2+3r}\propto 50 \qquad ...(ii)$$

Dividing equation (*i*) by (*ii*), we have

$$\frac{4}{2+r}\times\frac{2+3r}{4}=\frac{70}{50} \qquad \text{or} \qquad r=\mathbf{0{\cdot}5\ \Omega}$$

42. Consider that a cell is connected across the points X and Y, so that current I enters at point A and leaves at point B. Due to symmetry, the distribution of current in various branches will be as shown in Fig. 2.93 :

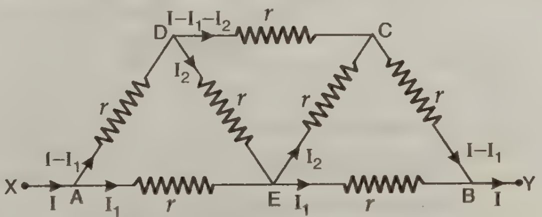

Fig. 2.93

Since current in branch DE is same as that in branch EC, it will remain so even when contract between branch DEC and AEB is broken at point E as shown in Fig. 2.94 :

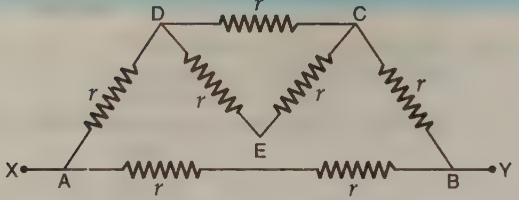

Fig. 2.94

Therefore, resistance of the given network is same as that of the circuit as shown above.

Now, resistance of branch AB, $R_1 = r + r = 2r$

and resistance of branch ADCB,

$$R_2 = r + \frac{r \times 2r}{r + 2r} + r = \frac{8r}{3}$$

Since R_1 and R_2 are in parallel, resistance of the network between points X and Y,

$$R = \frac{R_1 R_2}{R_1 + R_2} = \frac{2r \times 8r/3}{2r + 8r/3} = \frac{8r}{7}$$

Aliter. *For closed part ADEA of the circuit :*

$$(I - I_1)\, r + I_2\, r - I_1\, r = 0$$

or $$I - 2I_1 + I_2 = 0 \qquad ...(i)$$

For closed part CDEC of the circuit :

$$I_2\, r + I_2\, r - (I - I_1 - I_2)\, r = 0$$

or $$I - I_1 - 3I_2 = 0 \qquad ...(ii)$$

From equations (*i*) and (*ii*), by eliminating I_2, we have

$$I_1 = \frac{4}{7} I \qquad ...(iii)$$

If R is resistance of the network, then

$$V_A - V_B = I R \qquad ...(iv)$$

Also, $V_A - V_B = I_1 r + I_1 r$

or $$V_A - V_B = 2 I_1 r \qquad ...(v)$$

From equations (*iv*) and (*v*), we have

$$I R = 2 I_1 r = 2 \times \frac{4}{7} I \times r \qquad \left(\because I_1 = \frac{4}{7} I\right)$$

or $$R = \frac{8}{7} r$$

43. By proceeding as in problem no. 42, it can be shown that the given network is equivalent to the circuit shown in Fig. 2.95 :

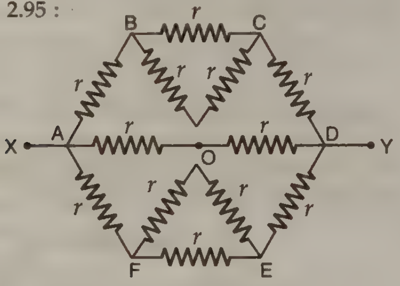

Fig. 2.95

As obtained earlier,

resistance of branch ABCD, $R_1 = \frac{8r}{3}$

resistance of branch AD, $R_2 = 2r$

and resistance of branch AFED, $R_3 = \frac{8r}{3}$

Since R_1, R_2 and R_3 are in parallel, resistance of the network between points X and Y is given by

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} = \frac{3}{8r} + \frac{1}{2r} + \frac{3}{8r} = \frac{10}{8r}$$

or $$R = 0{\cdot}8\, r$$

Note. The problem can also be solved by applying Kirchh laws as in problem no. 42.

44. As discussed in problem no. 42, the resistance of g network will remain the same, if the contact betweer branches AB and ADCEB is broken at point F.

Resistance of the branch AB, $R_1 = r + r = 2r$

Resistance of the part CDFE of the branch ADCEB (w contact is broken at point F) is given by

$$\frac{1}{R_p} = \frac{1}{2r} + \frac{1}{r} + \frac{1}{2r} \qquad \text{or} \qquad R = \frac{r}{2}$$

Therefore, resistance of the branch ADCEB,

$$R_2 = r + R_p + r = r + \frac{r}{2} + r = \frac{5r}{2}$$

Hence, resistance of the given network between the p X and Y,

$$R = \frac{R_1 R_2}{R_1 + R_2} = \frac{2r \times 5r/2}{2r + 5r/2} = \frac{10r}{9}$$

44. Since $\frac{R_{EF}}{R_{FG}} = \frac{R_{EO}}{R_{OG}}$,

no current will flow along path FO and hence FO ac an open path. For the same reason, OI also acts as an path. As such, the given network can be rearrange shown in Fig. 2.96 :

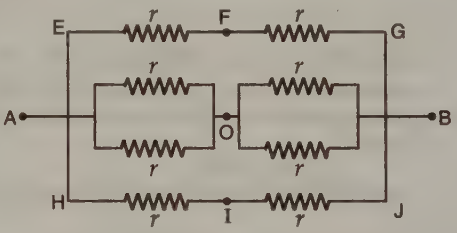

Fig. 2.96

Now, resistance of the branch EFG, $R_1 = r + r = 2r$,

resistance of the branch HIJ, $R_2 = r + r = 2r$

and resistance of the branch AOB, $R_3 = r/2 + r/2 =$

The resistances R_1, R_2 and R_3 of these branches a parallel. Therefore, effective resistance of the netwo

$$\frac{1}{R} = \frac{1}{2r} + \frac{1}{2r} + \frac{1}{r} = \frac{2}{r} \qquad \text{or} \qquad R = 0{\cdot}5\ \Omega$$

46. Suppose that a battery of e.m.f. E is connected a the points A and B of the incomplete cube as show Fig. 2.97 :

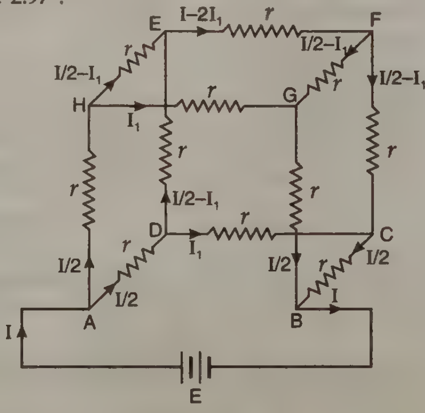

Fig. 2.97

Further, suppose that a current I enters the cube at point A. As the paths ADCB and AHGB are of equal resistances, current $\frac{I}{2}$ will flow along each of the two paths. Suppose that at point D, a part I_1 flows along the path DC. Then, the remaining part $\frac{I}{2} - I_1$ will along the path DE. In a similar manner, current equal to I_1 will flow along the path HG and $\frac{I}{2} - I_1$ along the path HE. The distribution of current in the other branches of the circuit will be as shown in the figure. If R is the resistance of the cube between the points A and B, then

$$R = \frac{E}{I} \qquad \ldots(i)$$

In the closed part ADCBA of the circuit :

$$E = \frac{I}{2} \times r + I_1 \times r + \frac{I}{2} \times r$$

or $$E = I\,r + I_1\,r \qquad \ldots(ii)$$

In the closed part EFGHE of the circuit :

$$(I - 2I_1) \times r + \left(\frac{I}{2} - I_1\right) r - I_1 \times r + \left(\frac{I}{2} - I_1\right) r = 0$$

or $$(I - 2I_1) + \left(\frac{I}{2} - I_1\right) - I_1 + \left(\frac{I}{2} - I_1\right) = 0$$

or $$I_1 = \frac{2}{5} I$$

Substituting for I_1 in equation (*ii*), we have

$$E = I\,r + \frac{2}{5} I\,r = \frac{7}{5} I\,r$$

or $$\frac{E}{I} = \frac{7}{5} r \qquad \ldots(iii)$$

From equations (*i*) and (*iii*), we have

$$R = \frac{7}{5} r$$

47. Suppose that a battery of e.m.f. E is connected in AD. Let the distribution of currents in various branches of the circuit be as shown in Fig. 2.98 :

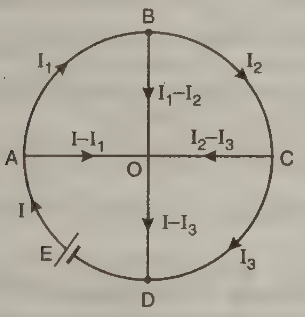

Fig. 2.98

It follows that $R_{AB} = R_{BC} = R_{CD} = R_{DA} = \frac{2}{4} = 0{\cdot}5\ \Omega$

Also, $R_{AO} = R_{OC} = R_{BO} = R_{OD} = \frac{1}{2} = 0{\cdot}5\ \Omega$

If R is resistance of the network, then

$$R = \frac{E}{I} \qquad \ldots(i)$$

In the closed part AODA of the circuit :

$$I \times 0{\cdot}5 + (I - I_1) \times 0{\cdot}5 + (I - I_3) \times 0{\cdot}5 = E$$

or $$1{\cdot}5\,I - 0{\cdot}5\,I_1 - 0{\cdot}5\,I_3 = E \qquad \ldots(ii)$$

In the closed part ABOA of the circuit :

$$I_1 \times 0{\cdot}5 + (I_1 - I_2) \times 0{\cdot}5 - (I - I_1) \times 0{\cdot}5 = 0$$

or $$3\,I_1 - I_2 = I \qquad \ldots(iii)$$

In the closed part BCOB of the circuit :

$$I_2 \times 0{\cdot}5 + (I_2 - I_3) \times 0{\cdot}5 - (I_1 - I_2) \times 0{\cdot}5 = 0$$

or $$I_1 - 3\,I_2 + I_3 = 0 \qquad \ldots(iv)$$

In the closed part CODC of the circuit :

$$I_3 \times 0{\cdot}5 - (I_2 - I_3) \times 0{\cdot}5 - (I - I_3) \times 0{\cdot}5 = 0$$

or $$I_2 = 3\,I_3 - I \qquad \ldots(v)$$

Substituting for I_2 in equation (*iii*), we have

$$3\,I_1 - (3\,I_3 - I) = I \quad \text{or} \quad I_3 = I_1$$

Substituting for I_3 in equation (*v*), we have

$$I_2 = 3\,I_1 - I$$

Setting $I_2 = 3\,I_1 - I$ and $I_3 = I_1$ in equation (*iv*), we have

$$I_1 - 3\,(3\,I_1 - I) + I_1 = 0 \quad \text{or} \quad 7\,I_1 = 3\,I$$

or $$I_1 = \frac{3}{7} I$$

Setting $I_1 = I_3 = \frac{3}{7} I$ in equation (*ii*), we have

$$1{\cdot}5\,I - 0{\cdot}5 \times \frac{3}{7} I - 0{\cdot}5 \times \frac{3}{7} I = E$$

or $$\frac{E}{I} = 1{\cdot}5\left(1 - \frac{1}{7} - \frac{1}{7}\right)$$

or $$\frac{E}{I} = \frac{15}{14} \qquad \ldots(vi)$$

From equations (*i*) and (*vi*), we have

$$R = \frac{15}{14}\ \Omega$$

48. In the steady state, current can not flow through the capacitor and hence the branch of the circuit containing capacitor can be considered as an open path. Likewise, the given network is equivalent to the circuit as shown in Fig. 2.99 :

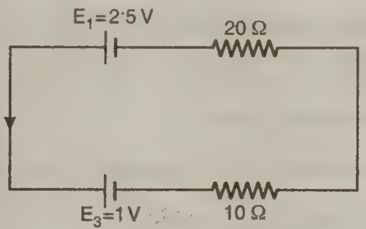

Fig. 2.99

Let I be current in the circuit.

According to Kirchhoff's second law,

$$20 \times I + 10\,I = E_1 - E_3 \quad \text{or} \quad 30\,I = 2{\cdot}5 - 1$$

or $$I = 0{\cdot}05 \text{ A}$$

Potential difference across C

= terminal potential difference across E_1 (or E_3) − E_2

Now, terminal potential difference across E_1

$$= E_1 - I \times 20$$
$$= 2{\cdot}5 - 0{\cdot}05 \times 20 = 1{\cdot}5 \text{ V}$$

Therefore, potential difference across C = 1·5 − 1·5 = 0

49. In steady state, the capacitor behaves as an open path.

Now, $V_A = 6$ V and $V_C = 0$

Since battery is connected across series combination of P and Q,

$$\frac{V_A - V_B}{V_B - V_C} = \frac{P}{Q} = \frac{2}{2} = 1$$

or $$V_A - V_B = V_B - V_C$$

or $$6 - V_B = V_B - 0 \quad \text{or} \quad V_B = 3 \text{ V}$$

Since battery is connected across series combination of R and S,

$$\frac{V_A - V_D}{V_D - V_C} = \frac{R}{S} = \frac{3}{7}$$

or $7(V_A - V_D) = 3\,(V_D - V_C)$

or $7\,(6 - V_D) = 3\,(V_D - 0)$ or $V_D = 4{\cdot}2$ V

$\therefore$ $V_D - V_B = 4{\cdot}2 - 3 = 1{\cdot}2$ V

(*a*) Charge stored in the capacitor,

$$q = C\,(V_D - V_B) = 3 \times 1{\cdot}2 = \mathbf{3{\cdot}6\ \mu C}$$

Energy stored in the capacitor,

$$U = \frac{1}{2} C\,(V_D - V_B)^2 = \frac{1}{2} \times 3 \times 10^{-6} \times (1{\cdot}2)^2$$

$$= \mathbf{2{\cdot}16 \times 10^{-6}\ J}$$

(*b*) When $V_B = V_D$ *i.e.* when bridge is balanced, no charge will be stored in the capacitor. The value of Q for balanced bridge is given by

$$\frac{2}{Q} = \frac{3}{7} \quad \text{or} \quad Q = \frac{14}{3}\,\Omega$$

50. Suppose that the balance point is obtained at a distance l from the zero mark. Then,

$$\frac{X}{R} = \frac{l}{100 - l} \quad \text{or} \quad \frac{X}{10} = \frac{l}{100 - l}$$

or $$X = \frac{10\,l}{100 - l} \qquad ...(i)$$

On increasing resistance by 12·5 Ω :

Since R has been increased, balancing length will decrease. Suppose that it becomes equal to l'.

Here, $R' = 10 + 12{\cdot}5 = 22{\cdot}5\ \Omega$ and $l' = l - 20$

Now, $$\frac{X}{R'} = \frac{l'}{100 - l'} \quad \text{or} \quad \frac{X}{22{\cdot}5} = \frac{l - 20}{100 - (l - 20)}$$

or $$X = \frac{22{\cdot}5\,(l - 20)}{120 - l} \qquad ...(ii)$$

From equations (*i*) and (*ii*), we have

$$\frac{10\,l}{100 - l} = \frac{22{\cdot}5\,(l - 20)}{(120 - l)} \quad \text{or} \quad \frac{l}{100 - l} = \frac{2{\cdot}25\,(l - 20)}{120 - l}$$

On solving, we get

$l = 60$ cm

Substituting for l in equation (*i*), we have

$$X = \frac{10 \times 60}{100 - 60} = \mathbf{15\ \Omega}$$

51. Suppose that the short circuit occurs in the telephone cable at a distance d. Then,

length of cable, $l = 2\,d$

resistance of telephone cable, $X = 2\,d \times 0{\cdot}45\ \Omega$

Now, $$X = R\frac{Q}{P}$$

Here, $P = 1110\ \Omega$, $Q = 100\ \Omega$ and $R = 400\ \Omega$

$$\therefore \quad 2\,d \times 0{\cdot}45 = \frac{400 \times 100}{1110}$$

or $d = \mathbf{40\ m}$

52. Current through the potentiometer wire,

$$I = \frac{2}{15 + R_{AB}} = \frac{2}{15 + 10} = 0{\cdot}08\ A$$

Potential drop across wire AB = 0·08 × 10 = 0·8 V

Potential drop per unit length of wire AB

$$= \frac{0{\cdot}8}{1} = 0{\cdot}8\ V\ m^{-1}$$

Let AJ be equal to l.

Then, potential drop across portion AJ of the wire,

$V = l \times 0{\cdot}8$

Let I′ be the current sent by 1·5 V cell through the series combination of 1·2 Ω and 0·3 Ω resistors. Then,

$$I' = \frac{1{\cdot}5}{1{\cdot}2 + 0{\cdot}3} = 1\ A$$

In the balanced state,

V = potential drop across 0·3 Ω resistor

$= I' \times 0{\cdot}3 = 1 \times 0{\cdot}3$

or $V = 0{\cdot}3$ ...(*ii*)

From equations (*i*) and (*ii*), we have

$l \times 0{\cdot}8 = 0{\cdot}3$

or $$l = \frac{0{\cdot}3}{0{\cdot}8} = 0{\cdot}375\ m = \mathbf{37{\cdot}5\ cm}$$

53. The various components are connected as shown in Fig. 2.100 :

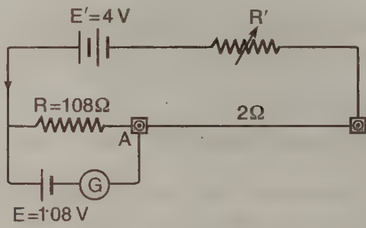

Fig. 2.100

Let R′ be the resistance of the variable resistor, which makes deflection on the galvanometer equal to zero.

Total resistance of the circuit = $R' + R + R_{AB}$

$= R' + 108 + 2 + R' + 110$

Therefore, current through the circuit,

$$I = \frac{E'}{R' + 110} = \frac{4}{R' + 110}$$

and potential difference across resistor R,

$$V = I\,R = \frac{4 \times 108}{R' + 110}$$

Since galvanometer does not show deflection,

$$V = E \quad \text{or} \quad \frac{4 \times 108}{R' + 110} = 1{\cdot}08$$

or $$R' = \frac{4 \times 108}{1{\cdot}08} - 110 = 400 - 110 = \mathbf{290\ \Omega}$$

54. (*a*) Current through the potentiometer wire,

$I = 80\ mA = 80 \times 10^{-3}$ A

The e.m.f. 4 V of the cell is balanced against 1000 cm of the potentiometer wire. Therefore,

$$\text{resistance of 1000 cm of wire, } R' = \frac{4}{80 \times 10^{-3}} = 50\ \Omega$$

Hence, resistance of the whole length of potentiometer wire,

$$R = \frac{R'}{1000} \times 1200 = \frac{50}{1000} \times 1200 = \mathbf{60\ \Omega}$$

(*b*) When voltmeter is connected across the cell, it will draw some current. The terminal potential difference across the two poles of the cell is balanced against 980 cm length of the potentiometer wire. Therefore,

$$\text{reading of voltmeter} = \frac{4}{1000} \times 980 = \mathbf{3{\cdot}92\ V}$$

(*c*) Let R_V be resistance of the voltmeter. Then,

$$r = \left(\frac{E}{V} - 1\right) R_V = \left(\frac{l_1}{l_2} - 1\right) R_V$$

or $$20 = \left(\frac{1000}{980} - 1\right) R_V \quad \text{or} \quad R_V = \mathbf{980\ \Omega}$$

CHAPTER

3

Thermal Effects of Current

3.01. THERMAL EFFECT OF CURRENTS

In 1841, Joule experimentally showed the heating effect of the electric current. When electric current is passed through the element of a heater or an electric bulb, it becomes hot due to conversion of electrical energy into heat energy.

When potential difference is applied across the two ends of a conductor, an electric field is set up across its ends. Under the effect of the electric field, the electrons get accelerated and move in a direction opposite to the direction of the electric field. As they move, they collide against the ions or atoms in the conductor and in this process, the electrons transfer their kinetic energy to the atoms. As a result, the average kinetic energy of the atoms increases and consequently the temperature of the conductor rises. It is termed as heating effect of the electric currents.

Key point

On passing current, heat is produced in a conductor due to transfer of energy from electrons (constituting the current) to the ions and atoms in the conductor.

3.02. ELECTRIC POWER

The rate at which work is done by the source of e.m.f. in maintaining the electric current in a circuit is called electric power of the circuit.

If an amount of work W is done in maintaining electric current for a time t in the circuit, then electric power of the circuit,

$$P = \frac{W}{t} \qquad ...(3.01)$$

Consider a resistor of resistance R, across which a potential difference V is applied [Fig. 3.01]. According to Ohm's law, the current I flowing through the resistor is given by

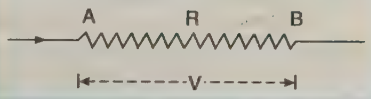

Fig. 3.01

$$V = I R$$

Suppose that the steady current I flows through the resistor for a time t. Then, total charge that crosses through the resistor is given by

$$q = I t$$

If current* flows from end A to B, then potential of end A must be higher than that of B. Since potential difference across the conductor is V, the potential of end A is higher than that of B by an amount V. From the definition of potential difference, it follows that if a unit charge is made to cross the resistor from the end B to A (from the end at lower potential to that at higher potential), work equal to V has to be done. Conversely, if a unit charge flows from end A to B, then energy equal to V will be consumed from the source of e.m.f. and it will appear as heat energy across the resistor. If current I flows for time t *i.e.* charge equal to I t crosses the resistor from the end A to B, then electrical energy dissipated is given by

$$W = V I t \qquad ...(3.02)$$

If V is in **volt**, I in **ampere** and t in **seconds**, then energy dissipated will be in **joule**.

From equations (3.01) and (3.02), we have

$$P = V I \qquad ...(3.03)$$

The SI unit of electric power is **watt**.

1 watt = 1 volt × 1 ampere or 1 W = 1 V × 1 A

The electric power of a circuit or a device is said to be one watt, if one ampere of current flows through it, when a constant potential difference of one volt is applied across it.

The bigger units of electric power are **kilowatt (kW)** and **megawatt (MW)**.

$$\mathbf{1\ kW = 10^3\ W \text{ and } 1\ MW = 10^6\ W}$$

The power of electric circuit in kilowatt is given by

$$P\,(\text{in kW}) = \frac{V\,(\text{in volt}) \times I\,(\text{in ampere})}{1000}$$

---

*Conventional current *i.e.* the current which flows from positive to negative pole of a battery.

Expression for electric power in terms of I and R. Since V = I R, equation (3.03) becomes

$$P = I^2 R \qquad \text{...(3.04)}$$

Expression for electric power in terms of V and R. Since $I = \frac{V}{R}$, equation (3.03) becomes

$$P = \frac{V^2}{R} \qquad \text{...(3.05)}$$

3.03. ELECTRIC ENERGY

The total work done (or energy supplied) by the source of e.m.f. in maintaining the electric current in the circuit for a given time is called electric energy consumed in the circuit.

The equation (3.02) gives electric energy consumed in the circuit in time t. Since V I = P (electric power of the circuit), equation (3.02) may be rewritten as

$$W = P\,t \qquad \text{...(3.06)}$$

i.e. *electric energy = electric power × time*

Thus, the total amount of electric energy consumed by an electric circuit depends upon its electric power and the time for which the power is used.

Self-test Questions

What do kilowatt and kilowatt hour represent ?

The SI unit of electric energy is **joule** but another unit called **watt hour** is oftenly used.

1 watt hour = 1 watt × 1 hour

The energy dissipated or consumed in an electric circuit is called one watt hour, if a device of electric power of one watt is used for one hour.

The bigger unit of electric energy is **kilowatt hour (kWh).** It is also known as **Board of Trade Unit (B.O.T.)**.

The energy dissipated or consumed is called one kilowatt hour, if a device of power of one kilowatt is used for one hour.

1 kilowatt hour = 10^3 watt hour

Since $1\text{ kW} = 10^3\text{ J s}^{-1}$ and $1\text{ hour} = 60 \times 60\text{ s}$,

$$1\text{ kWh} = (10^3\text{ J s}^{-1}) \times (60 \times 60\text{ s})$$

or $\mathbf{1\ kWh = 3{\cdot}6 \times 10^6\ J}$

The electric energy consumed in kWh is given by

$$W\text{ (in kWh)} = \frac{V\text{ (in volt)} \times I\text{ (in ampere)} \times t\text{ (in hour)}}{1000}$$

3.04. JOULE'S LAWS OF HEATING EFFECT OF CURRENTS

When a conductor having some resistance is connected to a source of e.m.f., a current flows through it. In fact, free electrons inside the conductor immediately start moving from the end at lower potential to the end at higher potential. This flow of electrons constitutes the electric current. In the course of their motion, the electrons collide against one another and also against the ions and atoms of the conductor. Due to such collisions, the conductor appears to offer some opposition to the motion of electrons *i.e.* to the flow of current. This opposition to the current is termed as resistance of the conductor. Apart from this, at each collision, a part of the kinetic energy of the electron gets converted into heat and the temperature of the conductor increases. It is known as heating effect of the current. The working of electric iron, electric bulb, electric heater, etc are a few examples of heating effects of current.

In 1841, Joule experimentally studied the heating effect of electric current. He found that amount of heat produced in a conductor due to the flow of current is

(i) directly proportional to the square of the current i.e.

$$Q \propto I^2 \qquad \text{...(3.07)}$$

(ii) directly proportional to the resistance of the conductor i.e.

$$Q \propto R \qquad \text{...(3.08)}$$

(iii) directly proportional to the time for which the current is passed i.e.

$$Q \propto t \qquad \text{...(3.09)}$$

Combining factors (3.07), (3.08) and (3.09), we have

$$Q \propto I^2 R\, t$$

$$Q = \frac{I^2 R\, t}{J}, \qquad \text{...(3.10)}$$

where J is a conversion factor, called ***Joule's mechanical equivalent of heat*** and its value is **4·18 J cal^{-1}**. The equation (3.10) is called mathematical form of Joule's laws of heating.

In SI, the heat produced (in joule) due to the flow of current through a resistance is given by

$$Q = I^2 R t \qquad ...(3.11)$$

3.05. EFFICIENCY OF A SOURCE OF E.M.F.

The efficiency of an electric source of e.m.f. is defined as the ratio of the output power to the input power. It is defined by η.

Thus,
$$\eta = \frac{\text{output power}}{\text{input power}} \qquad ...(3.12)$$

Consider that an electric source of e.m.f. E and having internal resistance r is connected to an external resistance R. Then, current flowing through the circuit,

$$I = \frac{E}{R + r} \qquad ...(3.13)$$

Now, input power = E I

The output power of the source is always less than the input power. It is because, the power is wasted in the form of heat developed across the internal resistance of the source. Thus,

output power = $E I - I^2 r$

Therefore, efficiency of the source of e.m.f.,

$$\eta = \frac{E I - I^2 r}{E I} = 1 - \frac{I r}{E}$$

From equation (3.13), substituting for I, we have

$$\eta = 1 - \frac{E}{(R + r)} \cdot \frac{r}{E} = 1 - \frac{r}{R + r}$$

or
$$\eta = \frac{R}{R + r} \qquad ...(3.14)$$

3.06. MAXIMUM POWERTHEOREM

It states that the output power of a source of e.m.f. is maximum, when the external resistance in the circuit is equal to the internal resistance of the source.

Consider that a source of e.m.f. E and having internal resistance r is connected to an external resistance R as shown in Fig. 3.02. The current flowing through the circuit is given by

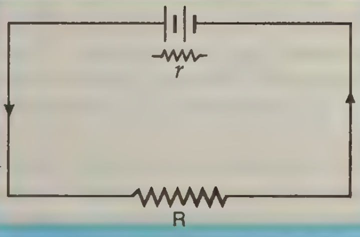

Fig. 3.02

$$I = \frac{E}{R + r}$$

Therefore, output power (electric power dissipated across external resistance) of the source of e.m.f.,

$$P = I^2 R = \left(\frac{E}{R + r}\right)^2 R = \frac{E^2 R}{(R + r)^2} \qquad ...(3.15)$$

For the output power of the source to be maximum,

$$\frac{dP}{dR} = 0 \quad \text{or} \quad \frac{d}{dR}\left[\frac{E^2 R}{(R + r)^2}\right] = 0 \quad \text{or} \quad \frac{d}{dR}\left[\frac{R}{(R + r)^2}\right] = 0$$

or
$$\frac{d}{dR}[R (R + r)^{-2}] = 0 \quad \text{or} \quad [1 \times (R + r)^{-2} + R (-2) (R + r)^{-3}] = 0$$

or
$$(R + r)^{-2} - 2 R (R + r)^{-3} = 0 \quad \text{or} \quad 1 - \frac{2 R}{R + r} = 0$$

or
$$R = r \qquad ...(3.16)$$

Hence, the output power of a source of e.m.f. is maximum, when the external resistance in the circuit is equal to the internal resistance of the source.

Key point

Maximum power is consumed in a circuit, when external resistance in the circuit is equal to the internal resistance of the sourceb of e.m.f.

Maximum output power. The expression for of maximum output power can be obtained by setting r = R in equation (3.15). Therefore, maximum output power,

$$P_{max} = \frac{E^2 R}{(R + R)^2}$$

or
$$P_{max} = \frac{E^2}{4 R} \qquad ...(3.17)$$

3.07. APPLICATIONS OF HEATING EFFECT OF CURRENT

The heating effect of electric current has a wide range of applications in everyday life. Different electric appliances have been designed by making use of heating effect of electric current. A few important applications of this phenomenon are as given below :

1. Incandescent electric bulb. It consists of a filament of fine metallic wire enclosed in a glass blub filled with some inert gas at a suitable pressure. The material of the filament wire has a large value of resistivity and high melting point. Therefore, usually tungsten is used to make the filament of the bulb. When current is passed through the filament, it gets heated to the stage of incandescence. The electric power and voltage specification of the electric bulb are always marked over it. The following points should be noted about the electric bulbs (or electrical appliances in general) of different electric powers :

(i) Since P = V I,

it follows that *current drawn by an electric bulb is directly proportional to its power.*

(ii) Since $P = \frac{V^2}{R}$,

it follows that *resistance of the filament of an electric bulb is inversely proportional to its power.*

The jargon

The emission of light by a substance, when heated to a high temperature, is called incandescence.

2. Electric heating appliances. Electric heater, electric iron, electric immersion rod, electric geyser, electric stove, etc are some of the useful electric appliances, whose working is based on heating effect of electric current. In all such appliances, the heating element used is made of nichrome (an alloy of nickel and chromium). The heating element is made of nichrome for the following reasons :

(i) Its resistivity is large.
(ii) Its melting point is high.
(iii) It does not get oxidised easily, when heated in air.
(iv) It can be easily drawn into wires.

Key point

The filament of an electric bulb or the heating element of an electric appliance is made from a metal (or alloy) possessing large resistivity and high melting point.

3. Arc-lamp. In an arc lamp, light is produced by an electric arc bewteen two electrodes. The most common arc-lamp consists of two carbon electrodes separated by a small gap between them. When voltage is applied across the two electrodes, a spark jumps across the gap between the electrodes and a very intense light is emitted.

4. Electric fuse. It is a safety device used to protect electric installations against overloading. It is also used in electric appliances to save them from getting damaged due to flow of heavy current through them or to prevent electric shock due to live wire coming in contact with the metal casing of the appliance. In the household electric installation and the appliances, the safety fuse is put in series with the live wire from the mains supply.

Watch out !

The load in an electric circuit implies the current drawn circuit from the supply line. When a current flows through the circuit beyond the safe value for it, the current is said to be overloaded !

A safety fuse is basically a piece of wire having a suitable high resistivity and low melting point. The fuse wire is generally prepared from tin-lead alloy (63% tin and 37% lead). When current in the circuit grows to a large value, the fuse wire gets heated, melts and breaks the circuit. The fuse wire of suitable current rating is used in an electric circuit depending on the load in the circuit.

Key point

The safety fuse wire is made from a metal (or alloy) possessing large resistivity and low melting point.

SOLVED NUMERICAL PROBLEMS

Type A. On Electric Power

Problem 3.01. A lamp of 100 W works at 220 volt. What is its resistance and current capacity ?

Sol. Here, power of lamp, P = 100 W ;

operating voltage, V = 220 volt

Now, $P = VI$

Therefore, current capacity of the lamp,

$$I = \frac{P}{V} = \frac{100}{220} = \mathbf{0 \cdot 455\ A}$$

Now, resistance of the lamp, $R = \frac{V^2}{P} = \frac{(220)^2}{100} = \mathbf{484\ \Omega}$

Problem 3.02. Calculate the number of electrons moving per second through the filament of a lamp of 100 watt, operating at 200 volt. Given, charge on electron, $e = 1{\cdot}6 \times 10^{-19}$ C.

Sol. Here, charge on electron, $e = 1{\cdot}6 \times 10^{-19}$ C

Power of the lamp, P = 100 W ;

operating voltage, V = 200 volt

Now, $P = VI$

$$\therefore \quad I = \frac{P}{V} = \frac{100}{200} = 0 \cdot 5\ A$$

Charge passing through the lamp in 1 s,

$$q = I \times t = 0{\cdot}5 \times 1 = 0{\cdot}5\ C$$

Therefore, number of electrons moving through the filament per second,

$$N = \frac{q}{e} = \frac{0 \cdot 5}{1 \cdot 6 \times 10^{-19}} = \mathbf{3 \cdot 125 \times 10^{18}}$$

Problem 3.03. A 60 W – 220 V bulb and 100 W – 220 V bulb are connected in parallel to mains supply. Which bulb will draw more current ?

Ans. Here, $P_1 = 60$ W and $P_2 = 100$ W

When the two bulbs are connected in parallel to the mains supply, the voltage across both of them is same. If I_1 and I_2 are the currents through the two bulbs, then

$$P_1 = V I_1 \quad \text{and} \quad P_2 = V I_2$$

$$\therefore \quad \frac{I_1}{I_2} = \frac{P_1}{P_2} = \frac{60}{100} = 0{\cdot}6 \quad \textit{i.e.} \quad I_2 > I_1$$

Hence, **100 W bulb** draws more current.

Problem 3.04. A 60 W – 220 V bulb and 100 W – 220 V bulb are connected in series to mains supply. (*a*) Which bulb will dissipate more power ? (*b*) Which bulb will glow brighter ?

Sol. Here, $P_1 = 60$ W and $P_2 = 100$ W

(*a*) When the two bulbs are connected in series to the mains supply, the current through both of them will be same. If R_1 and R_2 are the resistances of the two bulbs, then

$$P_1 = I^2 R_1 \quad \text{and} \quad P_2 = I^2 R_2$$

$$\therefore \quad \frac{P_1}{P_2} = \frac{R_1}{R_2} \qquad \ldots(i)$$

$$\text{Now,} \quad R_1 = \frac{V^2}{P_1} = \frac{V^2}{60} \quad \text{and} \quad R_2 = \frac{V^2}{P_2} = \frac{V^2}{100}$$

$$\therefore \quad \frac{R_1}{R_2} = \frac{V^2}{60} \times \frac{100}{V^2} = \frac{5}{3} \qquad \ldots(ii)$$

From equations (*i*) and (*ii*), we have

$$\frac{P_1}{P_2} = \frac{5}{3} \quad \textit{i.e.} \quad P_1 > P_2$$

Hence, when 60 W and 100 W bulbs are connected in series to mains supply, **60 W bulb** will dissipate more power.

(*b*) Since 60 W bulb is dissipating more power, it glows brighter.

Problem 3.05. An electric heater and an electric bulb are rated 500 W-220 V and 100 W-220 V respectively. Both are connected in series to a 220 a.c. mains. Calculate the power consumed by (*i*) the heater and (*ii*) electric bulb.

(*C.B.S.E. 1997*)

Ans. Power of electric heater, $P_1 = 500$ W ;

operating voltage, $V_1 = 220$ V

power of electric bulb, $P_2 = 100$ W ;

operating voltage, $V_2 = 220$ V

Let R_1 and R_2 be resistances of electric heater and bulb respectively. Since $P = \dfrac{V^2}{R}$, we have

$$R_1 = \frac{V_1^2}{P_1} = \frac{(220)^2}{500} = 96{\cdot}8\ \Omega$$

$$\text{and} \quad R_2 = \frac{V_2^2}{P_2} = \frac{(220)^2}{100} = 484\ \Omega$$

When series combination of electric heater and bulb is connected to 220 V main, current in the circuit is given by

$$I = \frac{V}{R_1 + R_2} = \frac{220}{96{\cdot}8 + 484} = 0{\cdot}38 \text{ A}$$

Now, power consumed by heater,

$$P_1' = I^2 R_1 = (0{\cdot}38)^2 \times 96{\cdot}8 = \mathbf{13{\cdot}98\ W}$$

and power consumed by bulb,

$$P_2' = I^2 R_2 = (0{\cdot}38)^2 \times 484 = \mathbf{69{\cdot}89\ W}$$

Problem 3.06. A 100 W - 220 V bulb is connected to 110 V source. Calculate the power consumed by the bulb.

(*P.S.S.C.E. 1999 ; Roorkee 1986*)

Sol. Here, P = 100 W ;

marked operating voltage, V = 200 V

Therefore, resistance of the bulb,

$$R = \frac{V^2}{P} = \frac{(220)^2}{100} = 484\ \Omega$$

Actual operating voltage, $V' = 110$ V

Therefore, power consumed by the bulb,

$$P' = \frac{V'^2}{R} = \frac{(110)^2}{484} = \mathbf{25\ W}$$

Problem 3.07. A voltage stabiliser controls the voltage output to 220 V ± 1%. If a refrigerator rated at 550 W – 220 V is connected to it, what will be the minimum and maximum power consumed by it ?

Sol. Here, power of refrigerator, P = 550 W ;

marked operating voltage, V = 220 V

Therefore, resistance of the refrigerator,

$$R = \frac{V^2}{P} = \frac{(220)^2}{550} = 88\ \Omega$$

The refrigerator will consume maximum power, when supply voltage becomes

$$V_1 = 220 \text{ V} + 1\% = 220 + 2{\cdot}2 = 222{\cdot}2 \text{ V}$$

$$\therefore \quad P_{max} = \frac{V_1^2}{R} = \frac{(222{\cdot}2)^2}{88} = \mathbf{561\ W}$$

The refrigerator will consume minimum power, when supply voltage becomes

$$V_2 = 220 \text{ V} - 1\% = 220 - 2{\cdot}2 = 217{\cdot}8 \text{ V}$$

$$\therefore \quad P_{min} = \frac{V_2^2}{R} = \frac{(217{\cdot}8)^2}{88} = \mathbf{539\ W}$$

Problem 3.08. An electric bulb marked 60 W - 220 V will get fused, if the electric power fed to it becomes 85 W or more. What voltage fluctuation can the bulb withstand.

Sol. Here, P = 60 W ; V = 220 V

Therefore, resistance of the bulb,

$$R = \frac{V^2}{P} = \frac{(220)^2}{60} = 806{\cdot}67\ \Omega$$

Let V′ be the supply voltage, corresponding to which the power fed to the bulb becomes 85 W *i.e.* bulb gets fused. Then,

$$\frac{V'^2}{R} = 85 \quad \text{or} \quad V' = \sqrt{85\,R}$$

$$\text{or} \quad V' = \sqrt{85 \times 806{\cdot}67} = \mathbf{261{\cdot}8\ V}$$

Problem 3.09. A generator is supplying power to a factory by cables of resistance 20 Ω. If the generator is generating 50 kW power at 5000 volt, what is the power received by the factory ? (*P.S.S.C.E. 1996 S*)

Sol. Here, $P = 50 \text{ kW} = 50 \times 10^3$ W ; V = 5000 volt

Therefore, current supplied by the generator,

$$I = \frac{P}{V} = \frac{50 \times 10^3}{5000} = 10 \text{ A}$$

As this current flows through the cables of resistance 20 Ω, a part of power will be wasted in the form of heat energy developed across the cable.

Power wasted across cable,

$$P = I^2 R = (10)^2 \times 20 = 2000 \text{ W} = 2 \text{ kW}$$

Therefore, power received by the factory

$$= P - P' = 50 - 2 = \mathbf{48\ kW}$$

Problem. 3.10. Three resistors R_1, R_2 and R_3 are connected as shown in Fig. 3.03. Each resistor can withstand a maximum power of 18 W (otherwise it will melt). What maximum power, the whole circuit can possess ?

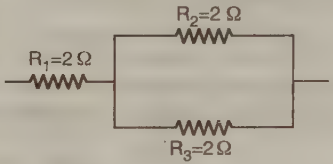

Fig. 3.03

Sol. Here, $R_1 = R_2 = R_3 = 2\ \Omega$

Each of the three resistances can withstand a maximum power of 18 W. If I_{max} is the value of maximum current, which can flow through the resistance without causing it to melt, then

$$I_{max}^2 \times 2 = 18 \quad \text{or} \quad I_{max} = \sqrt{\frac{18}{2}} = 3\text{ A}$$

Electric power of resistance R_1,

$$P_1 = I_{max}^2 \times R_1 = (3)^2 \times 2 = 18\text{ W}$$

The resistance of the parallel combination of R_2 and R_3,

$$R_{23} = \frac{R_2 R_3}{R_2 + R_3} = \frac{2 \times 2}{2+2} = 1\ \Omega$$

Therefore, electric power of the parallel combination of R_2 and R_3,

$$P_{23} = I_{max}^2 \times R_{23} = (3)^2 \times 1 = 9\text{ W}$$

Hence, the maximum power, the circuit can possess

$$= P_1 + P_{23} = 18 + 9 = 27\text{ W}$$

Type B. On Joule's heating effect of currents

Problem 3.11. A power line of resistance 0·5 Ω carries a constant current of 100 A. How much energy is being lost per day in the form of heat in the line ? *(H.S.S.C.E. 2002)*

Sol. Here, $R = 0{\cdot}5\ \Omega$; $I = 100$ A ;

$$t = 1\text{ day} = 24 \times 60 \times 60\text{ s}$$

The amount of heat lost per day in the power line

$$Q = I^2 R t = (100)^2 \times 0{\cdot}5 \times 24 \times 60 \times 60$$
$$= \mathbf{4{\cdot}32 \times 10^8\ J}$$

Problem 3.12. A 10 volt storage battery of negligible internal resistance is connected across a 50 Ω resistor made of alloy manganin. How much heat energy is produced in the resistor in 1 h ? What is the source of this energy ? *(Text Problem)*

Sol. Here, $R = 50\ \Omega$; $V = 10$ volt ; $t = 1\text{ h} = 3600$ s ;

Current in the circuit, $I = \frac{V}{R} = \frac{10}{50} = 0{\cdot}2$ A

Heat produced, $W = I^2 R t = (0{\cdot}2)^2 \times 50 \times 3600 = \mathbf{7200\ J}$

The source of the energy is the **chemical energy** stored in the battery.

Problem 3.13. An electric bulb is marked 100 W – 200 V. If the supply voltage drops to 100 V, what is the heat and light energy produced by the bulb in 10 minutes ? *(P.S.S.C.E. 2002)*

Sol. Here, $P = 100$ W ; $V = 200$ volt

Let R be resistance of the filament of the bulb.

Now, electric power, $P = VI = \frac{V^2}{R}$

Therefore, $R = \frac{V^2}{P} = \frac{(200)^2}{100} = 400\ \Omega$

When the voltage drops to 100 volt, heat and light ene produced by the bulb in 10 minutes is given by

$$W = VIt = \frac{V^2}{R}t = \frac{(100)^2}{400} \times 10 \times 60 = \mathbf{15{,}00}$$

Problem 3.14. Three resistors R_1, R_2 and R_3 connected to a battery of 12 V as shown in Fig. 3. Calculate the heat produced in each of the three resist in 5 minutes.

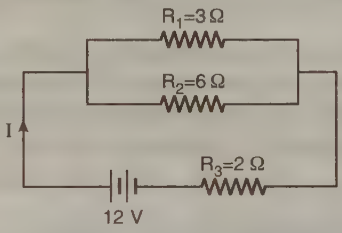

Fig. 3.04

Sol. Here, $R_1 = 3\ \Omega$, $R_2 = 6\ \Omega$; $R_3 = 2\ \Omega$;

$$V = 12\text{ volt and } t = 5\text{ mintues} = 5 \times 60 = 300$$

The resistance of parallel combination of R_1 and R_2

$$R_{12} = \frac{R_1 R_2}{R_1 + R_2} = \frac{3 \times 6}{3+6} = 2\ \Omega$$

Total resistance of the circuit,

$$R = R_{12} + R_3 = 2 + 2 = 4\ \Omega$$

Therefore, current through the circuit,

$$I = \frac{V}{R} = \frac{12}{4} = 3\text{ A}$$

Let I_1 and I_2 be currents through resistances R_1 anc respectively.

Then, $$I_1 = \frac{I \times R_2}{R_1 + R_2} = \frac{3 \times 6}{3+6} = 2\text{ A}$$

and $$I_2 = \frac{I \times R_1}{R_1 + R_2} = \frac{3 \times 3}{3+6} = 1\text{ A}$$

Therefore, heat produced in resistance R_1,

$$Q_1 = I_1^2 R_1 t = (2)^2 \times 3 \times 300 = \mathbf{3600\ J}$$

Heat produced in resistance R_2,

$$Q_2 = I_2^2 R_2 t = (1)^2 \times 6 \times 300 = \mathbf{1800\ J}$$

Heat produced in resistance R_3,

$$Q_3 = I^2 R_3 t = (3)^2 \times 2 \times 300 = \mathbf{5400\ J}$$

Problem 3.15. An electric kettle has two coils. Wl one coil is switched on, it takes 5 mintues to boil water when second coil is switched on, it takes 10 minutes. H long will it take to boil water, when both the coils are u in series ? *(P.S.S.C.E. 20*

Sol. Let R_1 and R_2 be the resistances of the two coils Q be the amount of heat required to boil the water in kettle.

In first case : $t_1 = 5\text{ minutes} = 5 \times 60 = 300$ s

$$\therefore \quad Q = \frac{V^2}{R_1}t_1 = \frac{V^2}{R_1} \times 300$$

or $$R_1 = \frac{300\ V^2}{Q}$$

In second case : $t_2 = 10$ minutes $= 10 \times 60 = 600$ s

$$\therefore \quad Q = \frac{V^2}{R_2} t_2 = \frac{V^2}{R_2} \times 600$$

$$\text{or} \quad R_2 = \frac{600\, V^2}{Q} \qquad \ldots(ii)$$

Let t be the time taken to boil the water, when both the coils are used in series. Then,

$$Q = \frac{V^2}{(R_1 + R_2)} t \quad \text{or} \quad t = \frac{Q}{V^2}(R_1 + R_2)$$

From equation (*i*) and (*ii*), substituting for R_1 and R_2, we have

$$t = \frac{Q}{V^2}\left(\frac{300\, V^2}{Q} + \frac{600\, V^2}{Q}\right) = 900 \text{ s} = \mathbf{15\ minutes}$$

Problem 3.16. A thin metallic wire of resistance 100 ohm is immersed in a calorimeter containing 250 g of water at 10°C and a current of 0· 5 ampere is passed through it for half an hour. If the water equivalent of calorimeter is 10 g, find the rise of the temperature. (*H.S.S.C.E. 1995*)

Sol. Here, $R = 100\ \Omega$; $I = 0{\cdot}5$ A ;

$$t = \frac{1}{2} \text{ h} = \frac{1}{2} \times 60 \times 60 = 1800 \text{ s}$$

Heat produced, $Q = I^2 R t = (0{\cdot}5)^2 \times 100 \times 1800$
$= 4{\cdot}5 \times 10^4$ J

Water equivalent of calorimeter, $w = 10$ g $= 10 \times 10^{-3}$ kg

Mass of water, $m = 250$ g $= 250 \times 10^{-3}$ kg

Let θ be rise in temperature. Since specific heat of water is $4{\cdot}2 \times 10^3$ J kg^{-1} °C^{-1}, we have

$$Q = (m + w)\, c\, \theta$$

$$\text{or} \quad \theta = \frac{Q}{(m + w) \times c}$$

$$= \frac{4{\cdot}5 \times 10^4}{(10 \times 10^{-3} + 250 \times 10^{-3})\, 4{\cdot}2 \times 10^3} = \mathbf{41{\cdot}2°\,C}$$

Problem 3.17. A house is fitted with 10 lamps rated 100 W each, four fans each consuming 0·5 A, an electric kettle of resistance 100 Ω and an electric iron of resistance 121 Ω. If the energy is supplied at 200 V and costs Rs. 2·50 per kWh, calculate the bill for running the appliances for four hours in a day for the month of February, 2000.

Sol. Power of 10 lamps (of 100 W each),

$$10 \times P = 10 \times 100 = 1000 \text{ W}$$

Power of 4 fans (consuming 0·5 A),

$$4 \times V I = 4 \times 200 \times 0{\cdot}5 = 400 \text{ W}$$

Power of the100 Ω electric kettle,

$$\frac{V^2}{R} = \frac{(200)^2}{100} = 400 \text{ W}$$

Power of the 121 Ω electric iron,

$$\frac{V^2}{R} = \frac{(200)^2}{121} = 330{\cdot}58 \text{ W}$$

Total power of the appliances $= 1000 + 400 + 400 + 330{\cdot}58$
$= 2130{\cdot}58$ W $= 2{\cdot}13058$ kW

Number of days in February, 2000 = 29

Therefore, time for which electric energy is used in the month of February, 2000, $= 29 \times 4 = 116$ h

Total electrical energy consumed
$=$ power × time $= 2{\cdot}13058 \times 116 = 247{\cdot}15$ kWh

Cost of electrical energy = Rs. 2·50 per kWh

Therefore, bill for February, 2000 $= 247{\cdot}15 \times 2{\cdot}50$
$=$ **Rs. 617·90**

Problem 3.18. Following electric items are used in a house :

Item	**Number**	**Power**	**Time**
T.V	1	60 W	2 hours a day
Fridge	1	60 W	24 hours a day
Tubes	3	40 W each	4 hours a day (each)
Bulbs	2	60 W each	2 hours a day (each)
Press	1	600 W	$\frac{1}{2}$ hour a day

What will be the electric bill of the house for two months (each month of 30 days), if the rate of power is Rs. 1·35 per unit ? (*H.S.S.C.E. 1994*)

Sol. Electric energy consumed by T.V. per day
$= 60 \times 10^{-3} \times 2 = 0{\cdot}12$ kWh

Electric energy consumed by fridge per day
$= 60 \times 10^{-3} \times 24 = 1{\cdot}44$ kWh

Electric energy consumed by 3 tubes per day
$= 3 \times 40 \times 10^{-3} \times 4 = 0{\cdot}48$ kWh

Electric energy consumed by 2 bulbs per day
$= 2 \times 60 \times 10^{-3} \times 2 = 0{\cdot}24$ kWh

Electric energy consumed by press per day

$$= 600 \times 10^{-3} \times \frac{1}{2} = 0{\cdot}30 \text{ kWh}$$

Total electric energy consumed by all electricals per day
$= 0{\cdot}12 + 1{\cdot}44 + 0{\cdot}48 + 0{\cdot}24 + 0{\cdot}30 = 2{\cdot}58$ kWh

Electric energy consumed in two months (each month of 30 days) $= 2 \times 30 \times 2{\cdot}58 = 154{\cdot}8$ kWh

Cost of electrical energy = Rs. 2·70 per kWh

Therefore, electric bill for 2 months
$= 1{\cdot}35 \times 154{\cdot}8 =$ **Rs. 417·96**

Problem 3.19. An electric power station (100 MW) transmits power to a distant load through long and thin cables. Which of the two modes of transmission would result in lesser power wastage, power transmission at (*i*) 20,000 V or (*ii*) 200 V ? (*Text Problem*)

Sol. Let R be the resistance of the cables.

Here, $P = 100$ MW $= 100 \times 10^6$ W

When transmission is done at $V_1 = 20{,}000$ V : If I_1 is the current through the cables, then

$$I_1 = \frac{P}{V_1} = \frac{100 \times 10^6}{20{,}000} = 5000 \text{ A}$$

Therefore, rate of heat dissipation along the cable at 20,000 V,

$$Q_1 = I_1^2 R = (5000)^2 R = 25 \times 10^6 R \text{ watt}$$

When transmission is done at $V_2 = 200$ V : If I_2 is the current through the cables, then

$$I_2 = \frac{100 \times 10^6}{200} = 5 \times 10^5 \text{ A}$$

Therefore, rate of heat dissipation along the cable at 200 V,

$$Q_2 = I_2^2 R = (5\times10^5)^2 R = 25\times10^{10} R \text{ watt}$$

Hence, there would be lesser power wastage, when transmission is done at **20,000 V.**

Problem 3.20. Two ribbons are given with the following particulars :

Parameter	Constantan	Nichrome
Length (m)	8·456	4·235
Width (mm)	1·0	2·0
Thickness (mm)	0·03	0·06
Resistivity (Ω m)	4.9×10^{-7}	1.1×10^{-6}

For a fixed voltage supply, which of the two ribbons corresponds to a greater rate of heat production ?

(*Text Problem*)

Sol. *For constantan ribbon* :

Resistivity, $\rho_1 = 4.9\times10^{-7}$ Ω m ; length, $l_1 = 8.456$ m ;
width, $b_1 = 1.0$ mm ; thickness, $t_1 = 0.03$ mm

Therefore, area, $A_1 = b_1 \times t_1$

$$= 1.0\times0.03 = 0.03 \text{ mm}^2 = 0.03\times10^{-6} \text{ m}^2$$

Now, $$R_1 = \rho_1 \frac{l_1}{A_1} = \frac{4.9\times10^{-7}\times8.456}{0.03\times10^{-6}}$$

$$= 138.115\ \Omega$$

If V is fixed supply voltage, then rate of heat production,

$$\frac{V^2}{R_1} = \frac{V^2}{138.115} \text{ W} \qquad ...(i)$$

For nichrome ribbon :

Resistivity, $\rho_2 = 1.1\times10^{-6}$ Ω m ; length, $l_1 = 4.235$
width, $b_1 = 2.0$ mm; thickness, $t_1 = 0.06$ mm

$$\therefore \quad A_2 = b_2 \times t_2 = 2.0\times0.06$$

$$= 0.12 \text{ mm}^2 = 0.12\times10^{-6} \text{ m}^2$$

$$\therefore \quad R_2 = \rho_2 \frac{l_2}{A_2} = \frac{1.1\times10^{-6}\times4.235}{0.12\times10^{-6}}$$

$$= 38.821\ \Omega$$

Therefore, rate of heat production,

$$\frac{V^2}{R_2} = \frac{V^2}{38.821} \text{ W}$$

From equations (*i*) and (*ii*), it follows that for a f supply voltage, **nichrome ribbon** corresponds to greater of heat production.

Problem 3.21. An electric motor operating on a 50 V supply draws a current of 12 A. If the efficiency of the m is 30%, estimate the resistance of the windings of the mo

(*P.S.S.C.E. 1992 ; Text Prob*

Sol. Here, V = 50 volt ; I = 12 A

Therefore, power of the electric motor

$$= V\times I = 50\times12 = 600 \text{ W}$$

Since efficiency of the motor is 30%, it dissipates 70 the power across the resistance of the windings of the m

Therefore, power dissipated $= 600\times\frac{70}{100} = 420$ W

If R is resistance of the windings of the motor, ther

$$I^2 R = 420 \quad \text{or} \quad R = \frac{420}{I^2} = \frac{420}{(12)^2} = 2.92\ \Omega$$

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 3.22. A series battery of 6 lead accumulators each of e.m.f. 2·0 volt and internal resistance 0·50 Ω is charged by a 100 V d.c. supply. What series resistance should be used in the charging circuit in order to limit the current to 8·0 A ? Using the required resistor, obtain (*a*) the power supplied by the d.c. source, (*b*) the power dissipated as heat, (*c*) the power supplied by the d.c. energy stored in the battery in 15 minutes. (*Text Problem*)

Sol. For charging the lead accumulators, their positive terminal have to be connected to positive terminal of d.c. supply. Therefore, e.m.f. of the six lead accumulators will oppose the 100 d.c. supply used for charging them.

Hence, net e.m.f. in the circuit = 100 – 6 × 2·0 = 88 volt

Let R be the series resistance that should be used to limit the current to 8·0 A. Therefore,

total resistance of the charging circuit

= R + internal resistance of the six lead accumulators

= R + 6 × 0·50 = R + 3

Now, $$I = \frac{\text{net e.m.f.}}{\text{total resistance}} \quad \text{or} \quad 8 = \frac{88}{R+3}$$

or $$R = 8\ \Omega$$

(*a*) Power supplied by d.c. source

= e.m.f. of source × current supplied

= 100 × 8·0 = **800 W**

(*b*) Power dissipated as heat

$= I^2$ (R + internal resistance of the accumulators)

$= (8.0)^2 \times (8 + 6\times0.50) = 64\times11 =$ **704 W**

(*c*) Power stored in the battery (lead accumulators

= 800 – 704 = **96 W**

Therefore, energy stored in the battery in 15 minut

= 96 × 15 × 60 = **86400 J**

Problem 3.23. Power from a 64 V d.c. supply goe charge a battery of 8 lead accumulators each of e. 2·0 V and internal resistance 1/8 Ω. The charging cur also runs an electric motor placed in series with the bat If the resistance of the windings of the motors is 7·0 Ω the steady supply current is 3·5 A, obtain (*a*) the me nical energy yielded by the motor and (*b*) the chem energy stored in the battery during charging in 1 h.

(*Text Prob*

Sol. Here, e.m.f. of d.c. supply = 64 V ;

e.m.f. of each of the 8 lead accumulators = 2·0 V

Total e.m.f. of 8 accumulators = 2·0 × 8 = 16·0 V

Internal resistance of each lead accumulator $= \frac{1}{8}$ Ω

Total internal resistance, $r = \frac{1}{8}\times8 = 1.0\ \Omega$

Resistance of the windings of the motor, R = 7·0 Ω

Steady current in the circuit, I = 3·5 A

Rate of consumption of energy in the circuit

= 64 × 3·5 = 224 W

Rate of storing chemical energy in the battery

= 16 × 3·5 = 56 W

Rate of energy dissipation as heat in the circuit

$$= I^2 (R + r) = (3{\cdot}5)^2 \times (7{\cdot}0 + 1{\cdot}0) = 98 \text{ W}$$

Rate of mechanical energy yielded by motor

$$= 224 - (56 + 98) = 70 \text{ W}$$

(*a*) Mechanical energy yielded by motor in 1 h

$$= 70 \times 3600 = \mathbf{252000 \text{ J}}$$

(*b*) Chemical energy stored in the battery during charging in 1 h

$$= 56 \times 3600 = \mathbf{201600 \text{ J}}$$

Problem 3.24. A battery of internal resistance r (= 4 Ω) is connected to the network of resistanes as shown in Fig. 3.05. What must be the value of R, so that maximum power is delivered to the network ? What is the maximum power ? *(I.I.T. 1995)*

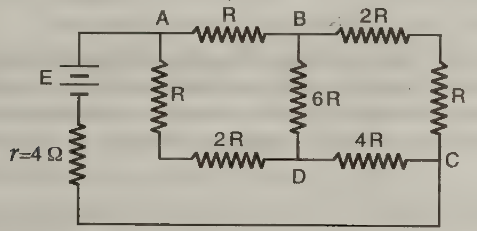

Fig. 3.05

Sol. The given network is equivalent to the circuit shown in Fig. 3.06.

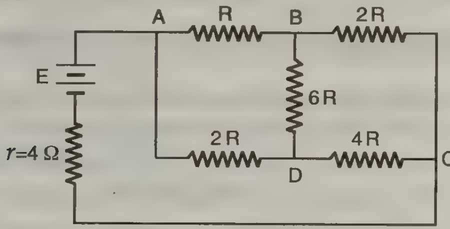

Fig. 3.06

It follows that the circuit represents a Wheatstone bridge, where

Further, resistance in arm AB (P arm) = R

resistance in arm BC (Q arm) = 2 R,

resistance in arm AD (R arm) = 2 R

and resistance in arm DC (S arm) = 4 R

Further, as $\frac{P}{Q} = \frac{R}{S}$, it is a balanced Wheatstone bridge. Since the resistance 6 R connected across the points B and D is ineffective, the circuit shown in Fig. 3.06 is equivalent to the circuit shown in Fig. 3.07.

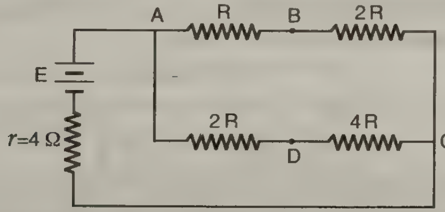

Fig. 3.07

Therefore, effective resistance of path ABC,

$$R_1 = R + 2\,R = 3\,R$$

and effective resistance of path ADC,

$$R_2 = 2\,R + 4\,R = 6\,R$$

If R_{12} is equivalent resistance of R_1 and R_2, then

$$R_{12} = \frac{R_1\,R_2}{R_1 + R_2} = \frac{3\,R \times 6\,R}{3\,R + 6\,R} = 2\,R$$

If E is e.m.f. of the battery, then current in the main circuit,

$$I = \frac{E}{R_{12} + r} = \frac{E}{2\,R + 4}$$

Therefore, electric power of the network of resistances,

$$P = I^2\,R_{12} = \left(\frac{E}{2\,R + 4}\right)^2 \times 2\,R \qquad \text{...}(i)$$

According to maximum power theorem, maximum power will be delivered to the network, when

resistance of network = internal resistance of battery

i.e. when $R_{12} = r$ or $2\,R = 4$

or $R = 2\,\Omega$

Setting R = 2 Ω in equation (*i*), we have maximum power of the network,

$$P_{max} = \left(\frac{E}{2 \times 2 + 4}\right)^2 \times 2 \times 2 = \frac{\mathbf{E^2}}{\mathbf{16}}$$

Problem 3.25. A 24 V battery of internal resistance 4 Ω is connected to a variable resistor. At what value of the current drawn from the battery is the rate of heat produced in the resistor maximum ? *(Text Problem)*

Sol. Here, e.m.f. of battery = 24 V ;

internal resistance, $r = 4\,\Omega$

Let R be the resistance of the variable resistor, at which rate of heat produced (power) is maximum.

Then, total resistance in the circuit $= R + r = R + 4$

Therefore, current drawn from the battery

$$I = \frac{\text{e.m.f.}}{\text{total resistance}} = \frac{24}{R + 4}$$

Therefore, rate at which heat is produced,

$$P = I^2\,R = \left(\frac{24}{R + 4}\right)^2 R$$

For rate of heat produced to be maximum, $\frac{dP}{dR} = 0$

$$\text{or} \qquad \frac{d}{dR}\left[\left(\frac{24}{R + 4}\right)^2 R\right] = 0$$

$$\text{or} \qquad \frac{d}{dR}\left[576\,R\,(R + 4)^{-2}\right] = 0$$

$$\text{or} \qquad \frac{d}{dR}\left[R\,(R + 4)^{-2}\right] = 0$$

$$\text{or} \quad R\,(-2)\,(R + 4)^{-3} + (R + 4)^{-2} = 0$$

$$\text{or} \qquad -2\,R\,(R + 4)^{-1} + 1 = 0 \quad \text{or} \quad \frac{2\,R}{R + 4} = 1$$

$$R = 4\;\Omega$$

Therefore, the required value of the current drawn from the battery,

$$I = \frac{24}{R + 4} = \frac{24}{4 + 4} = \mathbf{3\text{ A}}$$

It may be noted that the rate of heat produced is maximum, when external resistance is equal to internal resistance of the battery.

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 3.01. How is energy related to electric power ?

Ans. Electric energy = electric power × time

Q. 3.02. What is practical unit of electric energy ?

Ans. The practical unit of electric energy is kilowatt hour (kWh).

Q. 3.03. What is B.O.T ? Convert it into joule. *(H.S.S.C.E. 1996)*

Ans. B.O.T. (Board Of Trade unit) is unit of electric power. It is also called kilowatt hour (kWh).

Now, $1 \text{ B.O.T.} = 1 \text{ kWh} = 1 \text{ kW} \times 1 \text{ hour}$
$= (10^3 \text{ J s}^{-1}) \times 3600 \text{ s} = \mathbf{3{\cdot}6 \times 10^6 \text{ J}}$

Q. 3.04. Calculate the number of joule in 1 kWh. *(H.P.S.S.C.E. 1999 ; H.S.S.C.E. 1996)*

Ans. $1 \text{ kWh} = 1 \text{ kW} \times 1 \text{ hour} = (10^3 \text{ J s}^{-1}) \times 3600 \text{ s}$
$= 3{\cdot}6 \times 10^6 \text{ J}$

Q. 3.05. How many kilowatt hours (kWh) are there in one joule ? *(C.B.S.E. 1999 S)*

Ans. From VSQ 3.04, it follows that

$$1 \text{ J} = \frac{1}{3{\cdot}6 \times 10^6} \text{ kWh}$$

Q. 3.06. Distinguish between kilowatt and kilowatt hour.

Ans. Kilowatt is unit of electric power, while kilowatt hour is unit of electric energy.

Q. 3.07. Which consumes more electric energy in a given time – a 1000 watt heater or a 1000 watt bulb ?

Ans. Both consume same amount of electric energy in a given time.

Q. 3.08. Calculate the current through a lamp of 60 W, operating at 220 V. *(H.P.S.S.C.E. 1998)*

Ans. Here, P = 60 W ; V = 220 volt

Now, $$I = \frac{P}{V} = \frac{60}{220} = 0{\cdot}273 \text{ A}$$

Q. 3.09. What is the resistance of 1 kW heater marked for 220 V ? *(H.P.S.S.C.E. 1999 S ; H.S.S.C.E. 1998)*

Ans. Here, P = 1 kW = 1000 W ; V = 220 volt

Now $$R = \frac{V^2}{P} = \frac{(220)^2}{1000} = 48{\cdot}4 \, \Omega$$

Q. 3.10 Which has a greater resistance–1 kW electric heater or a 100 W filament bulb both marked for 220 V ? *(C.B.S.E. 2001 S)*

Ans. Now, $P = \frac{V^2}{R}$ or $R = \frac{V^2}{P}$

Here, power of electric heater, $P_1 = 1 \text{ kW} = 1000 \text{ W}$;
power of bulb = 100 W

Therefore, resistance of heater, $$R_1 = \frac{(220)^2}{1000} = 48{\cdot}4 \, \Omega$$

and resistance of bulb, $$R_2 = \frac{220^2}{100} = 484 \, \Omega$$

Hence, the **100 W bulb** has more resistance than the electric heater.

Q. 3.11. Which lamp has greater resistance, a 100 W and 60 W lamp when connected to the same source of supply ? *(C.B.S.E. 1999 S, 1998 ; H.S.S.C.E. 1999 S ; H.S.S.C.E. 1992)*

Ans. Now, $R = \frac{V^2}{P}$

Therefore, resistance of 100 W bulb,

$$R_1 = \frac{(220)^2}{100} = 484 \, \Omega$$

and resistance of 60 W bulb, $$R_2 = \frac{(220)^2}{60} = 806{\cdot}67 \, \Omega$$

Thus, the **60 W bulb** has greater resistance.

Q. 3.12. Two heating coils, one of fine wire and other of thick wire, made of same material and of the same length, are connected one by one to a source of electricity. Which one of the two coils will produce heat at a greater rate ? *(C.B.S.E. 1999 S)*

Ans. Since $R \propto \frac{1}{A}$, the heating coil made of thick wire possesses lesser resistance.

As $P = \frac{V^2}{R}$ *i.e.* $P \propto \frac{1}{R}$, heat will be produced at a greater rate in the coil of lesser resistance *i.e.* in the coil made of **thick wire**.

Q. 3.13. The maximum power dissipated in a 10,000 Ω resistor is 1 W. What is the maximum current ? *(I.S.C.E. 1993)*

Ans. Here, $P_{max} = 1 \text{ W}$; $R = 10{,}000 \, \Omega$

Now, $P_{max} = I_{max}^2 \, R$

$$\therefore \quad I_{max} = \sqrt{\frac{P_{max}}{R}} = \sqrt{\frac{1}{10000}} = \mathbf{0{\cdot}01 \text{ A}}$$

Q. 3.14. How much charge flows through a 250 V –1000 W heater in one minute ? *(I.S.C.E. 1996)*

Ans. Here, P = 1000 W ; V = 250 volt ;
$t = 1 \text{ minute} = 60 \text{ s}$

Now, $$I = \frac{P}{V} = \frac{1000}{250} = 4 \text{ A}$$

Therefore, charge flowing in 1 minute,
$q = I\,t = 4 \times 60 = \mathbf{240 \text{ C}}$

Q. 3.15. What is the largest voltage you can safely put across a 98 Ω – 0·5 W resistor ? *(I.S.C.E. 1997)*

Ans. Here, P = 0·5 W ; R = 98 Ω

Now, $$P = \frac{V^2}{R}$$

$$\therefore \quad V = \sqrt{PR} = \sqrt{0{\cdot}5 \times 9{\cdot}8} = \mathbf{7 \text{ V}}$$

Q. 3.16. A current of 5·0 A flows through an electric press of resistance 11 Ω. Calculate the energy consumed by the press in 5 minutes. *(C.B.S.E. 1994)*

Ans. Here, I = 5·0 ; R = 11 Ω ;
$t = 5 \text{ minutes} = 5 \times 60 = 300 \text{ s}$

Electric energy consumed in 5 minutes
$= I^2 R t = (5{\cdot}0)^2 \times 11 \times 300 = \mathbf{8{\cdot}25 \times 10^4 \text{ J}}$

Q. 3.17. Nichrome and copper wires of the same length and same radius are connected in series. Current I is passed through them. Why does the nichrome wire get heated first? *(C.B.S.E. 2001 S)*

Ans. The nichrome and copper wires are of same length and same radius but the resistivity of nichrome is large as compared to that of copper. Due to this, the resistance of nichrome wire is very large in comparison to that of copper wire. When two wires are connected in series, the same amount of current flows through each of them. Since heat produced in a wire is directly proportional to its resistance, **nichrome** wire gets heated first.

Q. 3.18. Three bulbs 40 W, 60 W and 100 W are connected to 220 V mains. Which bulb will glow brightly, if they are joined in series ? *(H.P.S.S.C.E. 2001)*

Sol. From the relation, $R = \dfrac{V^2}{P}$, it follows that resistance of 40 W bulb will be maximum. When the bulbs are connected in series, the same amount current flows through all the bulbs. Since heat produced and hence brightness of a bulb is directly proportional to the resistance of its filament, **40 W** bulb will glow brightly.

Q. 3.19. A heater joined in series with 60 W bulb is connected to the mains. If 60 W bulb is replaced by a 100 W bulb, will the rate of heat produced by the heater be more, less or remain the same ? *(C.B.S.E. 2001 (S))*

Sol. The resistance of 100 W bulb is less than that of 60 W bulb. Therefore, when 60 W bulb is replaced by 100 W bulb, the current through the circuit will increase. As a result, heater will produce **more** heat, when 60 W bulb is replaced by 100 W bulb.

Q. 3.20. What are the characteristics of a fuse wire ?

Ans. A fuse wire is made of a material having high resistivity and low melting point. However, the value of its melting point is slightly above the temperature that the wire attains, when the current equal to maximum safe value flows through the fuse wire.

Q. 3.21. What is a safety fuse ? Explain its function. *(P.S.S.C.E. 1999)*

Ans. Refer to section 3.07.

Q. 3.22. What are the characteristics of the filament of a heater ?

Ans. The material of the filament of a heater has high resistivity and high melting point.

Q. 3.23. Name a few practical applications of heating effect of current.

Ans. The appliances, such as (*i*) electric lamp, (*ii*) electric heater, (*iii*) electric iron, (*iv*) electric geyser, (*v*) safety fuse, etc are based on heating effect of current.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 3.01. Define the terms electric energy and electric power. Give their units. *(H.S.S.C.E. 1992)*

Ans. For definition of electric energy and electric power, refer to sections 3.03 and 3.02.

The unit of electric energy is kilowatt hour and that of electric power is kilowatt.

Q. 3.02. Explain, why heat is produced in a conductor, when an electric current is passed through it.

Ans. The flow of electric current through a conductor means the flow of electrons through it. In the course of their motion, the electrons collide against one another and also against the atoms of the conductor. At each collision, a part of kinetic energy of the electron gets converted into heat, thereby causing a rise in the temperature of the conductor.

Q. 3.03. State Joule's heating law. *(H.P.S.S.C.E. 2001)*

Ans. Refer to section 3.04.

Q. 304. State and explain Joule's law for the rate of production of heat in a conductor carrying current. *(H.S.S.C.E. 2002)*

Ans. Refer to section 3.04.

Q. 3.05. A given potential difference is applied to a good conductor and a bad conductor of same dimension. Which one shall produce more heat and why ?

Ans. If a good conductor and a bad conductor have same dimensions, then resistance of the good conductor will be less than that of the bad conductor. When a given potential difference is applied to each of them, current in case of conductor will be more. Since heat produced $Q \propto I^2$, it follows that heat produced in case of **good conductor** will be more.

Q. 3.06. Two resistors of 2 Ω and 4 Ω are connected in parallel to a constant d.c. voltage. In which resistor is more heat produced ? *(C.B.S.E. 1998 S)*

Ans. Here, $R_1 = 2\ \Omega\ ;\ R_2 = 4\ \Omega$

Let V be the applied d.c. voltage. When the two resistors are connected in parallel to the d.c. supply of voltage V, the potential difference across both the resistances will be same *i.e.* V. If H_1 and H_2 are heat produced in the two resistors in 1 s, then

$$H_1 = \frac{V^2}{R_1} \text{ and } H_2 = \frac{V^2}{R_2}$$

$$\therefore \quad \frac{H_1}{H_2} = \frac{V^2}{R_1} \times \frac{R_2}{V^2} = \frac{R_2}{R_1} = \frac{4}{2} = 2$$

Therefore, heat produced in **2 Ω** resistance will be more.

Q. 3.07. A 6 V storage battery of negligible internal resistance is connected across a 60 Ω resistor. How much heat is produced in the resistor in 2 hours ? What is the source of energy ? *(H.S.S.C.E. 2002, 1996)*

Ans. Here, $V = 6$ volt ; $R = 60\ \Omega$; $t = 2\text{ h} = 7200$ s

Heat energy produced in 1 h

$$= V\,I\,t = \frac{V^2}{R}\,t = \frac{(6)^2}{60} \times 7200 = \mathbf{4320\ J}$$

The source of heat energy is the **chemical energy** stored in the storage battery.

Q. 3.08. A heater coil is cut into two parts and only one of them is used in the heater. What is the ratio of the heat produced by this half coil to that by the original coil ?

Ans. Suppose that the resistance of the heater coil is R and it is used on a supply line of V volt.

Heat energy produced by the heater coil in time t,

$$Q = \frac{V^2}{R} t$$

The resistance of the one half of the coil $= \frac{R}{2}$

Heat energy produced by the half coil,

$$Q_2 = \frac{V^2}{R/2} t = \frac{2V^2}{R} t$$

$$\therefore \quad \frac{Q_2}{Q_1} = \frac{2V^2}{R} t \Big/ \frac{V^2}{R} t = 2$$

Q. 3.09. Three equal resistors connected in series across a source of e.m.f. together dissipate 10 W of power. What would be the power dissipated, if the same resistors are connected in parallel across the same source of e.m.f. ?

Ans. Let the e.m.f. of the source be V and the resistance of each resistor be R.

Resistance of the three resistors in series = 3 R

As power consumed by the three resistors in series is 10 W, we have

$$\frac{V^2}{3R} = 10$$

$$\text{or} \quad \frac{V^2}{R} = 30 \qquad \ldots(i)$$

Resistance of the three resistors in parallel $= \frac{R}{3}$

Therefore, power consumed by parallel combination of the resistors, $P = \frac{V^2}{R/3} = \frac{3V^2}{R}$

Using equation (*i*), we have

$$P = 3 \times 30 = 90 \text{ W}$$

Q. 3.10. In a house having 220 V-line, the following appliances are operating : a 60 W bulb, a 1000 W heater and a 40 W radio. Calculate (*a*) the current drawn by heater and (*b*) the current passing through fuse for this line. (*M.N.R. 1989*)

Ans. Here, V = 220 volt

Power rating of bulb, $P_1 = 60$ W;

power rating of heater, $P_2 = 1000$ W ;

power rating of radio, $P_3 = 40$ W

(*a*) Current drawn by heater $= \frac{P_2}{V} = \frac{1000}{220} = \frac{50}{11}$ A

Current drawn by bulb $= \frac{P_1}{V} = \frac{60}{220} = \frac{3}{11}$ A

Current drawn by radio $= \frac{P_3}{V} = \frac{40}{220} = \frac{2}{11}$ A

(*b*) Current passing through fuse for the line

$$= \frac{50}{11} + \frac{3}{11} + \frac{2}{11} = 5 \text{ A}$$

Q. 3.11. A toaster produces more heat than a light bulb, when connected in parallel. Which has greater resistance ? (*C.B.S.E. 1999 S*)

Ans. Let R_1 and R_2 be resistances of the toaster and the light bulb respectively. If V is the voltage applied across their parallel combination, then

heat produced per second in toaster, $P_1 = \frac{V^2}{R_1}$

and heat produced per second in light bulb, $P_2 = \frac{V^2}{R_2}$

Since toaster produces more heat than the light bulb,

$$P_1 > P_2$$

$$i.e. \quad \frac{V^2}{R_1} > \frac{V^2}{R_2} \quad \text{or} \quad R_1 < R_2$$

i.e. the resistance of the **light bulb** is more than that of the toaster.

Q. 3.12. Find the cost of electricity for running an electric motor of 1 h.p. for 5 hours a day @ Rs. 1·50 per unit for the month of November. (*H.S.S.C.E. 1995*)

Ans. Here, power of electric motor,

$$P = 1 \text{ h.p.} = 746 \text{ W} = 0{\cdot}746 \text{ kW}$$

Number of hours for which motor is run

$$= 5 \times 30 = 150 \text{ h}$$

Electrical energy consumed by the motor

$$= 0{\cdot}746 \times 150 = 111{\cdot}9 \text{ kWh}$$

Cost of running the motor $= 111{\cdot}9 \times 1{\cdot}50 =$ **Rs. 167·85**

Q. 3.13. The element of a heater is very hot, while the connecting wires carrying the current are cold. Why ?

Ans. The same current passes through the element of the heater and the connecting wires. The element of the heater becomes very hot as its resistance is very high as compared to that of the connecting wires.

Q. 3.14. Explain why an electric bulb becomes dim, when an electric heater in parallel circuit is switched on. Why dimness decreases after some time ?

Ans. The electric power of a heater is more than that of a bulb. Since power of an appliance is inversely proportional to its resistance $\left(P \propto \frac{1}{R}\right)$, the resistance of heater is less than that of the electric bulb.

When the heater connected in parallel to the bulb is switched on, it draws more current in the circuit due to its lesser resistance. As a result, current through the electric bulb decreases and it becomes dim.

When the heater coil becomes sufficently hot, its resistance becomes more and then it draws a little lesser current. As a result of it, the current through the electric bulb recovers. It is for this reason that after some time, the dimness of the bulb decreases.

Q. 3.15. Water boils in an electric kettle in time *t*, after it has been switched on. Using the same main supply, it is desired to make water boil in a lesser time. Should the length of the heating element be increased or decreased ?

Ans. Let l, A and ρ be the length, area of cross-section and resistivity of the material of the heating element. Then, its resistance is given by

$$R = \rho \frac{l}{A}$$

If V is the supply voltage, then heat required to boil the water in kettle,

$$Q = \frac{V^2 t}{R} = \frac{V^2 A t}{\rho l}$$

$$\text{or} \quad l = \frac{V^2 A t}{Q \rho} \quad \text{or} \quad l \propto t$$

Therefore, if water is to be boiled in lesser time, the ength of the heating element should be **decreased**.

Q. 3.16. What is the difference between heating wire nd a fuse wire ? *(H.S.S.C.E. 2001)*

Ans. A heating wire is made of a material having high alues of both resisitivity and melting point. The high value f resistivity ensures the production of a large amount of heat, whereas the high value of melting point saves it from melting.

On the other hand, a fuse wire is made of a material having a suitable high resisitivity but low melting point. When the current in electric circuit exceeds a safe limit, the high value of resistivity results in the production of heat and the low value of melting point causes it to melt. It, thus, saves the electrical appliances from gettting damaged.

TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 3.01. Prove that total power consumed by a number of electrical appliances (when connected in parallel) s equal to the sum of the powers consumed by individual ppliances.

Ans. Consider three electrical appliances of powers $_1$, P_2 and P_3. Let R_1, R_2 and R_3 be their respective resistances. ince appliances are connected in parallel, their total esistance is given by

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} \quad \text{...}(i)$$

Suppose that the appliances are operated at the voltage . Multiplying both sides of equation (*i*) by V^2, we have

$$\frac{V^2}{R} = \frac{V^2}{R_1} + \frac{V^2}{R_2} + \frac{V^2}{R_3}$$

or $\quad P = P_1 + P_2 + P_3$

Hence, total power consumed by the three appliances is qual to the sum of the powers of the individual appliances.

Q. 3.02. A frill of 50 bulbs joined in series is connected to mains. On getting one bulb fused, the remaining 9 bulbs are again put in series and connected to the same ain supply. Will the light emitted by the frill increase or ecrease ?

Ans. Let R be the resistance of the 50 bulbs, when joined n series.

Therefore, power of the frill of 50 bulbs, $P = \frac{V^2}{R}$,

here V is the voltage of mains supply.

When one bulb gets fused, the resistance of remaining 9 bulbs of the frill will decrease. Suppose that it becomes R'.

Therefore, power of the frill of 49 bulbs, $P' = \frac{V^2}{R'}$,

Since $R' < R$, it follows that $\frac{V^2}{R'} > \frac{V^2}{R}$. Hence, the light mitted by the frill of 49 bulbs will be **more**.

Q. 3.03. The maximum power rating of a 30 Ω resistor is 2·0 kW. (That is, this is the maximum power the esistor can dissipate as heat without melting or changing n some other undesirable way). Would you connect this esistor directly across a 300 V d.c. source of negligible nternal resistance ? Explain your answer.

(H.S.S.C.E. 1997 S ; Text Question)

Ans. Here, R = 30 Ω ;

Power rating of resistor P = 2·0 kW

If the resistor is connected to 300 V d.c., then rate of dissipation of heat,

$$P = \frac{V^2}{R} = \frac{300^2}{30} = 3000 \text{ W} = 3\cdot0 \text{ kW}$$

Since power rating of the resistor is 2·0 kW, it will melt out. Hence, it **should not be connected** to the 300 V d.c. directly.

Q. 3.04. A current is passed through a steel wire, heating it to red hot. The half of the wire is immersed in cold water. Which half of the wire will heat up more and why ?

Ans. The part of the steel wire outside the cold water will heat up more. The reason is that the temperature of the part of the wire outside the water will be more than that of the part inside the water. Since resistance of the wire increases with temperature, the resistance of the part of the wire outside the water will become more than that of the part inside the water. Since same current is flowing through the two parts, more heat will be produced in the part outside the water.

Q. 3.05. A 60 W electric bulb connected (*a*) in series (*b*) in parallel with a room heater is further connected across the mains. If 60 W bulb is now replaced by 100 W bulb in each case, will the heat produced by heater be smaller, remain the same or be larger and why ?

(C.B.S.E. Sample Q. Paper)

Ans. Let V be mains supply voltage and R be the resistance of room heater.

Resistance of 60 W bulb, $R_1 = \frac{V^2}{P} = \frac{V^2}{60}$

Resistance of 100 W bulb, $R_2 = \frac{V^2}{P} = \frac{V^2}{100}$

Obviously, R_2 is less than R_1.

(a) When bulb is connected in series with the room heater :

Current flowing through heater and 60 W bulb,

$$I_1 = \frac{V}{R + R_1}$$

Current flowing through heater and 100 W bulb,

$$I_2 = \frac{V}{R + R_2}$$

Now heat produced is directly proportional to square of the current flowing through the heater. Since R_2 is less than R_1, I_2 will be greater than I_1 and consequently heat produced by the heater will be **more**, when 60 W bulb connected in series is replaced by 100 W bulb.

(b) When bulb is connected in parallel with the room heater : When bulb and heater are connected in parallel to the mains, the potential difference across each is equal to the mains supply voltage. Therefore, current and consequently heat produced by the heater will remain **unchanged** on replacing 60 W bulb by 100 W bulb.

Q. 3.06. A storage battery of e.m.f. E is shorted by an external circuit first with a resistance R_1 and then with

a resistance R_2. Find the value of the internal resistance of the battery, if the quantities of heat liberated by the battery in the two cases are same.

Ans. Let r be internal resistance of the battery.

Heat produced in time t, when shorted with the resistance R_1,

$$Q_1 = \left(\frac{E}{R_1 + r}\right)^2 R_1 t \qquad \text{...}(i)$$

Also, heat produced in time t, when shorted with the resistance R_2,

$$Q_2 = \left(\frac{E}{R_2 + r}\right)^2 R_2 t \qquad \text{...}(ii)$$

Since same quantity of heat is produced in two cases,

$$\left(\frac{E}{R_1 + r}\right)^2 R_1 t = \left(\frac{E}{R_2 + r}\right)^2 R_2 t$$

$$\text{or} \quad R_1 (R_2 + r)^2 = R_2 (R_1 + r)^2 \quad \text{or} \quad r = \sqrt{R_1 R_2}$$

Q. 3.08. A steel wire has a resistance twice as great as a copper wire. Which wire will liberate more heat : (*a*) in parallel ; (*b*) in series, when the combination is connected to a battery ?

Ans. Let 2 R and R be the resistances of the steel and copper wires respectively.

(a) When the two wires are connected in parallel : Let I_1 and I_2 be currents through the steel and copper wires respectively [Fig. 3.08].

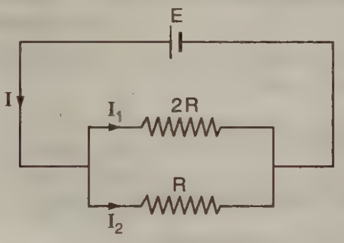

Fig. 3.08

$$\text{Then,} \qquad I_1 = \frac{E}{2R} \text{ and } I_2 = \frac{E}{R}$$

Heat produced in steel wire in time t,

$$Q_1 = I_1^2 (2R) t = \left(\frac{E}{2R}\right)^2 (2R) t = \frac{E^2}{2R} t$$

Heat produced in copper wire in time t,

$$Q_2 = I_2^2 R t = \left(\frac{E}{R}\right)^2 R t = \frac{E^2}{R} t$$

As $Q_2 > Q_1$, **copper wire** will liberate more heat.

(b) When two wires are connected in series : Let I be the current flowing through the series combination of the two wires [Fig. 3.09].

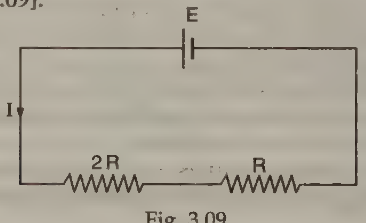

Fig. 3.09

$$\text{Then,} \qquad I = \frac{E}{2R + R} = \frac{E}{3R}$$

Heat produced in steel wire in time t,

$$Q_1 = I^2 (2R) t = \left(\frac{E}{3R}\right)^2 (2R) t = \frac{2}{9}\frac{E^2}{R} t$$

Heat produced in copper wire in time t,

$$Q_2 = I^2 R t = \left(\frac{E}{3R}\right)^2 R t = \frac{1}{9}\frac{E^2}{R} t$$

As $Q_1 > Q_2$, **sheet wire** will liberate more heat.

Q. 3.08. A dry cell of e.m.f. 1·5 volt and interr resistance 0·10 Ω is connected across a resistance series with a very low resistance ammeter. When the circ is switched on, the ammeter reading settles to a steady val of 2·0 A. What is the steady

(*a*) rate of chemical energy consumption of the cel

(*b*) rate of energy dissipation inside the cell,

(*c*) rate of energy dissipation inside the resistor an

(*d*) power output of the source ? *(Text Questic*

Sol. Here, V = 1·5 volt ; r = 0·10 Ω ; I = 2·0 A

Let R be the external resistance. Then,

$$I = \frac{V}{R + r} \quad \text{or} \quad R + r = \frac{V}{I} = \frac{1{\cdot}5}{2{\cdot}0} = 0{\cdot}75\,\Omega$$

$$\text{or} \quad R = 0{\cdot}75 - 0{\cdot}10 = 0{\cdot}65\,\Omega$$

(*a*) Rate of consumption of chemical energy of the c

$V \times I = 1{\cdot}5 \times 2{\cdot}0 = \mathbf{3{\cdot}0\ W}$

(*b*) Rate of energy dissipation inside the cell,

$I^2\, r = (2{\cdot}0)^2 \times 0{\cdot}10 = \mathbf{0{\cdot}4\ W}$

(*c*) Rate of energy dissipation inside the resistor,

$I^2\, R = (2{\cdot}0)^2 \times 0{\cdot}65 = \mathbf{2{\cdot}6\ W}$

(*d*) Power output of the source

= total power

– rate of energy dissipiation inside the c

$= 3{\cdot}0 - 0{\cdot}4 = \mathbf{2{\cdot}6\ W}$

Q. 3.09. Two wires made of tinned copper havi identical cross-section (= 10^{-6} m^2) and lengths 10 and 15 cm are to be used as fuses. Show that the fuses w melt at the same value of current in each case.

(Text Questi

Ans. Let there be a wire of length l, radius r and mater of resistivity ρ.

Now, resistance of the wire, $R = \rho \dfrac{l}{A} = \rho \dfrac{l}{\pi r^2}$

Suppose that a current I is passed through the wire.

Heat produced per second $= I^2 R = I^2 \rho \dfrac{l}{\pi r^2}$

The hot wire will heat radiate from its surface to t surroundings. Let the rate of loss of heat due to radiation fr the surface of the wire per unit its surface area be equal to

Neglecting the area of the end faces,

$$\text{surface area of wire} = 2 \pi r l$$

Therefore, heat radiated per second by the wire

$$= 2 \pi r l H$$

As current flows through the wire, heat is produced a its temperature keeps on rising. At the same time, heat is l to the surroundings due to radiation at a rate, which increa with the increase in temperature of the wire. The wire w be saved from melting, if its temperature rises say up to θ (below the melting point of the material of the wire), at which the rate of production of heat in the wire just becomes equal to the rate of loss of heat due to radiation from it. Therefore, in equilibrium,

heat lost per second = heat produced per second

$$2\pi r l H = I^2 \rho \frac{l}{\pi r^2}$$

or
$$H = I^2 \cdot \frac{\rho}{2\pi^2 r^3}$$

It follows that rate of loss of heat (which depends upon the temperature of the wire) does not depend upon length of the wire. Hence, fuses of different length will melt at the same value of current in each case.

Q. 3.10. A fuse with a circular cross-sectional radius of 0·15 mm blows at 15 A. What should be the radius of cross-section of a fuse made of the same material, which will blow at 30 A ? *(Text Question)*

Ans. From conceptual SAQ 3.09, it follows that

$$\frac{I^2}{r^3} = \frac{2\pi^2 H}{\rho} = \text{constant}$$

If I_1 and I_2 are current ratings of the fuse wires (currents at which, the fuse wires will blow) of radii r_1 and r_2, then

$$\frac{I_1^2}{r_1^3} = \frac{I_2^2}{r_2^3} \quad \text{or} \quad r_2 = r_1\left(\frac{I_2}{I_1}\right)^{2/3}$$

Here, $I_1 = 15$ A ; $r_1 = 0{\cdot}15$ mm and $I_2 = 30$ A

$$\therefore \quad r_2 = 0{\cdot}15 \times \left(\frac{30}{15}\right)^{2/3} = 0{\cdot}15 \times 2^{2/3} = 0{\cdot}15 \times 1{\cdot}5874$$

$$= 0{\cdot}238 \text{ mm}$$

Q. 3.11. A nichrome heating element across 230 V supply consumes 1·5 kW of power and heats up to a temperature of 750°C. A tungsten bulb across the same supply operates at a much higher temperature of 1600°C in order to be able to emit light. Does it mean that the tungsten bulb necessarily consume greater power ? *(Text Question)*

Ans. As worked out in conceptual SAQ 3.09, the steady temperature of a current carrying wire depends on rate of loss of heat (which depends on surface area, emissivity, etc) from the wire in addition to the power consumed. Therefore, it does not necessarily mean that tungsten bulb working at higher temperature consumes greater power.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. What do you understand by heating effect of current ? Explain its cause. *(H.P.S.S.C.E. 2002)*
2. Prove that heat produced in good conductor is given by
$$H = \frac{I^2 R t}{4{\cdot}2} \text{ (in cal)},$$
where the symbols used have usual meanings.
3. Prove that electric energy (W) consumed in a conductor is given by the formula :
$$W = I^2 R t$$
4. A potential difference V is applied across a resistance R. Find a relation for the power consumed. *(P.S.S.C.E. 1992)*
5. Obtain an expression for the heat produced in a given conductor on passing current. *(H.S.S.C.E. 1999)*
6. Define electric power and electric energy. Give their SI units. *(P.S.S.C.E. 1993)*
7. Derive Joule's law for heating effects of currents. What are the units of electric power and electric energy ?
8. State and explain Joule's law of heating effects of current. *(H S S C E 1997)*

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. (*a*) Explain, why heat is produced, when a current passes through a resistance. Obtain an expression for the heat produced, when current is passed through a conductor.
(*b*) Define electric power and electric energy. Define their SI units.
2. (*a*) State and explain Joule's laws for heating effect of current.
(*b*) Explain in brief three important applications of heating effect of current.

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Electric power

1. A lamp of 40 W works at 200 volt. What is its resistance and current capacity ? **[Ans.** 1000 Ω, 0·2 A]
2. How many 60 watt bulbs may be safely run on 220 V using a 5 A fuse ? *(C.B.S.E. 1999)* **[Ans.** 18]
3. An electric heater consists of 10 m long nichrome wire of $2{\cdot}5 \times 10^{-6}$ m^2 cross-sectional area. Calculate the wattage of the heater, when the potential difference across the heater is 200 V. Given that resistivity of nichrome = $1{\cdot}1 \times 10^{-6}$ Ω m. **[Ans.** 9·091 kW]
4. Three equal resistances connected in series across a source of e.m.f. consumes 20 watt. If the same resistances are connected in parallel across the same source of e.m.f., what would be power dissipated ? *(P.S.S.C.E. 1999 ; C.B.S.E. 1999)* **[Ans.** 180 W]

Type B. On Joule's heating effect of current

5. A heating element of resistance 40 ohm is connected to 200 V supply ? How much heat will be produced in one minute ? *(P.S.S.C.E. 1999)* **[Ans.** 6×10^4 J]
6. An electric bulb is marked 100 W-200 V. If the supply voltage drops to 110 V, how much heat and light energy is produced by the bulb in half hour ? *(P.S.S.C.E. 1998)* **[Ans.** 54450 J]
7. An electric bulb is marked 100 W-230 V. If the supply voltage drops to 115 V, what is the heat and light energy produced by the bulb in 20 minutes ? *(P.S.S.C.E. 1997 S ; Text Problem)* **[Ans.** 30,000 J]
8. Calculate the amount of heat produced per second (in calories), when a bulb of 100 W, 220 V glows assuming that only 20% of electric energy is converted into light ($J = 4{\cdot}2$ J cal^{-1}). *(H.S.S.C.E. 2001)* **[Ans.** 19·05 cal]

9. In the circuit shown in Fig. 3.10, if the heat developed in 4 Ω resistance due to the current flowing through it is 40 cal s^{-1}, find the rate at which heat is produced in 2 Ω resistance. [Ans. 80 cal s^{-1}]

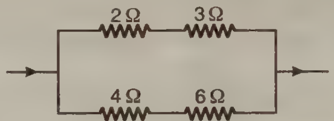

Fig. 3.10

10. Three resistors R_1, R_2 and R_3 each of 240 Ω are connected across a 120 V suppy as shown in Fig. 3.11. Find (*a*) the potential difference across each resistor and (*b*) the total heat developed across the three resistors in 1 minute. [Ans. $V_1 = 80$ V, $V_2 = V_3 = 40$ V ; 2400 J]

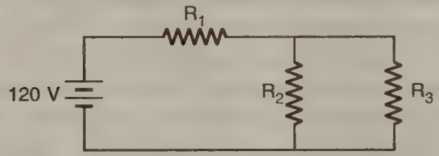

Fig. 3.11

11. A 2·5 kW heater is used for 4 hours daily. If electric energy is being sold at the rate of Rs. 2·5 per kWh, what will be the cost of the bill for a month ? (*P.S.S.C.E. 1999*) [Ans. Rs. 750]

12. What will be the cost of running 500 W heater for 20 hours at the rate of Re. 2·40 per unit ? [Ans. Rs. 24]

13. By mistake, a 100 watt electric lamp remains switched on for 30 days. What is the loss, if electricity costs Re. 3·00 per kilowatt hour ? [Ans. Rs. 216]

14. What is the cost of electrically heating 50 litres of water from 40°C to 100°C at Re. 2·50 per kWh ? Given, J = 4·2 J cal^{-1}. [Ans. Rs. 8·75]

15. A room heater is marked 1000 watt and 220 volt. Calculate (*a*) the current it draws (*b*) its resistance (*c*) cost of running it for 12 hours at the rate of Rs. 2·50 per unit. [Ans. 4·545A, 48·4 Ω, Rs. 30]

16. A house is fitted with two electric lamps, each of 100 W ; one heater of resistance 110 Ω and two fans, each consuming 0·25 A. If electric energy is supplied at 200 V and each appliance works for 5 hours a day, find the monthly bill at the rate of Rs. 3·0 per kWh. (*P.S.S.C.E. 1998 S*) [Ans. Rs. 308·58]

17. A house is fitted with eight lamps (each of 40 watt) and two fans, each taking a current of 0·25 ampere. The energy is supplied at 220 volt. If the lamps are lighted for 3 hours a day and the fans work for 6 hours a day, find the bill for 30 days. The cost of energy is at the rate of Rs. 2·40 per kWh. [Ans. Rs. 116·64]

18. A house is fitted with 10 lamps of 60 W each, 10 fans consuming 0·5 A each and an electric kettle of resistance 110 Ω. If the energy is supplied at 220 V and costs Rs 2·50 per kWh ; calculate bill for 10 days, if all the appliances are used for 6 hours daily. (*H.P.S.S.C.E. 1998 S*) [Ans. Rs. 321]

19. A house is fitted with 20 lamps rated 100 W each, 10 fans consuming 0·5 A each and electric kettle of resistance 100 ohm. Electricity is supplied at 220 V and electrical energy is sold at Re. 2·50 per kWh. Calculate the bill for 10 days, if all the appliances are used for 6 hours daily. [Ans. Rs. 537·60]

20. Calculate the amount of water at 26°C that will converted into steam by an electric heater of power 2 kW one hour. Given, specific heat of water = 4·2 × 10^3 J kg^{-1}°C and latent heat of steam = 2·26 × 10^6 J kg^{-1}. [Ans. 2·8 k

21. A copper electric kettle of 1 kg contains 900 g of water 20°C. It takes 12 minutes to raise the temperature to 100° If electric energy is supplied at 210 volt, calculate t strength of the electric current, assuming 10% of the he is wasted. Take specific heat of copper = 0·1. [Ans. 2·47

22. A heater coil is rated 100 W, 200 V. It is cut into two identi parts. Both parts are connected together in parallel to t same source of 200 V. Calculate the energy liberated p second in the new combination. (*C.B.S.E. 200* [Ans. 400

23. Two electric lamps are rated at 220 V- 40 W and 220 V- W. Find the heat generated in each per second, when th are connected in series across 220 V line. J = 4·2 J cal^{-1}. [Ans. 3·429 cal ; 2·286 c

24. For what value of load resistance, the power transfer maximum, when two identical cells, each of e.m.f. E a internal resistance *r* are connected in (*a*) series and parallel. [Ans. (*a*) 2 *r* (*b*) *r*/

25. How will you connect 36 cells, each of internal resistar 1·5 Ω so as to get maximum power out across a load 6 Ω ? [Ans. Three rows, each row containing 12 cel

26. An electric motor operates on a 50 V supply and draw current of 15 A. If the motor yields a mechanical power 150 W, estimate the power dissipated across its windin Also, find the efficiency of the motor ? [Ans. 600 W ; 20

MISCELLANEOUS PROBLEMS

27. A cell sends a current through a resistance R_1 for time *t* is, then, used to send current through another resistar for the same time *t*. If the heat developed in the two cas is same, then calculate the internal resistance of the ce [Ans. $\sqrt{R_1 \, R}$

28. Water boils in an electric kettle in 15 minutes, after it h been switched on. If the length of the heating element decreased to two thirds of its original length calculate t time in which the same amount of water will boil, wh kettle is connected to the same supply. [Ans. 10 mi

29. An electric kettle heater has two coils. When one coil switched on, the water in the kettle begins to boil after minutes and when the other is switched on the wa begins to boil after 30 minutes. How soon will the wa in the kettle begin to boil, if both the coils are connect (*a*) in series ; (*b*) in parallel ? [Ans. (*a*) 45 min ; (*b*) 10 m

30. Twenty one electric bulbs are connected in series to 2 V supply. After one bulb is fused, the remaining 20 bul are again connected in series to the same supply. By wh precentage will the illumination of (*a*) one bulb change a (*b*) all the bulbs change ? [Ans. (*a*) 10·25% (*b*) 5

31. A room is lit with a 60 W lamp. The voltage in the mai is 220 V. A 1000 W heater is, then, switched on. If t resistance of the wires connecting the electrical devices the room with the mains is 10 Ω, by how much will t voltage supplied to the lamp be changed, when the hea is switched on ? [Ans. 36·83

32. A line having a total resistance of 0·2 Ω delivers 10 kW 220 V to a small factory. What is the efficiency transmission ? [Ans. 96

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Proceed as in solved problem no. 3.01.

2. Current drawn by 60 W bulb, $I = \frac{P}{V} = \frac{60}{220}$ A

Therefore, number of bulbs that can be run on 5 A fuse,

$$n = \frac{\text{current rating of fuse}}{I} = \frac{5}{60/220} = 18 \cdot 33$$

i.e. $n = \mathbf{18}$

3. Now, $R = \rho \frac{l}{A} = 1 \cdot 1 \times 10^{-6} \times \frac{10}{2 \cdot 5 \times 10^{-6}} = 4 \cdot 4\,\Omega$

Also, $P = \frac{V^2}{R} = \frac{(200)^2}{4 \cdot 4} = 9091\text{ W} = \mathbf{9{\cdot}091\ kW}$

4. Let V be e.m.f. of the source and R, the resistance each of the three resistors.

When resistors are connected in series :

$$R_s = R + R + R = 3R$$

Now, $P = \frac{V^2}{R_s}$ or $20 = \frac{V^2}{3R}$

or $\frac{V^2}{R} = 60$ ...(*i*)

When resistors are connected in parallel :

$$R_p = \frac{R}{3}$$

Now, $P' = \frac{V^2}{R_p}$ or $P' = \frac{V^2}{R/3} = 3\frac{V^2}{R}$

or $P' = 3 \times 60 = \mathbf{180\ W}$

5. $Q = \frac{V^2}{R} t = \frac{(200)^2}{40} \times 60 = \mathbf{6 \times 10^4\ J}$

6. Proceed as in solved problem no. 3.13.

7. Proceed as in solved problem no. 3.13.

8. Power of bulb, P = 100 W

Therefore, electric energy consumed per second = 100 J

Electric energy converted into heat,

$$Q = \frac{100 \times 80}{100} = 80\text{ J} = \frac{80}{4 \cdot 2} = \mathbf{19{\cdot}05\ cal}$$

9. Resistance of series combination of 2 Ω and 3 Ω resistors,

$$R_1 = 2 + 3 = 5\,\Omega$$

Also, resistance of series combination of 4 Ω and 6 Ω resistors,

$$R_2 = 4 + 6 = 10\,\Omega$$

Let I be the total current in the circuit. Then, part of current through R_1,

$$I_1 = \frac{I \times R_2}{R_1 + R_2} = \frac{I \times 10}{5 + 10} = \frac{2I}{3}$$

and part of current through R_2,

$$I_2 = \frac{I \times R_1}{R_1 + R_2} = \frac{I \times 5}{5 + 10} = \frac{I}{3}$$

Now, heat produced per second in 2 Ω resistor,

$Q_1 \propto I_1^2 \times 2$ ...(*i*)

and heat produced per second in 4 Ω resistor.

$Q_2 \propto I_2^2 \times 4$ ...(*ii*)

$\therefore \quad \frac{Q_1}{Q_2} = \frac{I_1^2 \times 2}{I_2^2 \times 4}$ or $\frac{Q_1}{40} = \frac{(2I/3)^2 \times 2}{(I/3)^2 \times 4}$

or $\mathbf{Q_1 = 80\ cal\ s^{-1}}$

10. (*a*) Total resistance of the circuit,

$$R = R_1 + \frac{R_2 \times R_3}{R_2 + R_3} = 240 + \frac{240 \times 240}{240 + 240}$$

$$= 240 + 120 = 360\Omega$$

Therefore, current in the main circuit,

$$I = \frac{V}{R} = \frac{120}{360} = \frac{1}{3}\text{ A}$$

and potential difference across R_1,

$$V_1 = IR_1 = \frac{1}{3} \times 240 = \mathbf{80\ V}$$

Since $R_2 = R_3$, current equal to $\frac{I}{2}$ *i.e.* $\frac{1}{6}$ A will flow through each of the two resistances.

Therefore, potential difference across R_2 or R_3 *i.e.*

$$V_2 = V_3 = \frac{1}{6} \times 240 = \mathbf{40\ V}$$

(*b*) Heat developed across the three resistors in 1 minute,

$$Q = I^2 R t = \left(\frac{1}{3}\right)^2 \times 360 \times 60 = \mathbf{2400\ J}$$

11. Energy consumed in 1 day = 2·5 × 4 = 10 kWh

Energy consumed in 1 month = 10 × 30 = 300 kWh

Cost of monthly bill = 300 × 2·5 = **Rs. 750**

12. Proceed as in problem no. 11.

13. Proceed as in problem no. 11.

14. Volume of water, V = 50 litre = 50×10^3 cm^3

Mass of water, $m = V\rho = 50 \times 10^3 \times 1 = 50 \times 10^3$ g

$= 50$ kg

Heat required to raise the temperature of water from 40°C to 100°C

$$Q = mc(\theta_2 - \theta_1)$$

Specific heat of water = 1 cal g^{-1} °C^{-1}

$= 4{\cdot}2 \times 10^3$ J kg^{-1} °C^{-1}

$\therefore \quad Q = 50 \times 4{\cdot}2 \times 10^3 \times (100 - 40) = 1{\cdot}26 \times 10^7$ J

Now, 1 kWh = $3{\cdot}6 \times 10^6$ J

$$\therefore \quad Q = \frac{1 \cdot 26 \times 10^{-7}}{3 \cdot 6 \times 10^6} = 3 \cdot 5\text{ kWh}$$

Cost of electricity = 3·5 × 2·50 = **Rs. 8·75**

15. Here, P = 1000 W, V = 220 V

(*a*) $I = \frac{P}{V} = \frac{1000}{220} = \mathbf{4{\cdot}545\ A}$

(*b*) $R = \frac{V}{I} = \frac{220 \times 220}{1000} = \mathbf{48{\cdot}4\ \Omega}$

(*c*) Energy consumed in 12 hours,

$$Q = P \times t = \frac{1000}{1000} \times 12 = 12\text{ kWh}$$

Cost of electricity = 12 × 2·50 = **Rs. 30**

16. Proceed as in solved problem no. 3.17.

17. Proceed as in solved problem no. 3.17.

18. Proceed as in solved problem no. 3.17.

19. Proceed as in solved problem no. 3.17.

20. Heat produced by heater in 1 hour,

$$Q = P \times t = 2 \times 10^3 \times 60 \times 60$$

or $Q = 7{\cdot}2 \times 10^6$ ...(*i*)

Suppose that this amount of heat Q can convert mass *m* (in kg) of water at 26°C into steam.

Then, $Q = mc(\theta_2 - \theta_1) + mL = m[c(\theta_2 - \theta_1) + L]$

$= m[4{\cdot}2 \times 10^3 (100 - 26) + 2{\cdot}26 \times 10^6]$

or $Q = 2{\cdot}57 \times 10^6\, m$ ...(*ii*)

From equations (*i*) and (*ii*), we have

$2{\cdot}57 \times 10^6\, m = 7{\cdot}2 \times 10^6$ or $\mathbf{m = 2{\cdot}8\ kg}$

21. Mass of kettle, M = 1 kg = 1000 g ;

mass of water, *m* = 900 g

specific heat of copper, *c* = 0·1,

specific heat of water, *c'* = 1,

$\theta_1 = 20$°C and $\theta_2 = 100$°C

Therefore, amount of heat required to heat water in kettle from 20°C to 100°C,

$$Q = M\,c\,(\theta_2 - \theta_1) + m\,c'\,(\theta_2 - \theta_1)$$
$$= (M\,c + m\,c')\,(\theta_2 - \theta_1)$$

or $Q = (1000 \times 0{\cdot}1 + 900 \times 1) \times (100 - 20)$
$= 8 \times 10^4 \text{ cal} = 8 \times 4{\cdot}2 \times 10^4 \text{ J}$

Let I be the current passed through the kettle. Therefore, heat produced by kettle in 12 minutes,

$$Q' = V\,I\,t = 210 \times I \times 12 \times 60 \text{ J}$$

As 10% of heat produced is wasted, useful heat produced,

$$Q = \frac{Q' \times 90}{100}$$

or $$Q = \frac{210 \times I \times 12 \times 60 \times 90}{100} \text{ J} \quad ...(ii)$$

From equations (*i*) and (*ii*) we have

$$\frac{210 \times I \times 12 \times 60 \times 90}{100} = 8 \times 4{\cdot}2 \times 10^4$$

or $I = 2{\cdot}47$ **A**

22. Resistance of heater coil, $R = \frac{V^2}{P} = \frac{(200)^2}{100} = 400\ \Omega$

When coil is cut into two parts, resistance of each of the two parts,

$$R_1 = R_2 = \frac{400}{2} = 200\ \Omega$$

Resistance of the parallel combination of two parts of the coil,

$$R_p = \frac{R_1 R_2}{R_1 + R_2} = \frac{200 \times 200}{200 + 200} = 100\ \Omega$$

Therefore, energy liberated per second by the parallel combination,

$$P = \frac{V^2}{R_p} = \frac{(200)^2}{100} = \mathbf{400\ W}$$

23. Proceed as in solved problem no. 3.05.

24. (*a*) When cells are connected in series,
total internal resistance = $2\,r$
For maximum power transfer,
$R = 2\,r$
(*b*) When cells are connected in parallel,
total internal resistance = $r/2$
For maximum power transfer,
$$R = \frac{r}{2}$$

25. Suppose that the 36 cells are arranged in *m* rows, each row containing *n* cells. Then,

$$m\,n = 36 \quad ...(i)$$

Let *r* be internal resistance each cell.

Total internal resistance of the cells = $\frac{n\,r}{m}$

The grouping cells will deliver maximum current and hence maximum power, when
total internal resistance = external resistance

or $\frac{n\,r}{m} = R$ or $\frac{n \times 1{\cdot}5}{m} = 6$ or $n = 4\,m$

Substituting for *n* in equation (*i*), we have

$m \times 4\,m = 36$ or $m = 3$

Also, $n = 4\,m = 4 \times 3 = \mathbf{12}$

26. Total power of the motor, $P = V\,I = 50 \times 15 = 750$ W
Mechanical power of the motor = 150 W
Therefore, power dissipated across windings of motor
$P' = 750 - 150 =$ **600 W**

Efficiency of motor = $\frac{P'}{P} \times 100 = \frac{150}{750} \times 100 =$ **20%**

27. Let E be e.m.f. and *r*, the internal resistance of the cell. Heat produced in resistance R_1 in time *t*,

$$Q_1 = \left(\frac{E}{R_1 + r}\right)^2 R_1\,t$$

Also, heat produced in resistance R_2 in time *t*,

$$Q_2 = \left(\frac{E}{R_2 + r}\right)^2 R_2\,t$$

Since $Q_1 = Q_2$, we have

$$\left(\frac{E}{R_1 + r}\right)^2 R_1\,t = \left(\frac{E}{R_2 + r}\right)^2 R_2\,t$$

or $$\frac{R_1}{(R_1 + r)^2} = \frac{R_2}{(R_2 + r)^2}$$

or $R_1\,(R_2 + r)^2 = R_2\,(R_1 + r)^2$

On simplifying, we get

$$r = \sqrt{\mathbf{R_1\,R_2}}$$

28. Let R be resistance of the heating element of the kettle a
Q be the amount of heat required to boil the water in t
kettle. Then,

$$Q = \frac{V^2}{R}\,t$$

In first case :

$$Q = \frac{V^2}{R} \times 15 \times 60 \quad ...$$

In second case : When length of the heating element
decreased to two thirds of its original length, resistance
heating element becomes,

$$R' = \frac{2\,R}{3}$$

Suppose that water now boils in time *t*. Then,

$$Q = \frac{V^2}{R'} \times t = \frac{V^2}{2\,R/3} \times t$$

or $$Q = \frac{1{\cdot}5\,V^2}{R}\,t \quad ...($$

From equations (*i*) and (*ii*), we have

$$\frac{1{\cdot}5\,V^2}{R}\,t = \frac{V^2}{R} \times 15 \times 60$$

or $$t = \frac{15 \times 60}{1{\cdot}5} = 600\ \text{s} = \frac{600}{60} = \mathbf{10\ minutes}$$

29. (*a*) Proceed as in solved problem no. 3.15.

(*b*) For first coil, $Q = \frac{V^2}{R_1} \times 15 \times 60$

or $$R_1 = \frac{V^2 \times 900}{Q}$$

and for second coil, $Q = \frac{V^2}{R_2} \times 30 \times 60$

or $$R_2 = \frac{V^2 \times 1800}{Q}$$

The resistance of the parallel combination of two coils,

$$R = \frac{R_1\,R_2}{R_1 + R_2}$$

If water, now, boils in time *t*, then

$$Q = \frac{V^2}{R}\,t = \frac{V^2(R_1 + R_2)}{R_1\,R_2}\,t = V^2\left(\frac{1}{R_1} + \frac{1}{R_2}\right)t$$

Substituting for R_1 and R_2, we get

$$Q = V^2\left(\frac{Q}{V^2 \times 900} + \frac{Q}{V^2 \times 1800}\right)t$$

or $$\frac{1}{t} = \frac{1}{900} + \frac{1}{1800}$$

or $$t = \frac{1800 \times 900}{1800 + 900} = 600 \text{ s} = \textbf{10 minutes}$$

30. Let R be resistance of each bulb. Then,
resistance of series combination of all the 21 bulbs = 21 R

Current through the bulbs, $I = \frac{220}{21\,R}$

Illuminating power of one bulb,

$$P_1 = I^2\,R = \left(\frac{220}{21\,R}\right)^2 R = \frac{109 \cdot 75}{R}$$

Illuminating power of all the bulbs,

$$P = 21 \times P_1 = \frac{21 \times 109 \cdot 75}{R} = \frac{2304 \cdot 75}{R}$$

When one bulb gets fused :
Resistance of series combination of all the 20 bulbs = 20 R

Current through the bulbs, $I' = \frac{220}{20\,R}$

Illuminating power of one bulb,

$$P_1' = I_1'\,R = \left(\frac{220}{20\,R}\right)^2 R = \frac{121}{R}$$

Illuminating power of all the bulbs,

$$P' = 20 \times P_1' = \frac{20 \times 121}{R} = \frac{2420}{R}$$

(*i*) % increase in illuminating power of one bulb,

$$\frac{P_1' - P_1}{P_1} \times 100 = \frac{121/R - 109 \cdot 75/R}{109 \cdot 75/R} \times 100$$

$$= \mathbf{10 \cdot 25\ \%}$$

(*ii*) % increase in illuminating power of all the bulbs,

$$\frac{P' - P}{P} \times 100 = \frac{2420/R - 2304 \cdot 75/R}{2304 \cdot 75/R} \times 100$$

$$= \mathbf{5\ \%}$$

31. Resistance of bulb, $R_1 = \frac{V^2}{P_1} = \frac{(220)^2}{60} = 806 \cdot 67\ W$

Resistance of heater, $R_2 = \frac{V^2}{P_2} = \frac{(220)^2}{1000} = 48 \cdot 4\ \Omega$

Resistance of the wires connecting the devices to the mains, $R_0 = 10\ \Omega$

Before the heater is switched on :
Current in the circuit,

$$I = \frac{V}{R_1 + R_0} = \frac{220}{806 \cdot 67 + 10} = 0 \cdot 2694\ A$$

Voltage drop across the connecting wires,

$$V_0 = I\,R_0 = 0 \cdot 2694 \times 10 = 2 \cdot 694\ V$$

After the heater is switched on :
Current in the circuit,

$$I' = \frac{V}{\dfrac{R_1 \times R_2}{R_1 + R_2} + R_0} = \frac{220}{\dfrac{806 \cdot 67 \times 48 \cdot 4}{806 \cdot 67 + 48 \cdot 4} + 10} = 3 \cdot 9525\ A$$

Voltage drop across the connecting wires

$$V_0' = I'\,R_0 = 3 \cdot 9525 \times 10 = 39 \cdot 525\ V$$

Therefore, change in voltage supplied to the lamp,

$$V_0' - V_0 = 39 \cdot 525 - 2 \cdot 694 = \mathbf{36 \cdot 83\ V}$$

32. Actual power delivered to factory, P = 10 kW
Current along the transmission line,

$$I = \frac{P}{V} = \frac{10 \times 10^3}{220} = 45 \cdot 455\ A$$

Resistance of power line, $R = 0 \cdot 2\ \Omega$
Therefore, loss of power along the transmission line

$$= I^2\,R = (45 \cdot 455)^2 \times 0 \cdot 2 = 413 \cdot 2\ W = 0 \cdot 4132\ kW$$

Hence, power supplied to transmission line,

$$P' = 10 + 0 \cdot 4132 = 10 \cdot 4132\ kW$$

Therefore, efficiency of transmission line,

$$\eta = \frac{P}{P'} \times 100 = \frac{10}{10 \cdot 4132} \times 100 = \mathbf{96\%}$$

CHAPTER
4

Chemical Effects of Curren

4.01. CHEMICAL EFFECT OF ELECTRIC CURRENTS

The chemical effects of electric current were studied by Faraday in 1833. When electric current is passed through a conductor, it gets heated. The magnetic field is also produced around a current carrying conductor. However, no chemical effect is produced, when current is passed through a conductor. The chemical effects of current may be observed in liquids. If electric current is passed through a liquid, it may or may not allow the passage of current through it. In fact, on the basis of their electric behaviour, the liquids may be divided into three classes :

(i) The liquids which do not allow current to pass through them. For example, distilled water, vegetable oil, etc.

(ii) *The liquids which allow current to pass through them but do not dissociate into ions.* For example, mercury.

(iii) *The liquids which allow current to pass through them by dissociating into ions.* For example, salt solutions, acids and bases.

The liquids, whcih dissociate into ions on passing current through them are called ***electrolytes*** *and the process of dissociation of a liquid into ions on passing current through it, is called* ***electrolysis****.*

Therefore, passage of electric current through the electrolytes produces chemical effect.

Key point

**When current passes through a metal
conductor, heating and magnetic effe
occur. No chemical effect is produced
a metallic conductor on passing curre
through it. Only a liquid may sho
chemical effects of electric curre
through it.**

4.02. ELECTROLYTE

The substances, which dissociate into ions and when in solution form, allow electric current to pass through them, are called ***electrolytes.*** For example, acids, bases, acidulated water, salt solutions, such as copper sulphate, silver nitrate, etc.

On the basis of their behaviour towards the passage of electric current, the electrolytes are of the following two types :

1. Strong electrolytes. *Those electrolytes, which are more or less completely ionised in their solutions, are called strong electrolytes.* For example, HCl, NaOH and NaCl.

2. Weak electrolytes. *Those electrolytes, which are ionised to a small extent in their solutions, are called weak electrolytes.* For example, NH_4Cl, CH_3COOH and $H_2 O_3$.

Key point

**The electrolytes are also known
conductors of second kind.**

4.03. ELECTROLYSIS

The process of liberating free elements from an electrolytic solution, when electric current is passed through it, is called ***electrolysis.***

When an electrolyte, such as copper sulphate ($CuSO_4$) is dissolved in water, it dissociates into ions as below :

$$CuSO_4 \longrightarrow Cu^{++} + SO_4^{--}$$

Consider that the copper sulphate solution is taken in a vessel and current is passed through it by using two electrodes and a source of e.m.f. The electrode, through which the current enters the electrolytic solution, is called ***anode,*** while the other electrode, through which current leaves, is called ***cathode.***

On passing current, Cu^{++} ions drift to the cathode, while SO_4^{--} ions towards the anode. At the cathode, Cu^{++} ions discharge themselves and copper atoms are liberated at the cathode.

The vessel, in which electrolysis is carried out is called ***voltameter.*** It is also called an ***electrolytic cell.***

4.04. THEORY OF ELECTROLYTES

An atom, a group of atoms or radical having charge is called an ion.

Substances like sodium chloride (NaCl), copper sulphate ($CuSO_4$), silver nitrate ($AgNO_3$), etc, when dissolved in water dissociate into ions. The dissociation of these substances into ions may be represented as below :

$$\mathrm{NaCl} \longrightarrow \mathrm{Na}^+ + \mathrm{Cl}^-$$
$$\mathrm{CuSO_4} \longrightarrow \mathrm{Cu}^{++} + \mathrm{SO_4^{--}}$$
$$\mathrm{AgNO_3} \longrightarrow \mathrm{Ag}^+ + \mathrm{NO_3^-}$$

If an atom, a molecule or a radical has electrons less than what it would have in its normal state, it is called a ***positive ion***. The positive ions are called ***cations*** ; as during electrolysis, they would collect at the cathode. On the other hand, if an atom, a molecule or a radical has electrons more than what it would have in its normal state, it is called a ***negative ion***. The negative ions collect at the anode during electrolysis and accordingly, they are called ***anions***. Let us first understand the mechanism of dissociation of a substance into ions.

In crystalline NaCl, Na^+ and Cl^- ions have large force of attraction between them. To remove Na^+ and Cl^- ions from each other, an energy of 7·9 eV per molecule is required. The average thermal agitation energy is of the order of 0·03 eV and it is thus insufficient to separate Na^+ and Cl^- ions, when it is in crystalline state.

Water has dielectric constant equal to 80. When sodium chloride is dissolved in water, Na^+ and Cl^- ions find themselves in water as continuous medium. Due to this, the potential energy of the sodium chloride molecule reduces by a factor of 80 and the average thermal agitation energy becomes sufficient to take Na^+ and Cl^- ions away from electric field. Electrolytes conduct electricity but their conductivity is very low. At room temperature, the conductivity of an electrolyte is about 10^{-5} to 10^{-6} times that of a good metallic conductor. It is because of the following three reasons :

Key point

An electrolyte dissociates into ions on being dissolved in water due to the reason that high value of the dielectric constant of water reduces the force of attraction between its positive and negative ions.

1. The number of free ions per unit volume in an electrolyte is quite smaller than the number of free electrons per unit volume in a metallic conductor.
2. In comparison to electrons, ions have very large mass. Therefore, when electric field is applied, they drift much more slowly than electrons.
3. Since an electrolytic solution is quite dense, the ions experience more difficulty to drift through it.

Key point

The conductivity of electrolytes is very small as compared to that of a metallic conductor due to the fact that number density of free ions in them is very small as compared to number density of free electrons in a metallic conductor.

Water also dissociates into positive and negative ions as represented below :

$$\mathrm{H_2O} \longrightarrow \mathrm{H}^+ + \mathrm{OH}^-$$

In pure water, its dissociation into ions is of a very low degree (about one part in 10^7). As such its conductivity is very low. However, when an acid or an alkali is added to water, its conductivity increases by a very large amount. Thus, water containing say a few drops of an acid also behaves as an electrolyte.

4.05. ELECTROLYSIS OF COPPER SULPHATE

A copper voltameter is used to carry out the electrolysis of copper sulphate solution. It consists of a glass vessel, which contains two copper electrodes A and C and the copper sulphate solution as the electrolyte. A battery, a rheostat, an ammeter and a one-way key are connected across the two copper electrodes A and C as shown in Fig. 4.01. The rheostat is used to adjust the current in the circuit, while he ammeter is used to measure the current. The copper electrode A to which positive ole of battery is connected, is called *anode*, while the electrode C connected to the egative pole is called *cathode*.

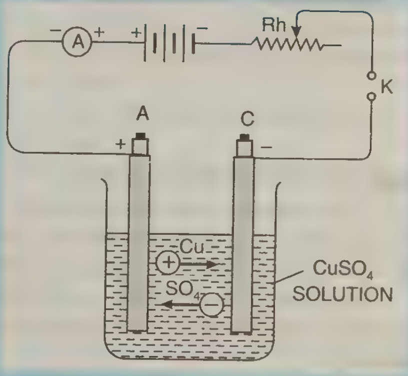

Fig. 4.01

When the circuit is switched on, current inside the voltameter is carried by the ons of the electrolyte and outside the voltameter, the current is carried by electrons. f the electrolyte is made acidic, the conductivity of the electrolyte improves without ffecting the reactions that take place inside the voltameter.

Mechanism of electrolysis. When the acidic copper sulphate solution issociates, the ions are produced as below :

$$\mathrm{CuSO_4} \longrightarrow \mathrm{Cu}^{++} + \mathrm{SO_4^{--}}$$
$$\mathrm{H_2O} \longrightarrow \mathrm{H}^+ + \mathrm{OH}^-$$

The Cu^{++} ions drift towards the cathode C. As soon as a Cu^{++} ion reaches the athode, two electrons from the negative pole of the battery flow into the cathode nd combine with the Cu^{++} ion to produce a neutral Cu atom. The Cu atom so roduced due to the discharge of Cu^{++} ion gets deposited at the cathode. The ollowing reaction takes place at the cathode :

$$\mathrm{Cu}^{++} + 2\,e^- \longrightarrow \mathrm{Cu}$$

As soon as a Cu^{++} ion discharges at the cathode, a Cu atom at the anode A eleases two electrons and the Cu^{++} ion so produced goes into the $\mathrm{CuSO_4}$ solution.

The two electrons so released flow from the anode to the positive pole of the battery. The following reaction takes place at the anode :

$$Cu \longrightarrow Cu^{++} + 2e^-$$

Therefore, the circuit completes due to the flow of ions inside the electrolyte and flow of electrons in the metallic connecting wires outside the voltameter. There is no accumulation of charge anywhere in the voltameter. The result of current flow in the circuit is simply the ***plating out of copper*** from the anode and its ***deposition*** at the cathode of the copper voltameter. However, the concentration of $CuSO_4$ solution remains the same during the process of electrolysis.

It may be noted that one Cu atom is deposited at the cathode for each pair of electrons flowing through the connecting wires. Therefore, the amount of copper deposited at the cathode during electrolysis is always directly proportional to the charge flowing through the circuit.

Key point

In an electric circuit containing a voltameter, current inside the voltameter i carried by ions and outside the voltamete current is carried by electrons.

4.06. ELECTROLYSIS OF WATER

A water voltameter consists of a glass vessel, at the base of which two platinum electrodes are provided. The vessel contains acidic water. Two long tubes filled with acidic water are held in inverted position over the two electrodes [Fig. 4.02]. A battery, a rheostat, an ammeter and a one-way key are connected to the two electrodes.

When current is passed through the acidic water, hydrogen gas is collected in the inverted tube put over cathode and oxygen gas is collected in the tube placed over anode.

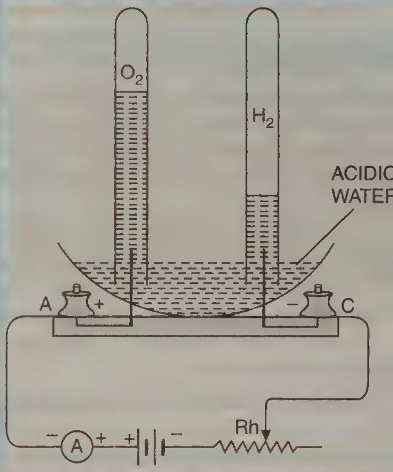

Fig. 4.02

Mechanism of electrolysis. The electrons from the negative terminal of the battery enter the cathode through the connecting wire and cause reduction of the water. The reaction at the cathode takes place as below :

$$4H_2O + 4e^- \longrightarrow 4OH^- + 2H_2$$

Due to this, hydrogen gas is liberated at the cathode. Also, the concentration of OH^- ions increases.

At the anode, concentration of OH^- ions is low. Due to dissociation of sulphuric acid (used to make water acidic), SO_4^{--} ions are also present at the anode but they are difficult to oxidize. As such, the main reaction at the anode is the direct oxidation of the water. The reaction takes place as below :

$$2H_2O \longrightarrow +4H^+ + 4e^- + O_2$$

The oxygen gas is liberated at the anode. Also, the released electrons reach the positive terminal of the battery after entering the anode and passing through the connecting wire. Further, due to this reaction, the concentration of H^+ ions increases. In the electrolyte, H^+ and OH^- move towards the cathode and anode respectively and neutralize according to following reaction :

$$4H^+ + 4OH^- \longrightarrow 4H_2O$$

If we add the respective sides of the above three reactions, we obtain

$$2H_2O \longrightarrow 2H_2 + O_2$$

4.07. FARADAY'S LAWS OF ELECTROLYSIS

The detailed experimental study of the electrolysis was carried out by Michael Faraday. The conclusions drawn by him are commonly known as ***Faraday's laws of electrolysis***. They are stated and discussed as below :

First law. *It states that the mass of substance deposited at the cathode during electrolysis is directly proportional to the quantity of electricity (total charge) passed through the electrolyte.*

Let m be the mass of the substance liberated, when a charge q is passed through the electrolyte. Then, according to Faraday's first law of electrolysis

$$m \propto q$$

or
$$m = z\,q, \qquad (4.01)$$

where the constant of proportionality z is called ***electrochemical equivalent* (E.C.E.) *of the substance***.

If a constant current I is passed through the electrolyte for time t, then the total charge passing through the electrolyte is given by

$$q = I\,t$$

Therefore, from equation (4.01), we have

$$m = z\,I\,t \qquad ...(4.02)$$

If $q = 1$ coulomb, then from equation (4.01), we have

$$m = z \times 1$$

or
$$z = m$$

Hence, *the electrochemical equivalent of substance may be defined as the mass of its substance deposited at the cathode, when one coulomb of charge passes through the electrolyte.*

The SI unit of electrochemical equivalent of a substance is **kilogram coulomb^{-1} (kg C^{-1})**. In practice, E.C.E. of a substance is expressed as **gram coulomb^{-1}** (g C^{-1}). The values of E.C.E. of a few common substances are given in the following table :

Element	Valency	Atomic weight	E.C.E. (g C^{-1})
Hydrogen	1	1 · 008	$104 \cdot 4 \times 10^{-7}$
Oxygen	2	16 · 000	829×10^{-7}
Chromium	3	52 · 010	1796×10^{-7}
Nickel	2	58 · 680	3040×10^{-7}
Copper	2	63 · 670	3294×10^{-7}
Zinc	2	65 · 380	3387×10^{-7}
Gold	3	197 · 200	6812×10^{-7}
Silver	1	107 · 880	11180×10^{-7}

Second law. *If same quantity of electricity is passed through different electrolytes, masses of the substances deposited at the respective cathodes are directly proportional to their chemical equivalents.*

The jargon .....

Chemical equivalent = $\dfrac{\text{atomic weight}}{\text{valency}}$

Let m be the mass of the ions of a substance liberated, whose chemical equivalent is E. Then, according to Faraday's second law of electrolysis,

$$m \propto \mathrm{E}$$

or
$$m = \text{constant} \times \mathrm{E}$$

or
$$\frac{m}{\mathrm{E}} = \text{constant} \qquad \text{...(4.03)}$$

Relation between chemical equivalent and electrochemical equivalent. Suppose that on passing same amount of electricity q through two different electrolytes, masses of the two substances liberated are m_1 and m_2. If E_1 and E_2 are their chemical equivalents, then from Faraday's second law, we have

$$\frac{m_1}{m_2} = \frac{\mathrm{E}_1}{\mathrm{E}_2} \qquad \text{...(4.04)}$$

Further, if z_1 and z_2 are the respective electrochemical equivalents of the two substances, then from Faraday's first law, we have

$$m_1 = z_1 q \qquad \text{and} \qquad m_2 = z_2 q$$

$$\therefore \qquad \frac{m_1}{m_2} = \frac{z_1}{z_2} \qquad \text{...(4.05)}$$

From equations (4.04) and (4.05), we have

$$\frac{z_1}{z_2} = \frac{\mathrm{E}_1}{\mathrm{E}_2}$$

or
$$z_2 = z_1 \times \frac{\mathrm{E}_2}{\mathrm{E}_1} \qquad \text{...(4.06)}$$

It gives the relation between chemical equivalents and electrochemical equivalents of two substances. Knowing z_1, E_1 and E_2, the above relation can be used to find electrochemical equivalent z_2 of an unknown substance. Further, from equation (4.06), it follows that

$$\frac{\mathrm{E}}{z} = \text{constant} \qquad \text{...(4.07)}$$

Note. The ratio E/z for a substance is known as *Faraday constant* and is equal to 96500 C mol^{-1}.

4.08. FARADAY CONSTANT

Faraday constant is the quantity of charge required to liberate one gram equivalent of the substance on an electrode during the process of electrolysis. It is denoted by F. It has a fixed value of 96500 C mol^{-1}.

Relation between Faraday constant and E.C.E. of a substance. Suppose that on passing electric charge q through an electrolyte, mass m of a substance is liberated.

If z is electrochemical equivalent of the substance, then from Faraday's first law, we have

$$m = z\,q$$

or
$$q = \frac{m}{z} \qquad \text{...(4.08)}$$

From definition of Faraday constant, it follows that when $m = \text{E}$ (chemical equivalent of the substance), $q = \text{F}$

Setting the above condition in equation (4.08), we have

$$\text{F} = \frac{\text{E}}{z} \qquad \text{...(4.09)}$$

Thus, *Faraday constant is equal to the ratio of chemical equivalent of a substance to its electrochemical equivalent.*

Key point

The ratio of chemical equivalent and electrochemical of a substance is known as ***Faraday constant***. Its value is same (96500 C mol^{-1}) irrespective of the nature of substance.

Further, equation (4.09) gives

$$z = \frac{\text{E}}{\text{F}} \qquad \text{...(4.10)}$$

Hence, *electrochemical equivalent of a substance is equal to the ratio of its chemical equivalent to Faraday constant.*

To express Faraday constant in terms of Avogadro number and electronic charge. Again, from Faraday's first law of electrolysis, we have

$$m = z\,q \qquad \text{...(4.11)}$$

Let us first calculate the quantity of charge required to liberate one mole of the substance. Suppose that the valency of the atoms of the substance is p. From the concept of the valency, it follows that in order to deposit one atom of the substance, p electrons have to pass through the electrolyte. In other words, when electric charge equal to pe is passed through the electrolyte, one atom of the substance will be deposited at the electrode. If N is Avogadro number, then

charge required to deposit one mole of the substance = N ($p\,e$)

Let M be mass of one mole of the substance. Then it follows that

when $q = \text{N}\,(p\,e), \quad m = \text{M}$

Setting the above condition in equation (4.11), we have

$$\text{M} = z\,\text{N}\,(p\,e)$$

or
$$\frac{\text{M}}{p} = z\,\text{N}\,e$$

But $\frac{\text{M}}{p} = \text{E}$, the chemical equivalent of the substance. Therefore, the above equation becomes

$$\text{E} = z\,\text{N}\,e$$

Substituting for E in equation (4.09), we have

$$\text{F} = \frac{z\,\text{N}\,e}{z}$$

or
$$\text{F} = \text{N}\,e \qquad \text{...(4.12)}$$

i.e. Faraday constant is equal to the product of Avogadro number and electronic charge.

Key point

Faraday constant is given by

$$\text{F} = \frac{\text{E}}{z} = \text{N}\,e,$$

where the letters have their usual meanings.

Since $\text{N} = 6{\cdot}0229 \times 10^{23}$ and $e = 1{\cdot}602 \times 10^{-19}$ C, we have

$$\text{F} = \text{N}\,e = 6{\cdot}0229 \times 10^{23} \times 1{\cdot}602 \times 10^{-19} = 96487 \text{ C} \approx 96500 \text{ C}$$

4.09. USES OF ELECTROLYSIS

The phenomenon of electrolysis has been put to many technical and commercial uses as detailed below :

1. Electroplating. The process of depositing a thin layer of a metal on any surface by electrolysis is called ***electroplating***. The article to be electroplated is made cathode and the metal to be deposited is made anode. A soluble salt of the metal (the metal to be deposited) is used as electrolyte. When the current is passed, a thin layer of the metal deposits on the material.

2. Extraction of metals from the ores. Certain metals are extracted from their ores by electrolysis. For example, aluminium is extracted by passing current through the fused ores bauxite (Al_2O_3) and cryolite ($Na_3\,AlF_6$).

3. Purification of metals. The impure metal is made anode and the pure metal is made cathode. The soluble salt of the pure metal is used as electrolyte. On passing current, pure metal gets deposited on the cathode. In this manner, copper has been purified upto 99·99%.

4. Electrotyping. Exact copies of the metallic type used in printing works and of the engraved blocks on metals can be prepared by the process of electrolysis. The impression of the type of block is first obtained on a soft material, such as wax. The mould (impression on wax) is made conducting by coating with graphite powder. Then, a thin film of copper is deposited by the process of electrolysis. This sheet gives a copy of the type or the engraved block.

5. Manufacture of caustic soda. By carrying out electrolysis of sodium chloride solution, caustic soda is prepared.

6. Electrolytic capacitors. An electrolytic capacitor consists of two aluminium electrodes dipping in a mixture of boric acid, glycerine and ammonia water. When current is passed, a thin film of aluminium oxide is formed on anode due to electrolysis, which acts as dielectric. As the thickness of the oxide layer is very small, the capacitor has a very large capacitance.

7. Noden valve. It is used to rectify an alternating e.m.f. up to 40 V and works on the phenomenon of electrolysis. It consists of two electrodes of lead and aluminium dipping in aqueous solution of an alkali borate. When an alternating e.m.f. is applied, the current flows only when aluminium electrode is negative. It, thus, acts as a rectifier.

8. Medical applications. Electrolysis is used for local ***anaesthesia*** (when current is passed through a nerve, it is rendered insensitive to pain) ; for ***nerve stimulation*** especially for polio ; for removing unwanted hair on any part of body, etc.

9. Chemical analysis. The process of electrolysis has been used for determining the composition of many chemical salts.

4.10. SOURCE OF E.M.F.

We know that water always flows from a place at higher level to the place at lower level and this movement of water due to difference in levels of the two places may be termed as water flow. Similarly, when two ends of a conductor are at different levels of electricity, electric charge flows from one end of the conductor to the other. This charge flow is called flow of electric current.

A conductor contains free electrons, which are always in random motion. The flow of free electrons in a definite direction constitutes the electric current through the conductor. It can be achieved by maintaining electric potential difference across the two ends of the conductor. The in electric potential difference across the two ends of the conductor performs the work in moving free electrons through the conductor in a definite direction. Such a device or an arrangement, which can maintain potential difference across a conductor is called ***source of e.m.f.***

Therefore, *a source of e.m.f. is an arrangement, which supplies energy in some form so as to bring about the movement of free electrons in a conductor in a particular direction.*

There are following types of sources of e.m.f. :

1. Electrochemical cell. *An electrochemical cell or simply a cell is an arrangement, in which chemical reaction takes place at a steady rate, so as to convert chemical energy into electrical energy.*

The total amount of electrical energy that can be provided by a cell is limited by the amount of reactants present in the cell.

The electrochemical cells are of two types namely ***primary cell*** and ***secondary cells***. The secondary cells are also known as ***storage cells.***

2. Photo cell. *A device in which light energy is converted into electrical energy is called a photo cell.*

Such a cell is based on the phenomenon ***of photoelectric effect***.

3. Thermocouple. A *thermocouple is a source of e.m.f., in which heat energy is converted into electrical energy.*

It is an arrangement of two wires of different materials joined at their ends, so as to form two junctions. When one junction is kept hot and the other cold, electric current flows through the arrangement. It is called ***Seebeck effect*** or ***thermoelectric effect.***

4. Electrostatic machines. By making use of some electrostatic phenomena, machines have been developed which may be used to provide very high voltages. For example, electrophorus, Wimshurst machine, Van de Graaff generator, etc.

5. Electric generator. *It is a device in which mechanical energy required to rotate a conducting loop in a magnetic field is converted into electrical energy.*

An electric generator is based on the phenomenon of ***electromagnetic induction.***

6. Other cells. (*i*) Certain radioactive substances (β-emitters) emit electrons over long periods. Such radioactive substances are used in constructing ***atomic cells.***

(*ii*) When a mechanical stress is applied in a suitable direction on certain crystals, such as tourmaline, quartz and Rochelle salt, the opposite faces become electrically charged. In other words, in such crystals, mechanical energy gets transformed into electrical energy. Such crystals are called ***piezo crystals.*** The transformation of mechanical energy into electrical energy in such crystals is known as ***piezo electric effect*** and such a mechanism constitutes a ***piezo electric cell*** or ***piezo electric generator.***

4.11. PRIMARY AND SECONDARY CELLS

Primary cell. *It is an electrochemical cell, which once discharged, cannot be put to use again by passing electric current from an external source.*

Therefore, when a primary cell gets discharged, the chemicals inside the cell have to be replaced completely. Daniel cell, Leclanche cell and Bunsen cell are examples of primary cells.

Secondary cell. *It is an electrochemical cell, which has to be charged initially by passing electric current from an external source, so as to convert the stored chemical energy into electrical energy.*

On getting discharged, a secondary cell can again be put into use by recharging it. In other words, the chemical reactions that take place inside a secondary cell are reversible in nature. Since a secondary cell stores energy when it is charged, it is also called a ***storage cell*** or an ***accumulator.*** Lead acid cell and alkali cells are two commonly used secondary cells.

Advantages of a secondary cell over a primary cell. 1. A secondary cell can be put to use again and again by recharging it ; while a primary cell once discharged, cannot be recharged.

2. The internal resistance of a secondary cell is less than that of a primary cell. As such, a secondary cell enables to draw much larger current.

Disadvantages of a secondary cell. 1. A secondary cell has to be charged first, so as to obtain electrical energy from it. In other words, a secondary cell requires a lot of time before it can be put to use, while a primary cell starts functioning immediately after its construction.

2. The initial cost of a secondary cell is quite large as compared to that of a primary cell.

4.12. PRIMARY CELLS

Luigi Galvani, an Italian professor of anatomy accidentally made a discovery, which led to the development of first primary cell. He observed that when the two ends of the exposed nerves in the leg of a freshly dissected frog were connected through a copper and iron wire, the leg jerked violently. He concluded that the effect was due to animal electricity in the frog's leg.

Alessandro Volta investigated the accidental discovery of animal electricity made by Galvani. He concluded that two dissimilar metals (copper and iron wires) immersed in a conducting fluid (fluid in frog's leg) led to a chemical reaction capable of producing an electric current, which caused the frog's leg to jerk violently. Ultimately, Volta invented the first primary cell, now called the ***simple voltaic cell.***

This cell suffered from a few defects. In order to remove them, other cells were developed. In addition to simple voltaic cell ; Daniel cell, Bunsen cell and Leclanche cell are the other primary cells.

4.13. SIMPLE VOLTAIC CELL

It was invented by Allexandro de Volta in the year 1800.

Construction. It consists of a glass vessel containing dilute sulphuric acid as electrolyte. Two rods, one of copper and the other made of zinc, are placed in dilute sulphuric acid as shown in Fig. 4.03. Due to the chemical reactions inside the cell, the zinc rod acquires negative charge and the copper rod positive charge. As a result, a potential difference is established between the copper and the zinc rods. The copper rod is called *positive pole,* while the zinc rod is called *negative pole* or *terminal* of the cell.

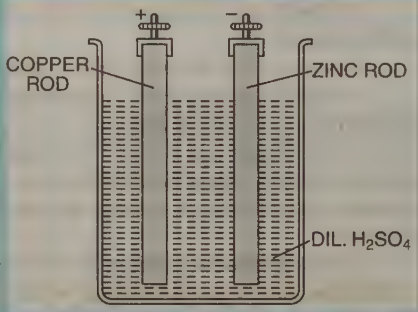

Fig. 4.03

Action. The dilute sulphuric acid dissociates into positive hydrogen ions (H^{++}) and negative sulphate ions (SO_4^{--}) as represented below :

$$H_2SO_4 \longrightarrow 2H^+ + SO_4^{--}$$

When the copper and zinc rods are placed in dilute sulphuric acid, some of the neutral zinc atoms go into the electrolyte as Zn^{++} ions as represented below :

$$Zn \longrightarrow Zn^{++} + 2e^-$$

For each Zn^{++} ion so produced, two electrons ($2e^-$) are left on the zinc rod. As more and more Zn^{++} ions enter the electrolyte, the zinc rod becomes more and more negative. Also, the concentration of Zn^{++}ions in the electrolyte goes on increasing. The H^+ ions drift to the copper rod. On reaching the copper rod, the H^+ ions extract electrons from the rod and form neutral hydrogen atoms. As a result of it, copper rod acquires positive charge. As more and more H^+ ions discharge at the copper rod, it becomes more and more positive. Due to positive charges building up on copper rod and negative charge on the zinc rod, the potential difference between the two rods goes on increasing. It continues, till the potential gradient along the electrolyte between copper and zinc rod just restricts the drift of H^+ ions to the copper rod. The maximum e.m.f. developed in voltaic cell is found to be 1·08 V.

Defects in a voltaic cell. A voltaic cell suffers from the following two defects :

1. ***Local action.*** The commercial zinc usually contains traces of iron and lead. When zinc rod containing such impurity atoms of iron and lead is dipped in dilute sulphuric acid, tiny voltaic cells are formed locally on the zinc rod and in these cells, local electric currents are set up. Due to these local currents, zinc is converted into $ZnSO_4$ and hence wasted even when the cell is not in use. This defect in voltaic cell is called ***local action***.

Key point ✓

A simple voltaic cell suffers from the defects of local action and polarisation.

To remove this defect, the zinc rod is rubbed with mercury. The impurity atoms of iron and lead are insoluble in mercury and hence they get covered with a layer of mercury. On the other hand, zinc forms a mercury amalgam. Due to this, whereas the impurity atoms of iron and lead are no longer exposed to dilute sulphuric acid, the zinc atoms remain exposed. Thus, on amalgamating the zinc rod, the chemical action inside the cell is sustained without any local action.

Key point ✓

The defect of local action arises in a simple voltaic cell due to formation of tiny voltaic cells on the zinc rod.Such cells are formed due to the reason that commercial zinc contains traces of iron and lead.

2. ***Polarisation.*** This defect arises due to the formation of a neutral layer of hydrogen gas on copper rod, when the H^+ ions on reaching copper rod extract electrons from it and form hydrogen atoms. The layer of hydrogen gas on the copper rod weakens the action of the cell in the following two ways :

(i) The layer of hydrogen is a bad conductor of electricity. Due to this, internal resistance of the cell increases.

(ii) Due to the formation of a layer of hydrogen gas, H^+ ions moving towards the copper rod are unable to transfer their positive charge on it. As such, H^+ ions set up an electric field from the layer of hydrogen to zinc rod and oppose the motion of H^+ ions towards the copper rod. It results in ***back electromotive force***, which sends the current in opposite direction and weakens the action of the cell. This defect in the cell is called ***polarisation***. This defect can be removed by brushing off the hydrogen from time to time or by using a depolariser (an oxidising agent), which will convert hydrogen gas into water.

Key point ✓

The defect of polarisation arises in a voltaic cell due to deposition of a layer of hydrogen on copper rod, which is bad conductor of electricity.

4.14. DANIEL CELL

It was developed by Daniel in the year 1836.

Construction. It consists of a copper vessel containing copper sulphate ($CuSO_4$) solution. The copper vessel itself acts as the positive pole of the cell. Inside the $CuSO_4$ solution, a porus pot containing an amalgamated zinc rod and dilute H_2SO_4 acid is placed as shown in Fig. 4.04. Whereas the porus pot prevents the dilute H_2SO_4 and the $CuSO_4$ solution from mixing with each other, it allows the H^+ ions produced in the porus pot to diffuse through its walls into the $CuSO_4$ solution. The amalgamated zinc rod is used in order to avoid the defect of local action from occurring in the cell. The amalgamated zinc rod acts as the negative pole of the cell and both the $CuSO_4$ solution and dil. H_2SO_4 serve as the electrolyte. However, the $CuSO_4$ solution serves as depolariser also.

When the cell functions, the concentration of $CuSO_4$ solution falls. In order to keep the concentration of $CuSO_4$ solution constant, the crystals of $CuSO_4$ are placed on the perforated shelf provided along the walls of the copper vessel.

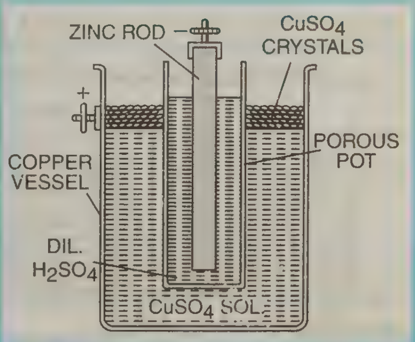

Fig. 4.04.

Action. Inside the porus pot, the dilute H_2SO_4 acid dissociates into H^+ and SO_4^{--} ions. As the zinc rod is dipping inside the dilute H_2SO_4 acid, some of the zinc atoms go into the solution as Zn^{++} ions. For each Zn^{++} ion going into the solution, two electrons are left on the zinc rod. As the concentration of Zn^{++} ions in the solution increases, zinc rod becomes more and more negative and the H^+ ions diffuse through the walls of the porus pot into the $CuSO_4$ solution. The reactions taking place inside the porus pot are as below :

$$H_2SO_4 \longrightarrow 2\,H^+ + SO_4^{--}$$
$$Zn \longrightarrow Zn^{++} + 2\,e^-$$
$$Zn^{++} + SO_4^{--} \longrightarrow ZnSO_4$$
$$\overline{\underline{Zn + H_2SO_4 \longrightarrow ZnSO_4 + 2\,H^+ + 2\,e^-}}$$

The formation of $ZnSO_4$ on the porus pot does not affect the working of the cell, until crystals of $ZnSO_4$ are deposited along its walls.

On diffusing out of porus pot, H^+ ions react with copper sulphate solution as below :

$$2\,H^+ + CuSO_4 \longrightarrow H_2SO_4 + Cu^{++}$$

As the Cu^{++} ions deposit on the copper vessel, it acquires positive charge. Due to building up of the positive charge on the copper vessel and negative charge on the zinc rod, the potential difference between the two poles of the cell goes on increasing. When equilibrium is attained, the cell developes an e.m.f. of 1·1 V.

It may be pointed out that the use of $CuSO_4$ solution makes Cu^{++} ions to discharge at the copper vessel in place of H^+ ions. In case, H^+ ions discharged at the copper vessel, the defect of polarisation would occur due to the production of H_2 gas. Therefore, due to the use of $CuSO_4$ solution, the defect of polarisation is avoided in Daniel cell. The $CuSO_4$ solution is said to be acting as ***depolariser***. However, as the cell works, the concentration of $CuSO_4$ solution falls and this in turn decreases the e.m.f. of the cell. But before this may happen, some $CuSO_4$ crystal from the perforated shelf get dissolved into $CuSO_4$ solution and the concentration of $CuSO_4$ solution recovers to the original value. As the concentration of $CuSO_4$ solution is maintained, the cell provides the steady e.m.f., while in use.

Key point

In a Daniel cell, the defect of polarisation is avoided by using $CuSo_4$ solution as depolariser.

4.15. LECLANCHE CELL

It was invented by George Leclanche in the year 1865.

Construction. It consists of a glass vessel containing a strong solution of ammonium chloride (NH_4Cl) as electrolyte. An amalgamated zinc rod dipping in the NH_4Cl solution acts as the negative pole of the cell. The use of amalgamated zinc rod avoids the defect of local action from occurring in the cell. A porus pot containing the carbon rod is placed inside the NH_4Cl solution. The carbon rod acts as the positive pole of the cell. The empty space in the porus pot is filled with manganese dioxide (MnO_2) and charcoal powder [Fig. 4.05]. Manganese dioxide is used as *depolariser*. The use of charcoal powder makes MnO_2 conducting and thus, decreases the internal resistance of the cell.

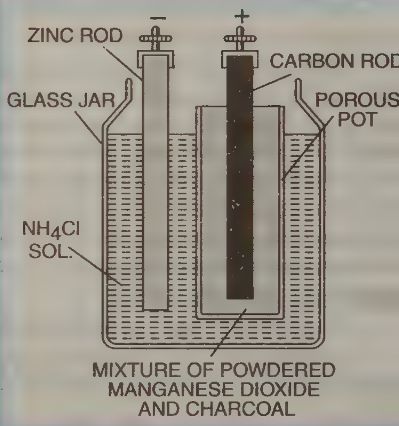

Fig. 4.05

Action. The electrolyte NH_4Cl solution dissociates into NH_4^+ and Cl^- ions. As zinc rod is dipping inside the NH_4Cl solution, some of the atoms go into the solution as Zn^{++} ions. For each Zn^{++} ion so produced, two electrons are left on the zinc rod and hence it becomes negative pole of the cell. The NH_4^+ ions are repelled by Zn^{++} ions and they diffuse into the MnO_2 and charcoal mixture through the walls of the porus pot. Inside the glass vessel, Zn^{++} ions combine with Cl^- ions to form $ZnCl_2$. The reactions taking place inside the glass vessel are as below :

$$2\,NH_4Cl \longrightarrow 2\,NH_4^+ + 2\,Cl^-$$
$$Zn \longrightarrow Zn^{++} + 2\,e^-$$
$$Zn^{++} + 2\,Cl^- \longrightarrow ZnCl_2$$
$$\overline{\underline{Zn + 2\,HN_4Cl \longrightarrow ZnCl_2 + 2\,NH_4^+ + 2\,e^-}}$$

On diffusing into porus pot, NH_4^+ ions extract electrons from the carbon rod making carbon rod as positively charged and producing ammonia and hydrogen gas as represented below :

$$2\,NH_4^+ + 2\,e^- \longrightarrow 2\,NH_3 + H_2$$

Whereas the ammonia gas escapes from the cell, hydrogen gas is neutralised by MnO_2 producing manganese trioxide (Mn_2O_3) and water as below :

$$2\,MnO_2 + H_2 \longrightarrow Mn_2O_3 + H_2O$$

It may be pointed out that by converting hydrogen gas into water, MnO_2 prevents hydrogen gas from causing the defect of polarisation in the cell. Therefore, MnO_2 acts as depolariser in Leclanche cell. The e.m.f. of Leclanche cell is nearly 1·5 V.

However, the defect of polarisation is found to occur, if the cell is used continuously. Being a solid depolariser, MnO_2 reacts with the hydrogen gas at a much slower rate, than at which it is liberated. Therefore, after some time, there is partial polarisation due to accumulation of hydrogen gas and the e.m.f. of the cell falls.

It is found that if the cell is allowed to rest for some time by switching off the circuit, the e.m.f. of the cell recovers. It is because, during this period, Mn_2O_3 changes back into MnO_2 by taking oxygen from the atmosphere as represented below :

$$2\,Mn_2O_3 + O_2 \longrightarrow 4\,MnO_2$$

Because of this reason, Leclanche cell is used in experiments, where only intermittent supply of electric current is required.

Key point ✓

In a Leclanche cell, the defect of polarisation is avoided by using MnO_2 as depolariser. Being a solid, MnO_2 reacts with hydrogen gas at a much slower rate. Therefore, if the cell is used continuosly, there is partial polarisation due to accumulation of hydrogen gas. The cell is found to recover, if rested for a small time. For this reason, Leclanche cell is used for obtaining current for intermittent intervals.

4.16. DRY CELL

It is a portable form of a Leclanche cell.

Construction. In a dry cell, a moist paste of ammonium chloride containing zinc chloride is used as an electrolyte. Zinc chloride being highly hydroscopic, it is added to ammonium chloride in order to keep it moistened. The paste of NH_4Cl and $ZnCl_2$ is contained in a small cylindrical zinc vessel, which acts as the negative pole of the cell. A carbon rod fitted with a brass cap is placed in the middle of the zinc vessel. It acts as the positive pole of the cell. The carbon rod is surrounded by a closely packed mixture of MnO_2 and charcoal powder in a muslin bag. While the MnO_2 acts as depolariser, the charcoal powder reduces the internal resistance of the cell by making MnO_2 electrically conducting. The zinc container and its contents are sealed at the top with pitch or shellac as shown in Fig. 4.06. A small hole is provided at the top, so as to allow ammonia gas formed during chemical reactions to escape the cell.

Action. A dry cell is only a modification of a wet Leclanche cell. Therefore, the action of a dry cell as regards the chemical reactions that take place are same as in case of Leclanche cell.

The dry cells are manufactured in different sizes and shapes to suit particular needs. Irrespective of the size of the cell, the e.m.f. of the cell is nearly 1·5 V. Its internal resistance may vary from $0{\cdot}1\ \Omega$ to$10\ \Omega$. Further, an electric current of about 0·25 A can be continuously drawn from a dry cell.

Key point ✓

A dry cell is portable form of Lenclanche cell.

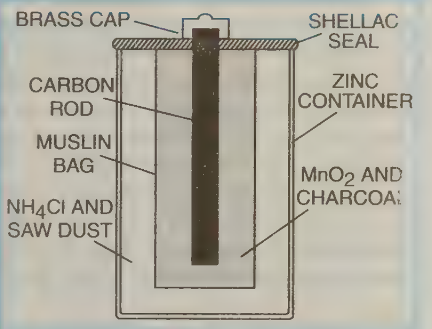

Fig. 4.06

4.17. SECONDARY CELLS

A secondary cell is one in which chemical energy is converted into electrical energy but they do so only when they are charged by passing current through them by some source.

These are also called accumulators or storage cells. These are of two types :

1. Lead acid cell or lead accumulator **2.** Edison alkali cell

4.18. LEAD ACCUMULATOR

It is a secondary cell and is the most common type of storage battery used in automobiles. It is also known as lead acid cell. It was invented by French Physicist, Gaston Plante in the year 1859.

Construction. It consists of a hard rubber, glass or celluloid container containing dilute sulphuric acid as the electrolyte. Each of the two electrodes consists of a set of alternate parallel mesh type perforated plates made of lead. The set of plates to be made the positive pole is filled with a paste of lead dioxide (PbO_2), while the set of plates to be made the negative pole is filled with a paste of spongy lead (Pb). The positive and negative plates are kept separated and insulated from each other by porus separators made of rubber, plastic or glass fibre. This arrangement of positive and negative plates is placed inside the dilute sulphuric acid and connected to the lead terminals provided on the hard and rigid cover of the container [Fig. 4.07].

The e.m.f. of each cell of a fully charged lead accumulator is 2·05 V and a lead accumulator of such six cells produces an e.m.f. of nearly 12 V. The specific gravity of the electrolyte (dilute sulphuric acid) in a fully charged lead accumulator is 1·28.

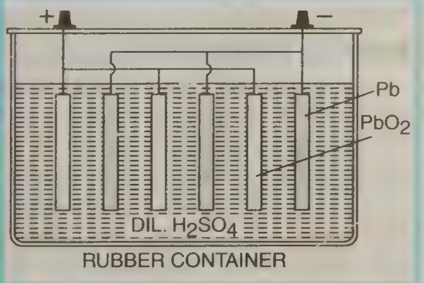

Fig. 4.07

However, when discharged, both the e.m.f. of the cell and the specific gravity of the electroyte fall. Whereas, e.m.f. of a cell of the accumulator should not be allowed to fall below 1·8V, the specific gravity of the electrolyte should not drop below 1·12.

Discharging. When the cell is connected to an external load circuit, it sends current in the circuit and starts discharging. The dilute sulphuric acid dissociates into H^+ and SO_4^{--} ions as below :

$$H_2SO_4 \longrightarrow 2H^+ + SO_4^{--}$$

The H^+ ions drift towards the positive plate, while SO_4^{--} ions move towards the negative plate of the accumulator. The chemical reactions take place at the two plates of the accumulators as given below :

At the negative plate :

$$Pb + SO_4^{--} - 2e^- \longrightarrow PbSO_4$$

At the positive plate :

$$\begin{array}{r}PbO_2 + 2H^+ + 2e^- \longrightarrow PbO + H_2O\\ PbO + H_2SO_4 \longrightarrow PbSO_4 + H_2O\\ \hline PbO_2 + H_2SO_4 + 2H^+ + 2e^- \longrightarrow PbSO_4 + 2H_2O\\ \hline\end{array}$$

Therefore, during discharging, the materials of each plate is converted into $PbSO_4$. The lead sulphate produced in these reactions is a soft form and is chemically more active than the hard lead sulphate. Further, H_2SO_4 molecules do not exist in the solution as such. As said above, it dissociates into H^+ and SO_4^{--}. Therefore, the reaction at positive plate may be written as below :

$$PbO_2 + 4H^+ + SO_4^{--} + 2e^- \longrightarrow PbSO_4 + 2H_2O$$

Further, in the discharging reactions, sulphuric acid is consumed and water is formed. As a result, the specific gravity of the sulphuric acid falls.

Charging. In order to charge a lead accumulator, it is connected to a battery charger capable of supplying e.m.f. greater than that of the lead accumulator. While charging an accumulator, a high series resistance is included in the circuit. In the absence of such a resistance, large current flows through the accumulator during charging. Due to this, a non-porus layer of $PbSO_4$ is formed on both the plates, which does not decompose during subsequent charging. Further, the positive plate of the accumulator has to be connected to the positive terminal of the battery charger *i.e.* the battery charger has to force the charging current through the accumulator in the direction opposite to that of the discharging current. It will, then, make H^+ions to move towards negative plate and SO_4^{--} ions towards the positive plate. The following chemical reactions take place at the two plates :

Key point

During charging of a storage cell, curren from the battery charger flows into th cell. As a result, the terminal potentia difference between the two terminals of storage cell during charging is more tha its e.m.f. It is because, potential dro across internal resistance of the cell aid its e.m.f.

At the negative plate :

$$PbSO_4 + 2H^+ + 2e^- \longrightarrow Pb + H_2SO_4$$

At the positive plate :

$$\begin{array}{r}PbSO_4 + SO_4^{--} - 2e^- \longrightarrow PbO_2 + 2SO_3\\ 2SO_3 + 2H_2O \longrightarrow 2H_2SO_4\\ \hline PbSO_4 + 2H_2O + SO_4^{--} - 2e^- \longrightarrow PbO_2 + 2H_2SO_4\end{array}$$

Therefore, during the charging process, $PbSO_4$ at both electrodes is converted back into spongy lead (Pb) at negative plate and PbO_2 at positive plate. Further, in the charging reactions, water is consumed and sulphuric acid is produced. As a result, the specific gravity of the sulphuric acid rises.

Key point

While charging a storage cell, a larg resistance is put in series with the storag cell. In case, it is not done so, a larg current flows through the storage cell. I is rendered useless due to the formation o a non-porus layer of $PbSO_4$ on the plate of the accumulator.

4.19. EDISON ALKALI CELL

It is also called nickel-iron (Ni-Fe) cell. Its positive plate consists of a number of tubes of perforated steel ribbon, wound spirally and held together by steel rings. The tubes are nickel plated. The active material consisting of $Ni(OH)_4$ and flakes of metallic nickel are packed into the nickel plated steel tubes in alternate layers.

The negative plate is made from finely perforated nickelled steel strip, stamped into pockets. The pockets are filled with powdered iron oxide.

The plates are separated from one another by hard rubber strips. The chemical changes during charging and discharging can be represented by the following reversible reaction :

$$Ni(OH)_4 + KOH + Fe \rightleftharpoons Ni(OH)_2 + KOH + Fe(OH)_2$$

The e.m.f. of the fully charged cell is 1·45 volt and it falls to 1·2 volt on discharge.

This cell is light portable and does not need special care. It is more durable and robust. Its internal resistance is greater than the lead accumulator and its efficiency is low.

4.20. CAPACITY OF A SOURCE OF E.M.F.

The capacity of source of e.m.f., such as an accumulator, is measured in *ampere hour.*

The capacity of a source of e.m.f. is called one ampere hour, if it can discharge one ampere of current for one hour.

For example, a lead accumulator having capacity of 80 ampere hour can supply 8 ampere of current for 10 hours or 4 ampere current for 20 hours.

4.21. BUTTON CELL

The button cells are usually *pallet type flat* in construction and look like a button in shape. Owing to their small sizes, they are used in small electronic devices so as to minimise space and weight. Different types of button cells have been developed which make use of positive and negative electrodes of different nature. However, all types of button cells are basically primary cells.

Fig. 4.08 shows the various parts of a ***zinc-air button cell***. In this cell, zinc (in powder form) acts as the negative electrode, while air as the positive electrode. It contains potassium hydroxide as the electrolyte. The whole arrangement is made inside a small metal can having a small hole at its bottom. A layer of polytetrafluroethane (abbreviated as PTFE) allows air into the cell through the hole but prevents the electrolyte from leaking out. PTFE is a chemically inert solid plastic and is known by the trade names teflon and fluon. It is heat resistant and is stable upto 300°C. Under the catalytic action of carbon, the oxygen from the air reacts with potassium hydroxide to form water.

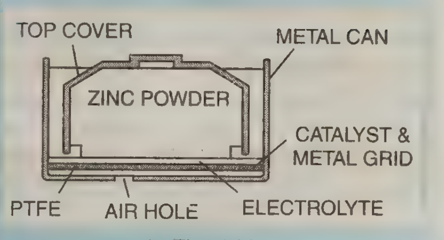

Fig. 4.08

A zinc-air botton cell provides an e.m.f. of 1·4 V. It is used in electronic devices, such as watches, pocket calculators, hearing aid, etc. A few other types of button cells are as listed below :

1. Nickel-cadmium button cell
2. Lithium-manganese button cell
3. Silver-zinc button cell
4. Alkaline manganese button cell
5. Silver oxide button cell
6. Mercury oxide button cell

SOLVED NUMERICAL PROBLEMS

Type A. On Faraday's first law of electrolysis

Problem 4.01. For what time must a constant current of 2 A pass through a copper voltameter to deposit 1 g of copper on the cathode ? Given that the E.C.E. of copper = 3·3 ×10⁻⁷ kg C⁻¹. *(H.S.S.C.E. 2002)*

Sol. Here, $m = 1\text{ g} = 10^{-3}\text{ kg}$; $I = 2\text{ A}$;

$z = 3{\cdot}3 \times 10^{-7}\text{ kg C}^{-1}$

From Faraday's first law of electrolysis,

$$m = zIt$$

$$\therefore \quad t = \frac{m}{zI} = \frac{10^{-3}}{3{\cdot}3 \times 10^{-7} \times 2} = 1515{\cdot}2\text{ s}$$

Problem 4.02. A steady current deposits 0·15 g of copper in 15 minutes from $CuSO_4$ solution. An ammeter in series with the voltameter reads 0·6 A. What correction is to be applied to the ammeter reading ? Given that E.C.E. of copper = 3·3 × 10⁻⁷ kg C⁻¹.

Sol. Here, $m = 0{\cdot}15\text{ g} = 0{\cdot}15 \times 10^{-3}\text{ kg}$;

$z = 3{\cdot}3 \times 10^{-7}\text{ kg C}^{-1}$

$t = 15\text{ minutes} = 15 \times 60 = 900\text{ s}$

Let I be the current passed through $CuSO_4$ solution. Then

$$I = \frac{m}{zt} = \frac{0{\cdot}15 \times 10^{-3}}{3{\cdot}3 \times 10^{-7} \times 900} = 0{\cdot}5\text{ A}$$

The value of current noted from ammeter, $I' = 0{\cdot}6$ A

Therefore, correction to be applied to the ammeter reading,

$$I - I' = 0{\cdot}5 - 0{\cdot}6 = -\,0{\cdot}1\text{ A}$$

Problem 4.03. A brass rectangular plate 12 cm × 3 cm is to be electroplated with copper. If we wish to coat it with a layer 0·02 mm thick on both sides, how much time will it take with a constant current of 5 A ? Given E.C.E. for copper is 33 × 10⁻⁵ g C⁻¹ and density of copper is 8·9 g cm⁻³.

Sol. Total area of the plate to be coated

$= 2 \times (12 \times 3)\text{ cm}^2 = 72\text{ cm}^2$

Thickness of copper layer to be coated

$= 0{\cdot}02\text{ mm} = 0{\cdot}002\text{ cm}$

Therefore, volume of the copper to be deposited

$= 72 \times 0{\cdot}002 = 0{\cdot}144\text{ cm}^3$

Mass of the copper to be deposited,

$m = \text{volume} \times \text{density}$

$= 0{\cdot}144\text{ cm}^3 \times 8{\cdot}9\text{ g cm}^{-3} = 1{\cdot}2816\text{ g}$

Let t be the time taken to deposit the copper. Then,

$$m = zIt$$

Here, $z = 33 \times 10^{-5}\text{ g C}^{-1}$; $I = 5$ A

$$\therefore \quad t = \frac{m}{zI} = \frac{1{\cdot}2816}{33 \times 10^{-5} \times 5} = 777\text{ s}$$

Problem 4.04. A silver and a copper voltameter are connected in parallel across a 6 V battery of negligible internal resistance. In half hour, 1 g of copper and 2 g of silver are deposited. Calculate the rate at which the energy is supplied by the battery. Given, the E.C.E. of copper is 3294×10^{-7} g C^{-1} and that of silver is 1118×10^{-6} g C^{-1}.

Sol. Let z_1 and z_2 be the E.C.E. of silver and copper respectively and m_1 and m_2 be the masses of the silver and copper deposited. If I_1 and I_2 be the currents through the silver and copper voltameters, then

$$m_1 = z_1 I_1 t \qquad ...(i)$$

and $$m_2 = z_2 I_2 t, \qquad ...(ii)$$

where t is the time for which current flows through each electrolyte.

Here, $m_1 = 2$ g ; $m_2 = 1$ g ; $t = \frac{1}{2}$ hour $= 1800$ s

$z_1 = 1118 \times 10^{-6}$ g C^{-1} ; $z_2 = 3294 \times 10^{-7}$ g C^{-1}

Therefore, from equations (*i*) and (*ii*), we have

$$I_1 = \frac{m_1}{z_1 t} = \frac{2}{1118 \times 10^{-6} \times 1800} = 0{\cdot}994 \text{ A}$$

Also, from equation (*ii*), we have

$$I_2 = \frac{m_2}{z_2 t} = \frac{1}{3294 \times 10^{-7} \times 1800} = 1{\cdot}687 \text{ A}$$

Total current drawn from the battery,

$$I = I_1 + I_2 = 0{\cdot}994 + 1{\cdot}687 = 2{\cdot}681 \text{ A}$$

Power of the circuit,

P = current × e.m.f. = 2·681 × 6 = **16·086 watt**

Problem 4.05. A silver and copper voltameter are connected in series with a 12 V battery of negligible resistance. It is found that 0·403 g of silver is deposited in 15 minutes. Find (*a*) the mass of the copper deposited and (*b*) the energy supplied by battery. Given that

E.C.E. of silver = $1{\cdot}12 \times 10^{-6}$ kg C^{-1} and

that of copper = $3{\cdot}3 \times 10^{-7}$ kg C^{-1}.

Ans. Here, mass of silver deposited,

$$m_1 = 0{\cdot}403 \text{ g} = 0{\cdot}403 \times 10^{-3} \text{ kg}$$

E.C.E. of silver, $z_1 = 1{\cdot}12 \times 10^{-6}$ kg C^{-1};

E.C.E. of copper, $z_2 = 3{\cdot}3 \times 10^{-7}$ kg C^{-1}

Time for which current is passed,

t = 15 minutes = 15 × 60 = 900 s

E.M.F. of battery, E = 12 V

(*a*) Since the two voltameters are in series, the same current passes through each of them. If I is current through the two voltameters, then

$$m_1 = z_1 I t \text{ and } m_2 = z_2 I t$$

$$\therefore \quad \frac{m_1}{m_2} = \frac{z_1}{z_2}$$

or $$m_2 = m_1 \times \frac{z_2}{z_1} = \frac{0{\cdot}403 \times 10^{-3} \times 3{\cdot}3 \times 10^{-7}}{1{\cdot}12 \times 10^{-6}}$$

$$= \mathbf{0{\cdot}119 \times 10^{-3} \text{ kg}}$$

(*b*) The energy supplied by the battery = E I t

$$= E\left(\frac{m_1}{z_1 t}\right)t \qquad (\because m_1 = z_1 I t)$$

$$= \frac{12 \times 0{\cdot}403 \times 10^{-3}}{1{\cdot}12 \times 10^{-6}} = \mathbf{4{\cdot}32 \times 10^3 \text{ J}}$$

Problem 4.06. A copper voltameter is connected in series with a coil of resistance 100 ohm. A steady current is passed through the circuit for 10 minutes and deposits 0·1 g of copper. How many joule of heat generated in the coil ? Take electrochemical equivalent copper $3{\cdot}3 \times 10^{-7}$ kg C^{-1}. (*C.B.S.E. 19*

Sol. Here, R = 100 ohm ;

t = 10 minutes = 60 × 10 = 600 s ;

$z = 3{\cdot}3 \times 10^{-7}$ kg C^{-1} ; $m = 0{\cdot}1$ g $= 10^{-4}$ kg

Now, $$m = z I t$$

or $$I = \frac{m}{zt} = \frac{10^{-4}}{3{\cdot}3 \times 10^{-7} \times 600} = 0{\cdot}505 \text{ A}$$

Heat produced in the resistance coil,

$$Q = I^2 R t = (0{\cdot}505)^2 \times 100 \times 600 = \mathbf{15301{\cdot}5}$$

Type B. On Faraday's second law of electrolysis

Problem 4.07. The mass of hydrogen (H_2) evolved p unit coulomb of electricity passed through a wa voltameter is $1{\cdot}05 \times 10^{-8}$ kg C^{-1}. The corresponding figu for copper deposited in a copper voltameter and sil deposited in a silver voltameter are $3{\cdot}29 \times 10^{-7}$ kg C^{-1} a $1{\cdot}12 \times 10^{-6}$ kg C^{-1} respectively. What conclusion is impl by these measure-ments ? Predict the amount of ir deposited per coulomb in a voltameter with Fe electro in $FeCl_3$. Relative atomic masses of hydrogen, copper, sil and iron are1·008, 63·54, 107·9 and 55·85 respectively.

(*Text Probl*

Sol. *For water voltameter* :

Atomic mass of hydrogen = 1·008 ; valency = 1

Therefore, chemical equivalent,

$$E_1 = \frac{1{\cdot}008}{1} = 1{\cdot}008 \text{ g mole}^{-1}$$

Also, mass of hydrogen liberated,

$$m_1 = 1{\cdot}05 \times 10^{-8} \text{ kg } C^{-1}$$

$$\therefore \quad \frac{m_1}{E_1} = \frac{1{\cdot}05 \times 10^{-8}}{1{\cdot}008} = 1{\cdot}0417 \times 10^{-8}$$

For copper voltameter :

Atomic mass of copper = 63·54 ; valency = 2

Therefore, chemical equivalent,

$$E_2 = \frac{63{\cdot}54}{2} = 31{\cdot}77 \text{ g mole}^{-1}$$

Also, mass of copper deposited,

$$m_2 = 3{\cdot}29 \times 10^{-7} \text{ kg } C^{-1}$$

$$\therefore \quad \frac{m_2}{E_2} = \frac{3{\cdot}29 \times 10^{-7}}{31{\cdot}77} = 1{\cdot}0356 \times 10^{-8}$$

For silver voltameter :

Atomic mass of silver =107·9 ; valency = 1

Therefore, chemical equivalent,

$$E_3 = \frac{107{\cdot}9}{9} = 107{\cdot}9 \text{ g mole}^{-1}$$

Also, mass of silver deposited, $m_3 = 1{\cdot}12 \times 10^{-6}$ kg

$$\therefore \quad \frac{m_3}{E_3} = \frac{1{\cdot}12 \times 10^{-6}}{107{\cdot}9} = 1{\cdot}0380 \times 10^{-8}$$

It follows that $\dfrac{m_1}{E_1} \approx \dfrac{m_2}{E_2} \approx \dfrac{m_3}{E_3}$

or $$\frac{m}{E} = \text{constant}$$

Therefore, these measurements lead to the verificat of Faraday's second law of electrolysis.

For iron voltameter :

Atomic mass of iron = 55·85 ; valency = 3

Therefore,chemical equivalent,

$$E_4 = \frac{55{\cdot}85}{3} = 18{\cdot}617 \text{ g mole}^{-1}$$

If m_4 is mass of iron deposited, then

$$\frac{m_1}{E_1} = \frac{m_4}{E_4}$$

or $$m_4 = \frac{m_1}{E_1} \times E_4 = 1{\cdot}0417 \times 10^{-8} \times 18{\cdot}617$$

$$= \mathbf{1{\cdot}94 \times 10^{-7} \text{ kg C}^{-1}}$$

Type C. On Faraday constant

Problem 4.08. A steady current of 10·0 A is maintained in a copper voltameter. Calculate the time required to deposit 2·5 g of copper. Relative atomic mass of copper = 63·5. (Take F = 96500 C mol^{-1}.

(C.B.S.E. 1991 ; Pre-degree Kerala, 1991)

Sol. Here, m = 2·5 g ; I = 10·0 A ; F = 96500 C mol^{-1} ; relative atomic mass of copper = 63·5 ; valency = 2

Therefore, chemical equivalent of copper,

$$E = \frac{63{\cdot}5}{2} = 31{\cdot}75 \text{ g mole}^{-1}$$

Now, $$m = z\,I\,t = \frac{E}{F} I\,t$$

or $$t = \frac{m\,F}{E\,I} = \frac{2{\cdot}5 \times 96500}{31{\cdot}75 \times 10{\cdot}0} = 759{\cdot}8 \text{ s}$$

Problem 4.09. In a copper plating experiment, the difference between final and initial mass of the cathode is measured carefully and is found to be 16·43 g. The time duration of electrolysis is noted to be 4000 s. The steady reading of current in an ammeter placed in series with the voltameter is 12·6 A. What is the error in the ammeter reading ? (F = 96485 C mol^{-1}, relative atomic mass of Cu = 63·54).

Sol. Here, m = 16·43 g ; t = 4000 s ; F = 96485 C mol^{-1} ; atomic mass of Cu = 63·54 ; valency of copper = 2

Therefore, chemical equivalent of copper,

$$E = \frac{63{\cdot}54}{2} = 31{\cdot}77 \text{ g mole}^{-1}$$

Now, $$m = z\,I\,t = \frac{E}{F} I\,t$$

or $$I = \frac{m\,F}{E\,t} = \frac{16{\cdot}43 \times 96485}{31{\cdot}77 \times 4000} = 12{\cdot}474 \text{ A}$$

The value of current as noted from the ammeter = 12·6 A

Therefore, error in the ammeter reading

= 12·6 – 12·474 = **0·126 A (reads more)**

Problem 4.10. A steady potential difference of 1·62 V is maintained across two platinum electrodes placed in a solution of CuCl$_2$. At the end of 600 s, the mass of copper deposited on the cathode is measured to be 5·92 g. The back e.m.f. of the voltameter is given to be 1·34 V. Estimate the resistance of voltameter. Faraday constant = 96500 C mol^{-1}, relative atomic mass of copper = 63·5.

Sol. Here, t = 600 s ; m = 5·92 g ; F = 96500 C mol^{-1}

Steady potential difference applied = 1·62 V;

back e.m.f. produced = 1·34 V

Therefore, net e.m.f. of the voltameter,

$$V = 1{\cdot}62 - 1{\cdot}34 = 0{\cdot}28 \text{ volt}$$

Atomic mass of copper = 63·5 ; valency of copper = 2

Therefore, chemical equivalent of copper,

$$E = \frac{63{\cdot}5}{2} = 31{\cdot}75 \text{ g mole}^{-1}$$

Now, $$m = z\,I\,t = \frac{E}{F} I\,t$$

or $$I = \frac{m\,F}{E\,t} = \frac{5{\cdot}92 \times 96500}{31{\cdot}75 \times 600} = 29{\cdot}99 \text{ A}$$

Therefore, resistance of the voltameter,

$$R = \frac{\text{net e.m.f.}}{I} = \frac{0{\cdot}28}{29{\cdot}99} = 9{\cdot}34 \times 10^{-3}\ \Omega = \mathbf{9{\cdot}34\ m\Omega}$$

Type D. On Charging of storage battery

Problem 4.11. A storage battery of e.m.f. 8 V, internal resistance 1 Ω is being charged by a 120 V d.c. source using a 15 Ω resistor in series in the circuit. Calculate (*a*) the current in the circuit, (*b*) terminal voltage across the battery during charging and (*c*) chemical energy stored in the battery in 5 minutes. *(C.B.S.E. 2001)*

Sol. Fig. 4.09 shows the circuit used to charge a storage battery of e.m.f. E and internal resistance r with the help of source of e.m.f. E′ and external resistance R.

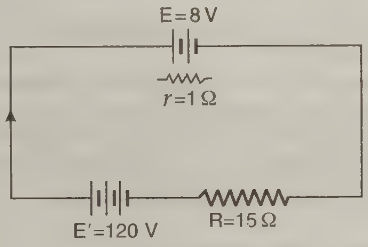

Fig. 4.09

Here, E = 8 V ; r = 1 Ω ; R = 15 Ω,
E′ = 120 V and t = 5 minutes = 5 × 6 = 300 s

(*a*) Let I be current in the circuit. Then,

$$I = \frac{\text{net e.m.f.}}{\text{total resistance}} = \frac{120 - 8}{15 + 1} = \mathbf{7\ A}$$

(*b*) Since current due to d.c. source flows into the storage cell, the potential difference across the internal resistance of the storage cell aids its e.m.f. Therefore, terminal voltage across the battery during charging,

$$V = E + I\,r = 8 + 7 \times 1 = \mathbf{15\ V}$$

(*c*) The total energy supplied by the d.c. source,

$$E'\,I\,t = 120 \times 7 \times 300 = 252000 \text{ J}$$

The energy dissipated as heat,

$$I^2 (R + r) \cdot t = (7)^2 \times (15 + 1) \times 300 = 235200 \text{ J}$$

Therefore, energy stored in the battery

= energy supplied by the d.c. source
– energy dissipated as heat
= 25200 0– 235200 = **16800 J**

Alternative method

The energy stored in the battery,

$$E\,I\,t = 8 \times 7 \times 300 = \mathbf{16800\ J}$$

TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 4.12. A steady current of 10·0 A is passed through a water voltameter for 300 s. Estimate the volume of H_2 evolved at standard temperature and pressure. Use the value of Faraday constant as 96500 C mol^{-1}. Relative molecular mass of H_2 is 2·016 and molar volume = 22·4 litres (volume of 1 mole of an ideal gas at S.T.P.).

(Text Problem)

Sol. Here, I = 10·0 A ; t = 300 s

Therefore, charge passed, $q = It = 10{\cdot}0 \times 300 = 3000$ C

Molar mass of hydrogen = 2·016

Hydrogen molecule is diatomic.

$$\text{Therefore, atomic mass of hydrogen} = \frac{2\cdot016}{2} = 1\cdot008$$

Valency of hydrogen = 1

Therefore, chemical equivalent of hydrogen,

$$E = \frac{1\cdot008}{1} = 1\cdot008 \text{ g mole}^{-1}$$

Therefore, charge required to liberate one molar mass of

$$\text{hydrogen} = \frac{96500}{1\cdot008} \times 2\cdot016 = 96500 \times 2 \text{ C}$$

Now, one molar mass of hydrogen at S.T.P. occupies volume = 22·4 litres

Therefore, volume of hydrogen evolved at S.T.P. on passing 3000 C of charge,

$$V = \frac{22\cdot4}{96500 \times 2} \times 3000 = \mathbf{0\cdot3482\ litre}$$

Problem 4.13. The potential difference across the terminals of a battery of e.m.f. 12 V and internal resistance 2 Ω drops to 10 V, when it is connected to a silver voltameter. Calculate the silver deposited at the cathode in half an hour. Atomic weight of silver is107·9 g mol^{-1}.

(C.B.S.E. 1998)

Ans. Here, atomic weight of silver = 107·9 g mol^{-1}

E.M.F. of battery, E = 12 V ;

Internal resistance of the battery, r = 2 Ω

Terminal potential difference of the battery on connecting the voltameter, V = 10 volt

If R is resistance offered by silver voltameter, then

$$r = \frac{E - V}{V} \times R$$

or

$$R = r \times \frac{V}{E - V} = \frac{12 \times 10}{12 - 10} = 10\ \Omega$$

Therefore, current passing through the silver voltameter,

$$I = \frac{E}{R + r} = \frac{12}{10 + 2} = 1 \text{ A}$$

Since valency of silver is 1, its chemical equivalent is given by

$$E = \frac{\text{atomic weight}}{\text{valency}} = \frac{107\cdot9}{1} = 107\cdot9 \text{ g mol}^{-1}$$

We know that Faraday constant, F = 96500 C mol^{-1}

Therefore, electrochemical equivalent of silver,

$$z = \frac{E}{F} = \frac{107\cdot9}{96500} \text{ g C}^{-1}$$

If m is mass of silver deposited in half an hour *i.e.* 180 s, then

$$m = zIt = \frac{107\cdot9}{96500} \times 1 \times 1800 = \mathbf{2\cdot01\ g}$$

Problem 4.14. In a silver plating system, an electrolysi current of 5·0 A is used for a certain time and 0·5 mo of silver is deposited. How many moles of copper and iro will be deposited in their respective plating system, if a electrolysis current of 10·0 A is passed for twice the time fo silver plating ? (Relative atomic mass of silver = 107· of copper = 63·54, of iron = 55·85). Take Faraday constar as 96500 C mol^{-1}.

(Text Problem

Sol. *For silver* : Here, I = 5· 0A ;

silver deposited = 0·5 mole

Silver is monoatomic and its valency is 1. Therefore, it molar mass is same as its chemical equivalent.

Now, charge required to liberate 0·5 mole (0·5 chemica equivalent) of silver,

$$q = 96500 \times 0\cdot5 \text{ C}$$

Now, $\quad q = It$

Therefore, time for which current is passed,

$$t = \frac{q}{I} = \frac{96500 \times 0\cdot5}{5\cdot0} = 9650 \text{ s}$$

For copper : Here, I = 10 A ; t = 9650 × 2 s ;

atomic mass of copper = 63·54 ; valency = 2

Therefore, chemical equivalent,

$$E = \frac{63\cdot54}{2} \text{ g mole}^{-1}$$

$$\text{Now, } m = zIt = \frac{E}{F}It = \frac{63\cdot54 \times 10 \times 9650 \times 2}{2 \times 96500} = 63\cdot54 \text{ g}$$

Since copper is monoatomic, therefore, its molar mass i equal to its atomic mass *i.e.*63·54.

Hence, **one mole** of copper will be liberated.

For iron : Here, I = 10 A ; t = 9650 × 2 s ;

atomic mass of iron = 55·85, valency = 3

Therefore, chemical equivalent,

$$E = \frac{55\cdot85}{3} \text{ g mole}^{-1}$$

$$\text{Now,} \quad m = \frac{E}{F}It = \frac{55\cdot85 \times 10 \times 9650 \times 2}{3 \times 96500} = \frac{2}{3} \times 55\cdot85 \text{ g}$$

Since iron is monoatomic, its molar mass is also 55·85.

Hence, $\frac{2}{3}$ **mole** of iron will be deposited.

FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 4.01. Are all pure liquids bad conductors of electricity ?

Ans. All pure liquids are not bad conductors of electricity. For example, mercury in pure form is a liquid and is a goo conductor of electricity.

Q. 4.02. What is electrolysis ? *(P.S.S.C.E. 1999*

Ans. Refer to section 4.03.

Q. 4.03. Name the liquid, which is good conductor of electricity but does not undergo electrolysis on passage of the electric current.

Ans. Mercury is a liquid which is good conductor of electricity and it does not undergo electrolysis on passing current through it.

Q. 4.04. What is difference between a voltameter and a voltmeter ? *(P.S.S.C.E. 1999, 1998 S)*

Ans. Whereas voltmeter is an instrument used to measure potential difference, voltameter is a vessel used to carry out electrolysis of an electrolyte.

Q. 4.05. What are the carriers of current in a copper voltameter normally ? *(P.S.S.C.E. 1997 S)*

Ans. Normally, Cu^{++} and SO_4^{--} ions are considered as carriers of current in a copper voltameter.

Note. In a copper voltameter, the electrolyte is copper sulphate dissolved in water. Copper sulphate dissociates into Cu^{++} and SO_4^{--} ions, while water dissociates into H^+ and OH^- ions. Therefore, in a copper voltameter, the carriers of current are Cu^{++}, H^+, SO_4^{--} and OH^- ions.

Q. 4.06. What are cations ? *(H.P.S.S.C.E. 2000)*

Ans. *The positive ions, which collect at cathode during the process of electrolysis, are called cations.*

Q. 4.07. What are anions ? *(H.P.S.S.C.E. 2000)*

Ans. *The negative ions, which collect at anode during the process of electrolysis, are called anions.*

Q. 4.08. If pure water is used, no electrolysis takes place. Why ?

Ans. It is because, pure water does not dissociate into ions.

Q. 4.09. Are the drift speeds of positive and negative ions equal to each other in the electrolysis of an electrolyte ? *(H.S.S.C.E. 1992)*

Ans. The drift speeds of positive and negative ions are not equal in the electrolysis of an electrolyte.

Q. 4.10. Explain V – I graph for a copper voltameter. *(P.S.S.C.E. 2001 ; C.B.S.E. 2001 S)*

Ans. The V – I graph for the copper voltameter is a straight line [Fig. 4.10]. It indicates that the electrolyte used in copper voltameter obeys Ohm's law. It may be pointed that V – I graph remains a straight line, till the current is made not too high.

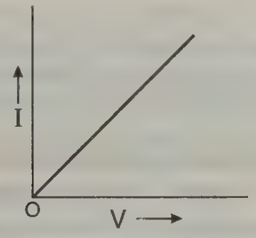

Fig. 4.10

Note. In a copper voltameter, no back e.m.f. is produced in general. The electrolytes obey Ohm's law, if the applied voltage is greater than the back e.m.f.

Q. 4.11. How is the electrical conductivity of an electrolyte affected by increase of temperature ? *(P.S.S.C.E. 2001, C.B.S.E. 1995)*

Ans. Due to increase of temperature, the electrical conductivity of an electrolyte increases (resistance of electrolyte decreases).

Q. 4.12. Draw the graph showing variation of mass of ions deposited with time during electrolysis, when a steady current is passed during the process. *(C.B.S.E. 2002)*

Ans. From Faraday's first law of electrolysis

$$m = z\,I\,t$$

When a steady current is passed during electrolysis,

$$m = \text{constant} \times t$$

The above equation represents a straight line. Hence, graph between mass of ions deposited with time will be a straight line, when steady current is passed during electrolysis. [Fig. 4.11]

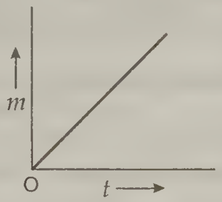

Fig. 4.11

Q. 4.13. Fig. 4.12 shows mass deposited (m) versus time (t) graph of a voltameter for two currents I_1 and I_2. Is I_1 more than, less than or equal to I_2 ?

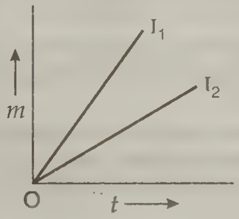

Fig. 4.12

Ans. From Faraday's first law of electrolysis,

$$m \propto I$$

From Fig. 4.12, it follows that in a given time, mass deposited is more for current I_1 than I_2. Hence, current I_1 is greater than current I_2.

Q. 4.14. Are electrochemical equivalent and chemical equivalent of a substance same ? *(H.S.S.C.E. 1992)*

Ans. No, electrochemical equivalent and chemical equivalent of a substance are not the same quantities.

Q. 4.15. Define Faraday constant. *(P.S.S.C.E. 2002 ; H.S.S.C.E. 2000)*

Or

Define one faraday of charge. *(H.S.S.C.E. 1995)*

Ans. *One faraday is the quantity of charge required to liberate one gram equivalent of the substance on an electrode during the process of electrolysis.* It has a value of 96500 coulomb mole^{-1}.

Q. 4.16. Can we make use of a.c. in electrolysis ? Explain briefly. *(H.P.S.S.C.E. 2000, 1998 S)*

Or

Why can't we use alternating current for producing electrolysis ? *(P.S.S.C.E. 1998)*

Ans. No, we cannot use a.c. for carrying out electrolysis. If a.c. is used, the electrolysis will take place alternately in opposite directions and hence no deposit of ions will take place on any electrode.

Q. 4.17. Name a few practical applications of the phenomenon of electrolysis.

Ans. A few practical applications of electrolysis are electroplating, purification of metals, chemical analysis, electrolytic capacitors, etc.

Q. 4.18. Does electromotive force have units of force ?

Ans. No, electromotive force does not have the unit of force. It has the unit of work done per unit charge.

Q. 4.19. What is the most important property of a standard cell ? *(I.S.C.E. 1997)*

Ans. The standard cell is one, whose e.m.f. does not vary practically with time and temperature.

Q. 4.20. Name a few primary cells.

Ans. Simple voltaic cell, Daniel cell, Leclanche cell, Bunsen cell.

Q. 4.21. Name the electrolyte in a simple voltaic cell.

Ans. In a simple voltaic cell, the dilute sulphuric acid is used as electrolyte.

Q. 4.22. Mention two defects of a voltaic cell. *(C.B.S.E. 2001; H.S.S.C.E. 1999)*

Ans. Local action and polarisation.

Q. 4.23. What is ploarisation in a simple voltaic cell ? *(P.S.S.C.E. 2002)*

Ans. When the H^+ ions reach the copper rod in a simple voltaic cell, they extract electrons from it so as to form hydrogen atoms. It results in the formation of a neutral layer of hydrogen gas on the copper rod, which weakens the action of the cell.

Q. 4.24. Name the metals, which are used to make a positive and negative poles in a (*i*) Daniel cell (*ii*) Leclanche cell.

Ans. In both the cells, zinc is used to make negative pole of the cell. Whereas in Daniel cell, copper is used to make positive pole, carbon is used to make the positive pole in Leclanche cell.

Q. 4.25. Name the electrodes, which act as anode and cathode in a Daniel cell.

Ans. In a Daniel cell, the copper vessel acts as cathode, while zinc rod acts as anode.

Q. 4.26. Name the depolarisers in Daniel cell and Leclanche cell.

Ans. Copper sulphate solution and manganese dioxide respectively act as depolarisers in Daniel and Leclanche cell.

Q. 4.27. Give the role of MnO_2 in a dry cell. *(C.B.S.E. 2002 ; P.S.S.C.E. 2001)*

Or

What is the function of MnO_2 in Leclanche cell ? *(P.S.S.C.E. 2002 ; H.S.S.C.E. 1998 S)*

Ans. By converting hydrogen gas into water, MnO_2 prevents hydrogen gas from causing the defect of polarisation. As such, MnO_2 is said to act as depolariser.

Q. 4.28. What is a dry cell ?

Ans. A dry cell is portable form of a Leclanche cell.

Q. 4.29. What is the function of saw dust in a dry cell ? *(P.S.S.C.E. 1999*

Ans. To keep ammonium chloride moistened.

Q. 4.30. You are given a primary and a secondary cel of the same e.m.f. From which cell, will you be able to drav larger current and why ? *(C.B.S.E. 1994*

Ans. As the internal resistance of a secondary cell is les than that of a primary cell, the secondary cell will provide higher value of current.

Q. 4.31. Name the carriers of electric current in a voltai cell and a lead accumulator. *(Text Question*

Ans. Both in voltaic cell and a lead accumulator (bein charged by an external supply), the carriers of electric curren are H^+ and SO_4^{--} ions.

Q. 4.32. Which type of cell would you want to use, i your device required (*i*) a current of 100 A for 20 s (*ii*) current of 10 mA occasionally ? *(Text Question*

Ans. (*i*) A lead accumulator having very low interna resistance. (*ii*) A dry cell.

Q. 4.33. What do you mean by capacity of a storag cell ?

Ans. The capacity of a storage cell implies its ability t supply electrical energy.

Q. 4.34. Define the unit for measuring the capacity o a storage cell ?

Ans. The capacity of a storage cell is measured i ampere-hour.

Storage capacity of a cell is called one ampere hour, if it ca supply one ampere of current for one hour continuously.

Q. 4.35. A storage battery is marked a capacity of 3·5 h at 1 h discharge rate. What does this signify ? Would th cell provide 14 A for 15 minutes ?

Ans. It indicates that the storage battery can supply current of 3·5 A for 1 hour. If a large current is drawn, th battery exhausts at a faster rate than expected. Therefore, i will not provide 14 A current for 15 minutes.

Q. 4.36. Under what condition, can we draw maximun current from a secondary cell ? *(C.B.S.E. 2001*

Ans. The maximum current can be drawn from secondary cell, when its internal resistance is minimum.

Note. The power consumed in the circuit will b maximum, when external load (resistance) is equal to interna resistance of the secondary cell.

FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 4.01. What is the difference between the electric conduction in the solutions and metals ?

Ans. The conduction of electricity in metals is due to the drift of free electrons, while the conduction of electricity in electrolyte is due to the movement of positive and negative ions. Further, during electric conduction, whereas no chemical change takes place in metals ; the chemical decomposition takes place in electrolytes. Further, whereas no matter is transported during electric conduction in metals, matter is transported in the form of positive and negative ions in case of electrolytes.

Q. 4.02. Conductivity of electrolytic solutions is much lower as compared to that of the metals. Give reasons. *(C.B.S.E. 1999 S, 1996*

Ans. 1. Number of ions in electrolytes is very small a compared to number of free electrons in metallic conductors

2. Due to large mass, the mobility of ions in electrolyte is very low as compared to that of electrons in metalli conductors.

Q. 4.03. Why is the conductivity of molten electrolyte smaller than common metallic conductors ? *(C.B.S.E. 1998 S*

Ans. A solid electrolyte, such as NaCl dissociates into ions but it cannot conduct electricity. It is because, its ions are not mobile as such. When NaCl is in molten state, the ions acquire a small mobility. Hence, it can conduct electricity, which is very small as compared to that of metallic conductor. It may be pointed out that the conductivity of NaCl further increases on dissolving it in water.

Q. 4.04. What are conductors of the second kind ?

Ans. The electrolytes, in which the current is conducted through the ions, are called the conductors of the second kind. The metals are called the conductors of the first kind. The current is conducted in metallic conductors by the free electrons.

Q. 4.05. Briefly explain the dissociation theory of electrolysis. *(H.S.S.C.E. 2001)*

Ans. Refer to section 4.04.

Q. 4.06. Why are electrolytes dissociated, when dissolved in liquids ? *(H.S.S.C.E. 2001)*

Ans. The polar molecules of a liquid, such as water have a large value of dielectric constant (≈ 80). When an electrolyte is dissolved in a liquid, the ionic bonds between the ions of the electrolyte become very weak. Then, the thermal energy of the ions takes the ions away from each other leading to the dissociation of the electrolyte.

Q. 4.07. Explain the theory of electrolysis. *(H.S.S.C.E. 2001)*

Ans. Refer to section 4.04.

Q. 4.08. Explain, what do you understand by back e.m.f. in an electrolytic cell.

Ans. The e.m.f. that exists due to contact difference of potential between two different materials is called back e.m.f. It sends a current through the electrolyte in a direction opposite to that sent by the externally applied e.m.f.

Q. 4.09. The anode of the silver voltameter is made of silver. Why ?

Ans. When current is passed through silver nitrate in silver voltameter, silver ions (Ag^+) move towards cathode and nitrate ions (NO_3^-) towards anode. The silver ions deliver charge on the silver cathode and become silver atoms. On the other hand, nitrate ions on reaching the anode form silver nitrate, which goes into the silver nitrate solution. In this manner, whereas the concentration of electrolyte is maintained, the mass of cathode increases and that of anode decreases. So that this process goes on, it is essential that in a silver voltameter, anode should be made of silver.

Q. 4.10. State Faraday's laws of electrolysis. *(H.S.S.C.E. 2002 ; H.P.S.S.C.E. 2001, 1999 S ; P.S.S.C.E. 1999 S ; C.B.S.E. 1994, 1991, 1990)*

Ans. For Faraday's laws of electrolysis, refer to section 4.07.

Q. 4.11. Draw a neat labelled diagram of a copper voltameter. Define electrochemical equivalent of a substance. *(H.S.S.C.E. 2002)*

Ans. For diagram of copper voltameter, refer to Fig. 4.01.

Electrochemical equivalent of a substance. *It may be defined as the mass of the substance deposited at the cathode, when one coulomb of charge passes through the electrolyte.*

Q. 4.12. Define electrochemical equivalent. Give its units. *(C.B.S.E. 1992)*

Ans. Refer to SAQ 4.11.

Q. 4.13. In two voltameters with different electrolytes in solution, same mass is deposited when the currents in the two are in the ratio of 1 : 2 and times of deposit are in the ratio of 2 : 3. What is the ratio of electrochemical equivalents of the electrolytes in the two cases ? *(C.B.S.E. 2001 S)*

Ans. From Faraday's first law of electrolysis,

$$m = z\,I\,t$$

Let I_1 and I_2 be the currents passed for times t_1 and t_2 respectively through the two electrolytes. Further, let z_1 and z_2 be their electrochemical equivalents. Since same mass of the ions is deposited in the two cases,

$$z_1 I_1 t_1 = z_2 I_2 t_2 \quad \text{or} \quad \frac{z_1}{z_2} = \frac{I_2}{I_1} \times \frac{t_2}{t_1}$$

$$\text{Here,} \quad \frac{I_1}{I_2} = \frac{1}{2} \quad \text{and} \quad \frac{t_1}{t_2} = \frac{2}{3}$$

$$\textit{i.e.} \quad \frac{I_2}{I_1} = 2 \quad \text{and} \quad \frac{t_2}{t_1} = \frac{3}{2}$$

$$\therefore \quad \frac{z_1}{z_2} = 2 \times \frac{3}{2} = 3$$

Hence, the ratio of electrochemical equivalents of the two electrolytes is **3 : 1.**

Q. 4.14. Explain, how you can use a voltameter for measuring current. *(P.S.S.C.E. 1992)*

Ans. A voltameter can be used to measure current indirectly. Suppose that on passing current through an electrolyte for a known time t, the increase in mass of the cathode is m. Then,

$$m = z\,I\,t,$$

where z is electrochemical equivalent of the substance. It follows that

$$I = \frac{m}{z\,t}$$

Knowing m, t and z, the value of current passed through the electrolyte can be calculated.

Q. 4.15. A voltameter measures current more accurately than an ammeter. Why ?

Ans. A voltameter measures current indirectly in terms of mass of ions deposited and E.C.E. of the substance

$$\left(I = \frac{m}{z\,t} \right)$$

Since values of m and z are measured to 3rd decimal place (upto one milligram) and 5th decimal place (refer to the values of z from tables) respectively, the relative error in the measurement of current by voltameter will be very small as compared to that when measured by ammeter directly.

Q. 4.16. How can the accuracy of a given ammeter be determined with the help of copper voltameter. *(P.S.S.C.E. 1999 S ; C.B.S.E. 1998 S)*

Ans. By passing current for a known time t, mass of copper deposited on the cathode is measured. Since $m = z\,I\,t$, we have

$$I = \frac{m}{z\,t}$$

Knowing m, t and z (electrochemical equivalent of copper), the current I flowing through the voltameter can be calculated. The comparison of the calculated value of current

I with the value noted from the ammeter gives the accuracy of the ammeter.

Q. 4.17. How the process of electrolysis can be used to find zero error in an ammeter ?

Ans. As explained above, the current passed through an electrolyte can be calculated by noting m, t and z in an experiment. If the ammeter is also put in the circuit, the difference in the calculated value of I and the reading of ammeter gives the zero zero for the ammeter.

Q. 4.18. State and explain Faraday's second law of electrolysis. *(H.S.S.C.E. 2002)*

Ans. Refer to section 4.07.

Q. 4.19. Define chemical equivalent and electrochemical equivalent of a substance. Establish the relationship between the two.

(C.B.S.E. 1997 ; H.P.S.S.C.E. 1997)

Ans. Chemical equivalent. *The chemical equivalent of an element is defined as the ratio of its atomic weight to the valency of its atom.*

$$\text{Thus, chemical equivalent, } E = \frac{\text{atomic weight}}{\text{valency}}$$

Electrochemical equivalent. *Electrochemical equivalent of a substance may be defined as the mass of ions liberated, when one coulomb of charge passes through the electrolyte.*

For relation between chemical equivalent and electrochemical equivalent, refer to section 4.07.

Q. 4.20. What is electrolysis ? What is the relation between electrochemical equivalent and chemical equivalent of a substance ? *(H.S.S.C.E. 2002)*

Ans. Electrolysis. *The process of liberating free elements from an electrolytic solution, when electric current is passed through it, is called electrolysis.*

Relation between electrochemical equivalent and chemical equivalent. It is given by

$$\frac{E}{z} = \text{constant}$$

Q. 4.21. Define Faraday constant. How is it related to E.C.E. of a substance ?

Ans. For definition of Faraday constant, refer to section 4.08.

Faraday constant and E.C.E. of a substance are related to each other by the relation

$$z = \frac{E}{F},$$

where E is chemical equivalent of the substance.

Q. 4.22. Explain the process of electroplating.

(P.S.S.C.E. 2002)

Ans. Refer to section 4.09.

Q. 4.23. What is the difference between primary and secondary cells ? Give one example of each.

(P.S.S.C.E. 2002, 1994 ; H.S.S.C.E. 2002 ; Pre-degree Kerala, 1991)

Ans. An electrochemical cell, which cannot be recharged and the chemicals have to be replaced, is called a primary cell.

On the other hand, an electrochemical cell in which the chemicals of the cell can be recharged again and again is called a secondary cell. A Leclanche cell is an example of a primary cell, while a lead-acid cell is a secondary cell.

Q. 4.24. Name the two defects of a simple voltaic cell. How these defects can be eliminated ? *(P.S.S.C.E. 1996)*

Ans. A voltaic cell suffers from the two defects name local action and polarisation.

For removal of these defects, refer to section 1.05.

Q. 4.25. What do you mean by local action in a volt cell ? How is it elliminated ? *(H.S.S.C.E. 20*

Ans. The zinc rod used in the voltaic cell contains tra of iron and lead. When such a zinc rod is dipped in dil sulphuric acid, tiny voltaic cells are formed locally on the z rod. Due to the electric currents set up in these local cells, z is converted into $ZnSO_4$, even when the cell is not in use. T defect in a voltaic cell is called local action.

Q. 4.26. Draw a labelled diagram of a Daniel cell.

(H.S.S.C.E. 2002, 2001 ; P.S.S.C.E. 1999 S ; C.B.S.E. 19

Ans. Refer to Fig. 4.04.

Q. 4.27. Draw a labelled diagram of Daniel cell. W is the function of copper sulphate and sulphuric a solutions used in it ? *(C.B.S.E. 19*

Ans. For labelled diagram, refer to Fig. 4.04.

In a voltaic cell, a neutral layer of hydrogen gas is forn on the copper rod (anode). It weakens the action of the cell a this defect in voltaic cell is called polarisation.

However, it does not happen so in a Daniel cell, wl dilute sulphuric acid and copper sulphate solutions are us In this cell, the hydrogen ions formed due to the reactior zinc with dilute sulphuric acid, react with copper sulph solution so as to form sulphuric acid again. As such, polarisation due to hydrogen can take place due to the use copper sulphate solution. The copper sulphate solution is s to act as depolariser.

Q. 4.28. Draw a labelled diagram of Leclanche cell

(H.S.S.C.E. 2002, 2001 ; P.S.S.C.E. 1999

Ans. Refer to Fig. 4.05.

Q. 4.29. Draw labelled diagram of a Leclanche c Write the function of charcoal and manganese dioxide u in its porus pot. *(P.S.S.C.E. 1999 S ; C.B.S.E. 19*

Ans. For labelled diagram, refer to Fig. 4·05.

In a Leclanche cell, manganese dioxide is used depolariser. The hydrogen ions formed due to the reactior zinc with ammonium chloride solution enter the porus through its pores. Inside the porus pot, the hydrogen ions re with MnO_2 to form Mn_2O_3. However, by taking oxygen fr the atmosphere, Mn_2O_3 gets oxidised to MnO_2 again. T charcoal powder is used in order to make manganese diox electrically conducting and its use helps in decreasing internal resistance of the cell.

Q. 4.30. A Leclanche cell is used, when constant sup of electric current is not required. Why ?

Ans. The e.m.f. of a Leclanche cell falls, if it is u continuously. It is because of the partial polarisation due accumulation of hydrogen gas. In case, Leclanche cell is u in experiments, where current is drawn after short brea then during each break, hydrogen gas escapes and Mn converts into MnO_2 by taking oxygen from the atmosph As a result, the cell regains its original e.m.f.

Q. 4.31. Draw a neat, labelled diagram of a dry cell

(H.S.S.C.E. 20

Ans. Refer to Fig. 4.06.

Q. 4.32. Why a series resistance is put while charg a storage cell ?

Ans. In case, a large current flows through the storage cell during charging, then a non-porous layer of $PbSO_4$ is formed on the plates, which does not decompose during subsequent recharging. As a result, the storage cell is rendered useless.

Q. 4.33. A storage cell should not be short circuited. Why ?

Ans. During short circuiting, a large current flows through the cell and as said in SAQ 4.32, a non-porous layer of $PbSO_4$ is formed. This layer does not decompose during charging and the cell is rendered useless.

Q. 4.34. Why is the terminal voltage across a battery more than its e.m.f. during recharging ? (*C.B.S.E. 1998 S*)

Ans. During charging, the positive plate of the accumulator is connected to positive terminal and its negative plate to the negative terminal of the battery charger. As a result, the terminal voltage across the battery becomes more than its e.m.f.

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For **a**mbitious, **b**rilliant & **c**urious Students

Q. 4.01. Molten sodium chloride conducts electricity, while sodium chloride below its boiling point is non-conducting liquid. Why ? (*Text Question*)

Ans. Sodium chloride is ionic in solid state. But in the solid state, ions are bound. When sodium chloride is in molten state, the ions become free to move. Due to this reason, molten sodium chloride conducts electricity.

Q. 4.02. The solution of HCl in water is strongly conducting. Why ? (*Text Question*)

Ans. HCl is not ionic and therefore in molten state, it is not conducting. When HCl is dissolved in water, the hydrogen molecules having great affinity for H_2O molecules, react with water and Cl^- ions are set free. As a result, the solution of HCl in water becomes strongly conducting.

Q. 4.03. Why do some covalent salts (e.g. Al_2Cl_6), which are not ionic in solid state, become conducting, when dissolved in water ? (*Text Question*)

Ans. Some covalent salts, which are not ionic and hence non- conducting become conducting when dissolved in water. The reason is that the metal ions in covalent salts have strong affinity for water and react with water. The ions other than metal ions in the salts are set free. These ions act as current carriers. It explains how the covalent salts when dissolved in water become conducting.

Q. 4.04. What is a strong electrolyte and a weak electrolyte ? Give examples. (*Text Question*)

Ans. Strong electrolytes. *Those electrolytes, which are more or less completely ionised in their solutions are called strong electrolytes.* For example, HCl, NaOH and NaCl.

Weak electrolytes. *Those electrolytes, which are ionised to a small extent in their solutions are called weak electrolytes.* For example, NH_4Cl, CH_3COOH and H_2CO_3.

Q. 4.05. What causes the dissociation of the solute molecules in the solution ? (*Text Question*)

Ans. The ionic bonds between the ions of the solute are weakened by the polar molecules of the solvent like water. Due to this, the ions of the solute get dissociated. The chaotic motion of the solvent and solute molecules helps in the process of dissociation.

Q. 4.06. Define international ampere.

Ans. In 1910, the International Conference of Weights and Measures defined the unit of current (ampere) on the basis of the electrolysis of the silver salt and ampere defined in this manner is called international ampere.

From Faraday's first law of electrolysis, we have

$$m = z\,I\,t$$

Suppose that $I = 1$ ampere, $t = 1$ s

Then, $m = z \times 1 \times 1 = z$

Now, value of z for silver is 0·001118 g C^{-1}.

Hence, *international ampere is defined as the steady current, which when passed through a silver voltameter, deposits 0·001118 g of silver in one second on the cathode.*

Q. 4.07. A simple voltaic cell has an e.m.f. equal to 0·1 V. When the circuit is open, is there a net field, which would give rise to a force on a test charge (*i*) inside the electrolyte of the cell (*ii*) outside the cell ? (*Text Question*)

Ans. (*i*) Inside the cell, there are two fields. One field is the electrostatic field between the plates due to the e.m.f. of the cell and another field is of non-electrostatic origin. However, the two fields just balance each other and consequently net field inside the cell is zero.

(*ii*) Outside the cell, the net field is the electrostatic field between the two plates of the cell.

Q. 4.08. Consider a voltaic cell in open circuit with copper plate at higher potential w.r.t. zinc plate. Since the electrolyte separating them is a conducting medium, why are the positive and negative charges on the electrodes not neutralized immediately ? (*Text Question*)

Ans. The positive and negative charges on the two electrodes are prevented from being neutralized by the non-electrostatic field existing inside the cell. The electrostatic field is opposed by the non-electrostatic field.

Q. 4.09. During the action of voltaic cell, copper rod is positively charged and zinc rod is negatively charged. However, copper rod is called cathode and zinc rod is called anode. Why ?

Ans. The electrode of the cell, at which oxidation reaction (release of electrons) takes place is called anode ; while the electrode, at which reduction reaction (addition of electrons) takes place is called cathode.

Since in voltaic cell, oxidation and reduction reactions take place at zinc and copper rods respectively, zinc rod is called anode and the copper rod is said to act as cathode.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. Give the ionic theory of electrolysis.
2. Explain the terms : electrode, anode, cathode, anion, cation, electrolyte, chemical equivalent, gram equivalent, electrochemical equivalent and faraday.
3. What are (*i*) copper voltameter (*ii*) silver voltameter (*iii*) water voltameter ? Discuss.

4. What is electrolysis ? State its laws. (*P.S.S.C.E. 2002, 2000*)
5. State and explain Faraday's laws of electrolysis. (*H.P.S.S.C.E. 2000 ; P.S.S.C.E. 1999 ; H.S.S.C.E. 1997 S, 1997*)
6. State Faraday's laws of electrolysis. Draw a labelled circuit diagram to illustrate deposition of copper on a given metallic object. (*C.B.S.E. 1995*)
7. What is electrolysis ? State and explain Faraday's laws of electrolysis. (*P.S.S.C.E. 2001*)
8. State Faraday's law of electrolysis. Derive the relation connecting chemical equivalent and electrochemical equivalent of an element. (*C.B.S.E. 1999, 1996*)
9. State Faraday's laws of electrolysis. How is Faraday constant related to E.C.E. of a substance ? (*H.P.S.S.C.E. 1996*)
10. Prove that Faraday constant $F = \frac{qE}{m}$ and hence define Faraday constant. (*H.P.S.S.C.E. 2002*)
11. Define Faraday constant. How is Faraday constant related to E.C.E. of a substance ? (*P.S.S.C.E. 1999 ; H.P.S.S.C.E. 1996*)
12. Write notes on : (*a*) Electroplating (*b*) Refining of metals by electrolysis.
13. What is an electrochemical cell ? What is the differen
between primary and secondary cells ? Give one examp
of each type. (*H.S.S.C.E. 1998 ; P.S.S.C.E. 1998, 1997, 199*
14. Write two advantages and two disadvantages of a seco
dary cell over a primary cell. (*C.B.S.E. 199*
15. Explain the construction and action of a simple voltaic ce
16. What is a source of e.m.f. ? Describe the construction a
working of a Daniel cell.
17. Explain with the help of a labelled diagram, the con
truction and working of a Daniel cell. (*C.B.S.E. 199*
18. What is a primary cell ? Give the construction a
necessary theory of Leclanche cell.
19. Name the defects of voltaic cell. How are they removed
Leclanche cell ? Draw its labelled diagram.
(*P.S.S.C.E. 199*
20. Draw a labelled diagram of a Daniel cell. Write down t
chemical reactions taking place at the anode and t
cathode. (*C.B.S.E. 199*
21. Draw a labelled diagram of a dry cell. Explain its acti
with the help of chemical reactions taking place at catho
and anode.
22. With the help of a suitable diagram, explain the constru
tion and working of a dry cell. (*C.B.S.E. 199*

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. (*a*) State Faraday's laws of electrolysis and the definition of strong electrolyte. (*H.S.S.C.E. 1995*)
   (*b*) Discuss a method to determine the electrochemical equivalent of a substance.
2. (*a*) State and explain Faraday's laws of electrolysis. Define electrochemical equivalent. (*C.B.S.E. 1992*)
   (*b*) Show that the Faraday's constant is equal to the produ
   of Avogadro number and the electronic charge.
3. What is the difference between a primary and a seconda
cell ? Describe the action of a lead-acid cell with the he
of a diagram and the reactions taking place inside. Expla
in brief the charging and discharging process in a lead ac
cell.

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Faraday's first law of electrolysis

1. How long will it take to deposit 1·5 g of silver by a constant current of 0·75 A in a silver voltameter ? Given E.C.E. of silver 0·001118 $g\ C^{-1}$. [**Ans.** 29 minutes 49 seconds]
2. It is desired to deposit 0·315 kg of copper on the cathode of a copper voltameter. How long will it take to deposit this amount, if a steady current of 10 A is maintained ? Given that E.C.E. of copper $= 3{\cdot}15 \times 10^{-7}\ kg\ C^{-1}$. (*H.P.S.S.C.E. 1998 S*) [**Ans.** 1,000 s]
3. Calculate the value of current required to deposit 0·972 g of chromium in 3 hours. E.C.E. of chromium is 0·00018 $g\ C^{-1}$. [**Ans.** 0·5 A]
4. A copper voltameter and an ammeter are connected in series with a battery through a resistance. In 150 minutes, 2·97 g copper is deposited on the cathode plate. The ammeter reads 0·95 A. Calculate the error in the reading of ammeter. Given that E.C.E. of copper $= 3{\cdot}3 \times 10^{-4}\ g\ C^{-1}$. (*C.B.S.E. 2000 S*) [**Ans.** Reads 0·05 A less]
5. An ammeter is suspected to be giving incorrect reading of current. To check the error, it is connected in series with a copper voltameter. When a steady current is passed through the voltameter for one hour, 2·02 g of copper is deposited. If the ammeter reads 2 A, what is the error in it ? Given that E.C.E. of copper is 0·00033 $g\ C^{-1}$. [**Ans.** Reads 0·3 A more]
6. A steady current deposits 0·15 g of copper in 15 minutes from copper sulphate solution. An ammeter in series read 0·5 A. What is the correction to be applied to the ammeter reading ? Given E.C.E. of copper $= 3{\cdot}3 \times 10^{-4}\ g\ C^{-1}$.
(*Pre-degree Kerala, 1992*) [**Ans.** Reads 0·005 A mo
7. A silver and a copper voltameter are connected in paral
to a 12 volt battery having negligible internal resistance.
half hour, 1 g of silver and 1·8 g of copper are deposite
Calculate the rate of dissipation of energy from the batte
Given that E.C.E. of copper is $3294 \times 10^{-7}\ g\ C^{-1}$and that
silver is $11180 \times 10^{-7}\ g\ C^{-1}$. [**Ans.** 42·4 wa
8. A silver and a copper voltameter are connected in series wi
a 12·0 V battery of negligible internal resistance. 0·806 g
silver is deposited in half an hour in the silver voltamet
Calculate (*i*) magnitude of current flowing in the circuit a
(*ii*) mass of copper deposited in the copper voltamet
during the same period. Given that E.C.E. of silver 1·12
$10^{-6}\ kg\ C^{-1}$and E.C.E. of copper $= 3{\cdot}3 \times 10^{-7}\ kg\ C^{-1}$.
(*C.B.S.E. 1998*) [**Ans.** (*i*) 0·4 A (*ii*) 0·238
9. A copper voltameter is in series with a heater coil
resistance 0·3 Ω. A steady current flows in the circuit for
minutes. A mass of 0·99 g of copper is deposited at t
cathode. If the electrochemical equivalent of copper
0·00033 $g\ C^{-1}$, calculate the heat generated in the coil ?
(*C.B.S.E. 2000*) [**Ans.** 1500
10. A copper voltameter is connected in series with a coil
resistance 20 ohm. A steady current is passed through t
circuit for 10 minutes and it deposits 0·1 g of copp
Calculate the amount of heat generated in the coil. T
E.C.E. of copper is 0·000329 $g\ C^{-1}$. [**Ans.** 3079·55
11. A plate of area 10 cm^2 is to be electroplated with copp
to a thickness of 0·001 cm on both sides using a batte

of 10 volt. Calculate the energy spent in the process. Density of copper is 8·9 g cm^{-3} and E.C.E. of copper is 0·00033 g C^{-1}. **[Ans. 5393·94 J]**

12. A spoon having 10 cm^{2} area is to be electroplated with silver. A current of 0·12 A is passed for 48 hours through the electrolyte. Calculate the thickness of silver deposited. Given that density of silver = 10·5 × 10^{3} kg m^{-3} and E.C.E. of silver = 1·118 × 10^{-6} kg C^{-1} **[Ans. 2·2 mm]**

Type B. On Faraday's second law of electrolysis

13. A copper voltameter is connected in series with a silver voltameter. When same current is passed through both the voltameters for same time, 1·5 g of silver is deposited on the cathode of the silver voltameter. Calculate the copper deposited on the cathode of the copper voltameter. Take the chemical equivalents of silver and copper as 108 and 31·5 respectively. **[Ans. 0·4375 g]**

14. Two voltameters are connected in series and are arranged to deposit copper and silver respectively. How much copper will be deposited in copper voltameter, if 1 g of silver is deposited in silver voltameter. Given that chemical equivalents of copper and silver are 31·5 and 108 respectively. **[Ans. 0·292 g]**

15. Two voltameters are connected in series. One of them is water voltameter and the other is copper voltameter. How much oxygen will be liberated in the water voltameter, when 0·5 g of copper is deposited in the copper voltameter? Chemical equivalents of copper and oxygen are 32 and 8 respectively. **[Ans. 0·125 g]**

16. Find the strength of current that deposits 0·777 g of metallic copper in half an hour in a copper voltameter. The atomic weight of copper is 63, E.C.E. of hydrogen is 1·036 × 10^{-5} g C^{-1} and chemical equivalent of hydrogen is 1·008. **[Ans. 1·333 A]**

17. Find the value of Faraday constant by considering the electrolysis of NaCl. Given that atomic weight of Na = 23 and E.C.E. of Na = 2383·4 × 10^{-7} g C^{-1}. *(P.S.S.C.E. 1999)* **[Ans. 96500 C]**

Type C. On Faraday constant

18. Given that 96500 C of charge liberates 1 gram-equivalent of a substance. How long will it take for a current of 0·15 A to deposit 500 mg of copper from a copper sulphate solution ? Take chemical equivalent of copper as 32. **[Ans. 167·54 minutes]**

19. It is desired to deposit 0·54 kg of silver per hour on the cathode of silver voltameter, whose resistance is 0·72 mΩ. How much potential difference must be maintained between the plates of the voltameter during electrolysis. Use the known vlaue of Faraday constant. Relative atomic mass of silver is 108. **[Ans. 96·4 mV]**

20. A current of 1 A is passed through a dilute solution of sulphuric acid for some time to liberate 1 g of oxygen. How much hydrogen is liberated during this period ? How long was the current passed ? Given that Faraday constant = 96500 C mole^{-1}. **[Ans. 0·126 g ; 201 minutes]**

MISCELLANEOUS PROBLEMS

21. One ampere current flows for one minute through a silver voltameter. It deposits 0·067 g of silver on the cathode. Calculate (*a*) the electrochemical equivalent of silver. (*b*) How much charge will be required to deposit 108 g of silver ? (*c*) How much charge is carried by silver ion ? Given that Avogadro number = 6·024 × 10^{26} per kg mole. *(Roorkee 1981)*
[Ans. (*a*) 1·1167 × 10^{-6} kg C^{-1} (*b*) 9·67 × 10^{4} C (*c*) 1·6 × 10^{-19} C]

22. In producing chlorine through electrolysis, 100 kW power of 125 V is being consumed. How much chlorine per minute is liberated ? Given that E.C.E. of chlorine = 0·367 × 10^{-6} kg C^{-1}. *(Roorkee 1982)* **[Ans. 1·762 × 10^{-2} kg]**

23. A charged capacitor of capacitance 5 × 10^{-2} F is discharged through a resistor of 20 Ω and a copper voltameter of internal resistance 30 Ω is connected in series to it. If 4·62 × 10^{-6} kg of copper is deposited, calculate the heat generated in the resistor. Given that E.C.E. of copper = 3·3 × 10^{-7} kg C^{-1}. *(M.N.R. 1994)* **[Ans. 784 J]**

11. Mass of copper deposited,
    $$m = (2\ \text{A}) \times d \times \rho = 2 \times 10 \times 0\cdot001 \times 8\cdot9\ \text{g}$$
    Energy spent in the process, $W = V\,I\,t$

    But $m = z\,I\,t$ or $I\,t = \dfrac{m}{z}$
    $$\therefore \quad W = \frac{V \times m}{z} = \frac{2 \times 10 \times 0\cdot001 \times 8\cdot9}{0\cdot00033} = 5393\cdot94\ \text{J}$$
12. Let d be thickness of silver deposited.
    Therefore, mass of silver deposited,
    $$m = A\,d\,\rho = 10 \times 10^{-4} \times d \times 10\cdot5 \times 10^{3} = 10\cdot5\,d\ \text{kg}$$
    Now, $m = z\,I\,t$

    or $10\cdot5\,d = 1\cdot118 \times 10^{-6} \times 0\cdot12 \times 48 \times 60 \times 60$

    or $d = 2\cdot2 \times 10^{-3}\ \text{m} = 2\cdot2\ \text{mm}$
13. Now, $\dfrac{m_1}{E_1} = \dfrac{m_2}{E_2}$

    or $$m_2 = m_1 \times \frac{E_2}{E_1} = \frac{1\cdot5 \times 31\cdot5}{1\cdot8} = 0\cdot4375\ \text{g}$$
14. Proceed as in problem no. 13.
15. Proceed as in problem no. 13.
16. Chemical equivalent of copper,
    $$E_1 = \frac{\text{atomic weight}}{\text{valency}} = \frac{63}{2} = 31\cdot5$$
    Chemical equivalent of hydrogen, $E_2 = 1\cdot008$

    E.C.E. of hydrogen, $z_2 = 1\cdot036 \times 10^{-5}$ g C^{-1}

    Therefore, E.C.E. of copper,
    $$z_1 = z_2 \times \frac{E_1}{E_2} = \frac{1\cdot036 \times 10^{-5} \times 31\cdot5}{1\cdot008}$$
    $$= 3\cdot2375 \times 10^{-4}\ \text{g C}^{-1}$$
    Now, $$I = \frac{m_1}{z_1 \times t} = \frac{0\cdot777}{3\cdot2375 \times 10^{-4} \times 30 \times 60} = 1\cdot333\text{A}$$

17. Chemical equivalent of Na,

$$E = \frac{\text{atomic weight}}{\text{valency}} = \frac{23}{1} = 23$$

Now, $F = \frac{E}{z} = \frac{23}{2383 \cdot 4 \times 10^{-7}} = \mathbf{96500\ C}$

18. Now, $z = \frac{E}{F} = \frac{32}{96500} = 3 \cdot 316 \times 10^{-4} \text{g C}^{-1}$

Also, $t = \frac{m}{zI} = \frac{500 \times 10^{-3}}{3 \cdot 316 \times 10^{-4} \times 0 \cdot 15} = 10052 \cdot 3 \text{ s}$

$= \mathbf{167{\cdot}54\ minutes}$

19. $E = \frac{\text{atomic weight}}{\text{valency}} = \frac{108}{1} = 108$

Now, $z = \frac{E}{F} = \frac{108}{96500} = 1 \cdot 12 \times 10^{-3} \text{ g C}^{-1}$

$= 1{\cdot}12 \times 10^{-6} \text{ kg C}^{-1}$

Also, $I = \frac{m}{zt} = \frac{0 \cdot 54}{1 \cdot 12 \times 10^{-6} \times 60 \times 60} = 133 \cdot 93 \text{ A}$

Therefore potential difference to be applied,

$V = IR = 133{\cdot}93 \times 0{\cdot}72 = \mathbf{96{\cdot}4\ mV}$

20. Here, chemical equivalent of oxygen, $E_1 = 8$, chemical equivalent of hydrogen, $E_2 = 1{\cdot}008$ and mass of oxygen deposited, $m_1 = 1$ g

Therefore, mass of hydrogen liberated,

$$m_2 = m_1 \times \frac{E_2}{E_1} = \frac{1 \times 1 \cdot 008}{8} = \mathbf{0{\cdot}126\ g}$$

Now, $z_1 = \frac{E_1}{F} = \frac{8}{96500} = 8 \cdot 29 \times 10^{-5} \text{g C}^{-1}$

$\therefore \quad t = \frac{m_1}{z_1 \times I} = \frac{1}{8 \cdot 29 \times 10^{-5} \times 1} = 12063 \text{ s}$

$= \mathbf{201\ minutes}$

21. (*a*) Now, $z = \frac{m}{It} = \frac{0 \cdot 067}{1 \times 60} = 1 \cdot 1167 \times 10^{-3} \text{g C}^{-1}$

$= \mathbf{1{\cdot}1167 \times 10^{-6}\ kg\ C^{-1}}$

(*b*) Also, $q = \frac{m}{z} = \frac{108 \times 10^{-3}}{1 \cdot 1167 \times 10^{-6}} = \mathbf{9{\cdot}67 \times 10^4\ C}$

(*c*) Since 108 is chemical equivalent of silver, the quantit of charge of $9{\cdot}67 \times 10^4$ C is the value of Faraday constant.

Now, $F = Ne$

Here, $N = 6{\cdot}024 \times 10^{26}$ per kg molecule

$= 6{\cdot}024 \times 10^{23}$ per gram molecule

$\therefore \quad e = \frac{F}{N} = \frac{9 \cdot 67 \times 10^4}{6 \cdot 024 \times 10^{23}} = \mathbf{1{\cdot}6 \times 10^{-19}\ C}$

22. Current passed through voltameter,

$$I = \frac{P}{V} = \frac{100 \times 10^3}{125} = 800 \text{ A}$$

Now, $m = zIt = 0{\cdot}367 \times 10^{-6} \times 800 \times 60 = \mathbf{1{\cdot}762 \times 10^{-2}\ kg}$

23. Charge passing through copper voltameter due t discharge of capacitor,

$$q = \frac{m}{z} = \frac{4 \cdot 62 \times 10^{-6}}{3 \cdot 3 \times 10^{-7}} = 14 \text{ C}$$

Therefore, energy stored in the capacitor before it discharge,

$$U = \frac{1}{2}\frac{q^2}{C} = \frac{14 \times 14}{2 \times 5 \times 10^{-2}} = 1960 \text{ J}$$

When the capacitor discharges, energy stored in th capacitor will generate heat both in series resistance (R) an in the copper voltameter due to its internal resistance (R_{in}

Therefore, heat generated in series resistance R,

$$Q = \frac{U \times R}{R + R_{in}} = \frac{1960 \times 20}{20 + 30} = 784 \text{ J}$$

CHAPTER

5

Thermoelectric Effect

5.01. THERMOELECTRICITY

We know that when electric current is passed through a resistance, electrical energy gets converted into heat energy. This phenomenon is known as ***Joule heating***. If we reverse the direction of flow of current, heat is still produced in the resistance. Thus, Joule heating is an irreversible phenomenon and it cannot be used to convert heat into electrical energy.

Key point

Joule heating is not a reversible effect.

From thermodynamics, we know that heat can be converted into mechanical energy and it led to the development of heat energies. However, heat can be converted into electrical energy by making use of a ***thermocouple***.

A thermocouple is an arrangement of two suitable dissimiliar metallic wires (wires of different materials) joined at their ends to form junctions.

Fig. 5.01. shows a Cu-Fe thermocouple obtained by joining the copper and iron wires at their ends. When one junction of the thermocouple is kept cold and the other hot, a small e.m.f. (≈ a few μV) is developed, which sends current through it. The e.m.f. so produced is called ***thermo-e.m.f.*** and the current so produced is called ***thermo-electric current***. The flow of current can be detected by including a sensitive galvanometer in the thermocouple. The electrical energy is produced at the expense of a net amount of heat absorbed in the thermocouple.

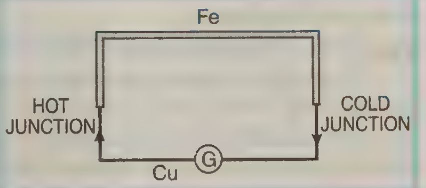

Fig. 5.01

The conversion of heat into electrical energy by using a thermocouple is called thermoelectricity.

Key point

A thermocouple produces thermo-e.m.f. by converting heat into electric energy.

In a Cu-Fe thermocouple, current flows from copper to iron through hot junction as shown in the figure.

5.02. ORIGIN OF THERMO E.M.F.

A conductor always contains free electrons. The number of free electrons per unit volume in a conductor depends upon the nature of its material. Further, the number of free electrons per unit volume, called electron density, increases with rise in temperature.

When two metallic wires of different materials are joined at their ends to form a thermocouple, electrons from a metal having greater electron density diffuse into the other with lower value of electron density. Due to this, a small potential difference is established across the junction of the two metals. The potential difference so established is called contact potential and its value depends upon the temperature of the junction. Obviously, if the two junctions are at the same temperature, the contact potentials at the two junctions will be equal. The equal contact potentials at the two junctions tend to send equal currents but in opposite directions ; and as such no net current flows through the thermocouple.

Self-test Questions

No current flows through a thermocouple, when its two junctions are at the same temperature. Why ?

However, if one of the two junctions is heated, then diffusion of electrons at the hot junction becomes more and likewise the contact potential at the hot junction also becomes more than that at the cold junction. Hence, when the two junctions of a thermocouple are at different temperatures, a net e.m.f., called thermo-e.m.f. is produced.

5.03. SEEBECK EFFECT

The phenomenon of producing thermoelectric e.m.f. (or thermoelectric current) in a thermocouple by keeping its two junctions at different temperatures is called thermoelectric effect.

This effect was discovered by Thomas Johann Seebeck in 1821, which after his name is also known as *Seebeck effect*.

Seebeck effect can be demonstrated with any two dissimilar metals. As said earlier, in a Cu-Fe thermocouple, the current flows from copper to iron through hot junction and from iron to copper through cold junction.

Cause of Seebeck effect. Suppose that a current I flows through the thermocouple, when its two junctions are kept at different temperatures. The two wires used to make the thermocouple and the galvanometer have got some resistance, say R. It implies that an amount of electrical energy $I^2 R$ is being converted into heat every second. It is natural to ask, where is this energy coming from ? Obviously, there must be a source of e.m.f. somewhere in the thermocouple, which is causing the flow of current. Experimental studies showed that a thermocouple constantly absorbs some heat (Q) from the hot junction and rejects a part of it (Q′) to the cold junction. The net amount of heat absorbed (Q – Q′) is converted into electrical energy. Thus, a thermocouple acts like a heat engine and the net heat absorbed (Q – Q′) is the source of e.m.f. in the circuit.

Key point

Seebeck effect is reversible in nature.

It may be pointed out that Seebeck effect, in fact, is the resultant of two effects*, namely ***Peltier effect*** and ***Thomson effect***.

Seebeck effect is reversible. Consider that a cell is put in the circuit so that it sends current in a direction from copper to iron through cold junction *i.e.* in a direction opposite to the direction of flow of current in a Cu-Fe thermocouple as shown in Fig 5.02. It is found that heat is now evolved (liberated) at the hot junction and absorbed at the cold junction. In other words, the hot junction is found to become hotter and the cold junction colder than before. It shows that Seebeck effect is reversible in nature.

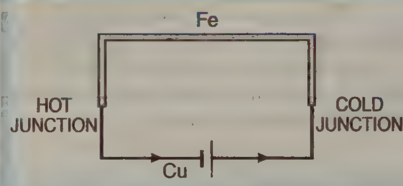

Fig. 5.02

5.04. THERMOELECTRIC SERIES

The magnitude and direction of the thermo-e.m.f. produced in a thermocouple depends upon the nature of the metals forming the thermocouple and to the temperature difference between the two junctions. Keeping this fact in view, Seebeck studied the behaviour of a many pair of metals. On the basis of his experimental results, he arranged a number of metals in the form of series, called ***thermoelectric series.*** Some of the metals forming the series are as below :

Sb, As, Fe, Zn, Ag, Au, Mo, Cr, Sn, Pb, Hg, Mn, Cu, Pt, Co, Ni and *Bi*.

It is also called ***Seebeck series.***

The following are two main uses of the thermoelectric series :

1. *To know direction of current.* If a thermocouple is formed with wires of any two metals from the thermoelectric series, *the direction of current will be from a metal occurring earlier in this series to the metal occurring later in the series through the cold junction.* Therefore, in copper-iron (Cu-Fe) thermocouple, the current will flow from iron to copper through cold junction or from copper to iron through the hot junction. The words **Hot Coffee** serve as an aid to remember the direction of flow of current in copper-iron thermocouple. In antimony-bismuth (Sb-Bi) thermocouple, the current flows from antimony to bismuth through the cold junction. The direction of flow of current can be remembered with the help of letters **ABC,** where A stands for antimony, B for bismuth and C for cold junction.

Key point

The thermoelectric series can be used to know the direction of flow of thermo-electric current in a thermocouple formed of two metals from the series. Further, it helps to choose the metals, so as to obtain large thermo-e.m.f.

2. *To know magnitude of thermo-e.m.f.* If two metals chosen to form the thermocouple are more widely separated in the series, then the thermo-e.m.f. produced (for the same temperature difference between the two junctions of the thermocouple) is also greater. As a rule, *more the metals are separated in the thermoelectric series, greater is the thermo-e.m.f. produced.*

The thermo-e.m.f. produced for a difference of temperature equal to 100°C is about 0·0013 V for Cu-Fe thermocouple and about 0·008 V for Sb-Bi thermocouple.

5.05. VARIATION OF THERMO-E.M.F. WITH TEMPERATURE

The magnitude of thermo-e.m.f. increases, when the temperature of hot junction is increased and the temperature of other junction (cold junction) is kept constant.

To study the effect of difference of temperature between the two junctions, consider a Cu-Fe thermocouple. Its one junction is kept hot by immersing in oil bath, heated with a burner. The other junction is kept cold by immersing it in pounded ice and as shown in Fig. 5.03. The temperature of the hot junction can be measured by the thermometer T placed in the hot oil bath.

As the temperature of the hot junction is increased by keeping the temperature of the cold junction constant at 0°C, the deflection in the galvanometer goes on increasing. The deflection in the galvanometer is directly proportional to the thermoelectric current and hence the thermo-e.m.f. The graph between thermo e.m.f.

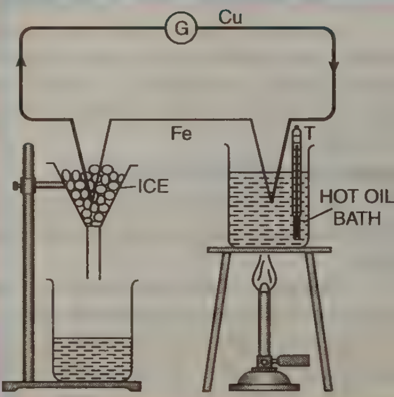

Fig. 5.03

---

*For the discussion of Peltier effect and Thomson effect, refer to sections 5.09 and 5.11.

and the temperature of hot junction is found to be parabolic in shape and is as shown in Fig. 5.04. As the temperature of hot junction is further increased, a stage comes, when the thermo-e.m.f. becomes maximum.

The temperature of hot junction, at which the thermo-e.m.f. produced in the thermocouple becomes maximum, is called **neutral temperature.** *It is denoted by* θ_n.

The value of neutral temperature :

(*i*) *is independent of the temperature of the cold junction of the thermocouple and is always constant for a given thermocouple.*

(*ii*) *depends on the nature of the materials of the two metals used to form the thermocouple.*

For example, whatever may be the temperature of the cold junction, for Cu-Fe thermocouple, neutral temperature is always 270°C.

As the temperature of the hot junction is further increased, the thermo-e.m.f. decreases and ultimately becomes zero. If the temperature of the junction is still increased, direction of the thermo-e.m.f. reverses.

The temperature of the hot junction, at which the direction of the thermo e.m.f. reverses, is called the ***temperature of inversion.*** It is denoted by θ_i.

The value of temperature of inversion :

(*i*) *depends on the temperature of the cold junction of the thermocouple and therefore is not constant for a given thermocouple.*

It is found that *the temperature of inversion is as much above the neutral temperature as the neutral temperature is above the temperature of the cold junction.* Thus, if θ_c is temperature of the cold junction, then

$$\theta_n - \theta_c = \theta_i - \theta_n$$

or

$$\theta_n = \frac{\theta_i + \theta_c}{2} \qquad \text{...(5.01)}$$

Therefore, the neutral temperature is the mean of the temperature of inversion θ_i and temperature of the cold junction θ_c. For Cu-Fe thermocouple $\theta_n = 270°$. If cold junction is at 0°C, then it follows that $\theta_i = 540°C$.

(*ii*) *depends on the nature of the materials of the two metals forming the thermocouple.*

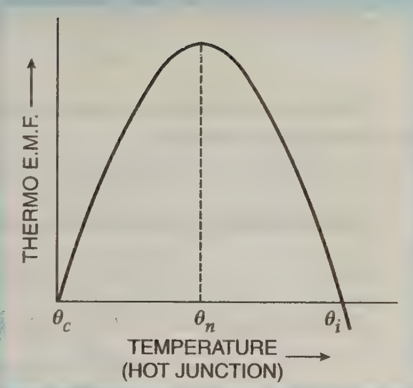

Fig. 5.04

5.6. RELATION BETWEEN THERMO E.M.F. AND TEMPERATURE OF HOT JUNCTION

When cold junction of a thermocouple is kept at 0°C and temperature of hot junction is increased, the graph between the thermo-e.m.f. and the temperature of hot junction is found to be parabolic in nature. Further, for a number of metals, the parabolic graph between thermo-e.m.f. (E) and temperature of hot junction was found to satisfy the simple relation

$$E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2, \qquad \text{...(5.02)}$$

where α and β are constants, called ***thermoelectric constants.*** The value of these constants depend upon the nature of the two metals forming the thermocouple. However, the above relation between E and θ holds over a limited range of temperature.

The following table gives the value of α and β for the thermocouples formed of the various metals with lead. These values of α and β have been found in the temperature range 200 K to 400 K.

Substance	α (μV °C^{-1})	β (μV °C^{-2})
Aluminium	$-0 \cdot 76$	$+0 \cdot 0039$
Bismuth	$-43 \cdot 7$	$-0 \cdot 465$
Copper	$+1 \cdot 34$	$+0 \cdot 0094$
Constantan	$-38 \cdot 1$	$-0 \cdot 089$
Iron	$+17 \cdot 2$	$-0 \cdot 048$
Platinum	$-3 \cdot 04$	$-0 \cdot 033$

Self-test Question

Using equation (5.02), find the units of α and β.

5.07. THERMOELECTRIC POWER

The rate of change of thermo-e.m.f. with the change in the temperature of the hot junction is called thermoelectric power.

Thermoelectric power is also called **Seebeck coefficient** and is denoted by S.

Key point

Thermoelectric power is also called Seebeck coefficient.

Thus, thermoelectric power (or Seebeck coefficient),

$$S = \frac{dE}{d\theta} \qquad ...(5.03)$$

We know that thermo-e.m.f. varies with the temperature of the hot junction according to the relation

$$E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2 \qquad ...(5.04)$$

Differentiating both sides of equation (5.04) w.r.t. θ, we have

$$\frac{dE}{d\theta} = \frac{d}{d\theta}(\alpha\,\theta + \frac{1}{2}\beta\,\theta^2) = \alpha + \beta\,\theta$$

Therefore, equation (5.03) becomes

$$S = \frac{dE}{d\theta} = \alpha + \beta\,\theta \qquad ...(5.05)$$

The equation (5.05) tells that if a graph is plotted between θ (along X-axis) and $dE/d\theta$ (along Y-axis), the graph will be a straight line having slope β and making intercept α on Y-axis. Thus, the graph between $\frac{dE}{d\theta}$ and θ will be as shown in Fig. 5.05.

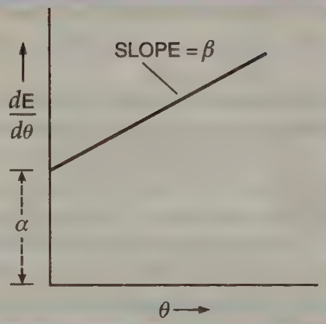

Fig. 5.05

We know that at the neutral temperature of the thermocouple, the thermo-e.m.f. is maximum *i.e.* rate of change of thermo-e.m.f. with temperature becomes zero. Therefore,

when $\qquad \theta = \theta_n, \; \frac{dE}{d\theta} = 0$

Setting the above condition in equation (5.05), we have

$$\alpha + \beta\,\theta_n = 0$$

or $\qquad \theta_n = -\frac{\alpha}{\beta} \qquad ...(5.06)$

It gives the value of neutral temperature of the thermocouple in terms of its thermoelectric constants α and β.

Key point ✓

At neutral temperature of the thermocouple, its seeback coefficient becomes zero.

5.08. SEEBECK EFFECT–A RESULTANT OF TWO EFFECTS

As said earlier, Seebeck effect is a resultant of two effects, called the Peltier effect and the Thomson effect. When the two junctions of a thermocouple are kept at different temperatures, the different parts of the two wires constituting the thermocouple are also at different temperatures. The e.m.f. developed in the thermocouple is partly due to different temperatures of the two junctions and partly due to different temperatures along the length of the two wires of the thermocouple. As explained below, Peltier effect accounts for the e.m.f. developed due to different temperatures of the two junctions, while Thomson effect is responsible for the e.m.f. developed due to different temperatures along the length of the two wires.

Key point ✓

The thermo-e.m.f. due to Seeback effect is resultant of e.m.fs. produced due to Peltier and Thomson effects.

5.09. PELTIER EFFECT

This effect was discovered by the French physicist Jean Charles Peltier in 1834.

Peltier found that when two metals, say bismuth and copper are connected to form a thermocouple, an e.m.f. exists across each of the two junctions of the thermocouple. In case of Bi-Cu thermocouple, copper is at higher potential as compared to bismuth. The e.m.f. across the junction of two metals increases with increase of temperature of the junction Let π_A abd π_B be the e.m.fs. developed due to Peltier effect at the hot and cold junction respectively [Fig. 5.06]. The thermocouple is, thus, equivalent to a circuit containing two sources of e.m.f. π_A and π_B, such that π_A is greater than π_B. Obviously, the resultant e.m.f. of the circuit is $\pi_A - \pi_B$. This resultant e.m.f. causes a current to flow from bismuth to copper at hot junction *i.e.* from a metal at lower potential to the one at higher potential. Since energy is required for current to flow from lower potential to higher potential, heat is absorbed at the hot junction. On the other hand, current flows from copper to bismuth at the cold junction *i.e.* from a metal at higher potential to the metal at lower potential. Hence, energy is evolved at the cold junction.

This absorption or evolution of heat at a junction of two dissimilar metals, when a current is passed, is known as Peltier effect.

Key point ✓

Peltier effect accounts for the e.m.f. developed in the thermocouple due to difference in temperatures of the two junctions of the thermocouple.

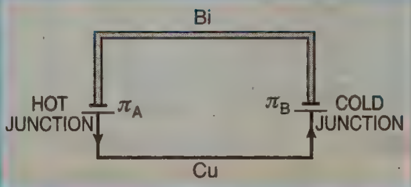

Fig. 5.06

Peltier effect is reversible. If the direction of flow of current is reversed, heat will be evolved at the hot junction and absorbed at the cold junction. Thus, Peltier effect is reversible in nature.

Peltier coefficient. *The amount of heat energy absorbed or evolved per second at a junction, when a unit current is passed through it, is known as Peltier coefficient.* It is denoted by π.

Suppose the cold junction of the thermocouple is at temperature T and hot junction at T+ dT. If dE is the thermo-e.m.f. produced, then it is found that

$$\frac{\pi}{T}=\frac{dE}{dT} \qquad ...(5.07)$$

Here, $\frac{dE}{dT}$ is rate of charge of thermo-e.m.f. As said earlier, it is known as *thermoelectric power* or *Seebeck coefficient* (S). Therefore, equation (5.07) may be written as

$$\frac{\pi}{T}=\frac{dE}{dT}=S \qquad ...(5.08)$$

5.10. DIFFERENCE BETWEEN JOULE HEATING AND PELTIER EFFECT

The following points of difference can be drawn between Peltier effect and Joule heating effect of current :

Peltier effect	Joule heating effect
1. Heat is evolved or absorbed at the junctions of the thermocouple.	1. Heat is evolved throughout the conductor.
2. Heat evolved or absorbed at a junction varies directly as the current passed.	2. Heat evolved in the conductor varies directly as the square of the current passed.
3. If the direction of current is reversed, heat is absorbed at the junction, where earlier heat was evolved and vice-versa.	3. There is no change in Joule effect on reversing the direction of current *i.e.* whatever may be the direction of current, always heat is evolved.
4. Both heating or cooling effect can take place at the same junction of the thermocouple. The effect produced depends upon the direction of flow of current through the junction.	4. It is always a heating effect.
5. The amount of heat evolved or absorbed at a junction depends upon the nature of the two metals forming the thermocouple.	5. It depends upon the resistance of the conductor.

5.11. THOMSON EFFECT

Thomson discovered that when two ends of a conductor are kept at different temperatures, an e.m.f. develops between the two ends. For example, in case of copper wire, the hotter end is at higher potential [Fig. 5.07]. Therefore, when current flows through a copper wire from the hotter to the colder end *i.e.* from end at higher potential to the end at lower potential, heat is evolved along the wire. As a result, the copper wire will get heated. On the other hand, when current flows from the colder to hotter end *i.e.* from lower to higher potential, heat is absorbed along the wire. It will result in cooling of the wire. A few other such metals are antimony, silver, zinc, etc. All other substances, are said to possess ***positive Thomson effect.***

In the case of a bismuth wire, the hotter end is at lower potential as shown in Fig. 5.08. Therefore, when current flows through a bismuth wire from the hotter to the colder end, heat is absorbed along the wire and when current flows from the colder to the hotter end, heat is evolved along the wire. A few other such metals are iron, cobalt, platinum, etc. All such metals, are said to possess ***negative Thomson effect.***

This absorption or evolution of heat along the length of a conductor on passing current through it, when its two ends are kept at different temperatures is known as Thomson effect.

For lead, Thomson effect is zero. Further, Thomson effect is also reversible in nature.

Thomson coefficient. *The amount of heat energy absorbed or evolved per second between two points of a conductor having a unit temperature difference, when a unit current is passed, is known as Thomson coefficient for the material of a conductor.* It is denoted by σ.

Thomson coefficient of the material of a conductor is found by forming its

Key point

Thomson effect accounts for the e.m.f. developed in a thermocouple due different temperatures along the length of each of the two wires forming the thermocouple.

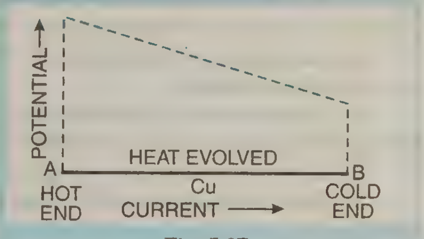

Fig. 5.07

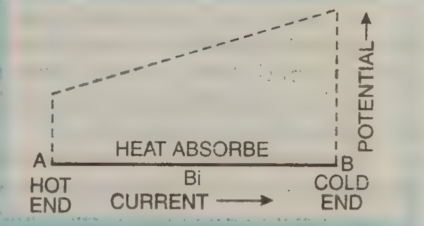

Fig. 5.08

Key point

Thomson effect may be positive, negati
or zero depending on the nature of met

thermocouple with a lead wire (Thomson coefficient of lead is zero). It can be proved that Thomson coefficient of the material of conductor is given by

$$\sigma = -T\frac{d^2E}{dT^2} \qquad ...(5.09)$$

Now, Seebeck coefficient is given by

$$S = \frac{dE}{dT}$$

$$\therefore \qquad \frac{dS}{dT} = \frac{d^2E}{dT^2}$$

Thus,

$$\sigma = -T\frac{d^2E}{dT^2} = -T\left(\frac{dS}{dT}\right) \qquad ...(5.10)$$

5.12. THERMOELECTRIC THERMOMETER (To measure temperature)

It is a device used to measure both low and high temperatures.

Principle. *It is based on Seebeck effect.*

Construction. A thermoelectric thermometer is basically a thermocouple. Two metals used to construct the thermoelectric thermometer are chosen depending upon the range of measurement of temperature as given below :

Thermocouple	Range of temperature
Copper-gold and iron alloy	1 K to 50 K
Copper-constantan	50 K to 400 K
Platinum-platinum and iridium alloy	400 K to 1300 K
Platinum-platinum rhodium alloy	1500 K to 2000 K

The wires to be used for forming the thermocouple are welded together at one end and this end forms the hot junction. The two wires near the hot junction are kept separate from each other by enclosing them in hard glass capilliary tubes (C.T.). The wires, then, pass through mica discs (D), which are arranged one above the other in a porcelain tube T. The ends of the two wires are connected to the terminals T_1 and T_2 fitted on the lid of the porcelain tube. To shift the cold junction to a convenient place, two wires L_1 and L_2 made of same material as those used for making the thermocouple, are connected to the terminals T_1 and T_2 [Fig. 5.09]. The wires L_1 and L_2 are called compensating leads.

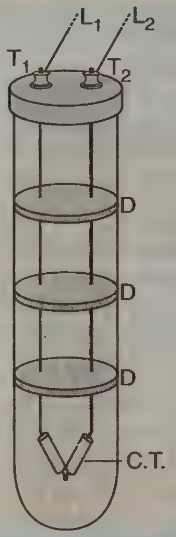

Fig. 5.09

Theory. Before measuring the temperature of an unknown hot body, a graph between thermo-e.m.f. and the temperature of hot junction is plotted, keeping cold junction at 0°C. The graph so obtained is called calibration curve of the thermocouple and it is as shown in Fig. 5.04. Then, to measure the temperature of the hot body, one junction is kept at 0°C and the other junction is placed in contact with the hot body. The thermo-e.m.f. produced in the thermocouple is measured. The temperature of the hot body is read from the calibration curve against the measured thermo-e.m.f. It may be pointed out that instead of plotting calibration curve, the galvanometer or the micro voltmeter included in the thermocouple may be calibrated, so as to directly read the temperature of the hot body.

Advantages. A thermoelectric thermometer has following advantages over mercury thermometer :

1. Thermoelectric thermometers have much wider range of measurement of temperature (from – 200°C to 1600°C).

2. These thermometers are quite cheap and can be easily constructed.

3. They are quite sensitive and can measure temperature accurately up to 0·05C.

4. They can be used to measure the temperature of the specific part of a hot body.

5. Due to the low thermal capacity of the junction of two metals, they attain the temperature of the hot body very quickly. As such, they are found to be useful for measuring rapidly varying temperatures.

6. They form the basis of the radiation pyrometer for measuring temperature of a hot body from a distance.

Disadvantages. 1. These thermometers are not direct reading thermometers and hence they cannot be used in experiments on calorimetery.

2. Each thermoelectric thermometer has to be calibrated separately before using it to measure the temperature.

3. For measurment of temperature over different ranges, different thermoelectric thermometers (thermocouples made of different materials) have to be used.

5.13. THERMOPILE (To detect heat radiation)

It is a device used to detect and measure the intensity of heat radiations. It is based on Seebeck effect.

Key point

When n identical thermocouples are connected in series, thermo-e.m.f. produced by the arrangement is n times the thermo-e.m.f. produced by a single thermo-couple for a given difference between the temperatures of the two junctions.

Principle. For a given small difference in temperature of two junctions of a thermocouple, Bi-Sb thermocouple produces a comparatively large e.m.f. and it can be used to detect the heat radiation. When, a number of such thermocouples are connected in series, the arrangement becomes very much sensitive to detect heat radiation as the thermo-e.m.fs. of the thermocouples get added.

Construction. A series combination of a large number of Bi-Sb thermocouples is enclosed in a funnel or a horn-shaped enclosure.

The junction A of each thermocouple is coated with lamp black, while the junction B of each thermocouple is well polished and covered with insulating material. The extreme ends of the arrangement are connected to the terminals T_1 and T_2, across which a sensitive galvanometer is connected. Such an arrangement forms a thermopile and is as shown in Fig. 5.10.

Working. When heat radiations fall on the funnel shaped end of the thermopile, the set of junctions A coated with lamp black absorb the heat radiation. As a result, the temperature of set of junctions A relative to junctions B rises and thermo-e.m.f. is developed in each thermocouple. The thermoelectric current flows in the same direction (from Sb to Bi through cold junction) in all the thermocouples. Therefore, a large current flowing through the circuit produces deflection in the galvanometer, which in turn detects the heat radiation falling on it.

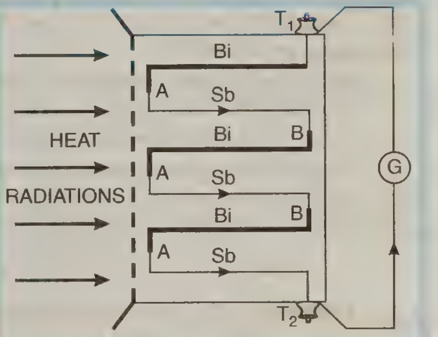

Fig. 5.10

5.14. APPLICATIONS OF THERMOELECTRIC EFFECT

The thermoelectric effect has the following important applications :

1. To measure temperature. A thermocouple is preferred and used to measure temperatures in industries and laboratories for the following reasons :

(*i*) Since the junction is very small, it absorbs only a very small amount of heat and therefore it does not change the temperature of the object.

(*ii*) It quickly attains the temperature of the hot object.

(*iii*) The accuracy in the measurement of temperature is quite high.

2. To detect heat radiation. A thermopile is a combination of a large number of thermocouples in series. It can be used to detect the heat radiation and to note the small difference or the variation in temperatures, if any.

3. Thermoelectric refrigerator. As discussed earlier, if a current is passed through a thermocouple, then due to Peltier effect, heat is removed at one junction and is absorbed at the other junction. In case, if on the whole, heat is removed, then the thermocouple acts as a thermoelectric refrigerator. The advantage is that it has no compressor. No doubt, the cooling effect produced is much low as compared to that in case of a conventional refrigerator. A thermoelectric refrigerator is used, when the region to be cooled is very small and the noise is not acceptable. The thermocouple used as a thermoelectric refrigerator should have following three characteristics :

(*i*) It should have low resistivity. Otherwise, loss of energy in the form of heat will be large.

(*ii*) It should have low thermal conductivity. It will help in maintaining large temperature difference between the two junctions.

(*iii*) It should produce high thermopower.

Researches have shown that these requisites are met best by the semiconductor $Bi_2 Te_3$.

4. Thermoelectric generator. Thermocouples can be used to generate thermoelectric power in remote areas. It may be done by heating one junction in a flame and exposing the other junction to air. The thermo-e.m.f. developed has been used to power radio receivers, etc.

SOLVED NUMERICAL PROBLEMS

Type A. On Neutral temperature and Temperature of inversion

Problem 5.01. In a given thermocouple, the temperature of cold junction is 15 °C, while the neutral temperature is 270 °C. What is the value of the temperature of inversion ?

Sol. Here, temperature of cold junction, $\theta_c = 15\ °C$;

neutral temperature, $\theta_n = 270°C$

If θ_i is temperature of inversion, then

$$\theta_i = 2\,\theta_n - \theta_c = 2 \times 270 - 15 = 540 - 15 = \mathbf{525\ °C}$$

Problem 5.02. The cold junction of a thermocouple is kept at 10 °C. Calculate the temperature at which thermo-e.m.f. would be maximum. Given that the thermo-e.m.f. changes sign at 800 K.

Sol. Here, temperature of cold junction, $\theta_c = 10°C$

Thermo-e.m.f. changes sign at temperature of inversion.

$$\therefore \qquad \theta_i = 800\ K = 800 - 273 = 527\ °C$$

When the temperature of the hot junction is equal to neutral temperature for thermocouple, thermo-e.m.f. produced is maximum. The neutral temperature is given by

$$\theta_n = \frac{\theta_i + \theta_c}{2} = \frac{527 + 10}{2} = \mathbf{268 \cdot 5\ °C}$$

Problem 5.03. Near room temperature, the thermo-e.m.f. of copper-constantan thermocouple is 40 μV °C^{-1} at room temperature. What is the smallest temperature difference that can be detected with single such thermocouple and a galvanometer of 100 ohm resistance capable of detecting currents as low as 10^{-6} ampere ?

Sol. Resistance of galvanometer $= 100\ \Omega$

Least current that can be detected $= 10^{-6}$ A

Therefore, least e.m.f. that can be detected

$$= 100 \times 10^{-6} = 10^{-4}\ V$$

e.m.f. developed per °C in the thermocouple

$$= 40\ \mu V = 40 \times 10^{-6}\ V$$

Therefore, least temperature that can be detected

$$= \frac{10^{-4}}{40 \times 10^{-6}} = \mathbf{2 \cdot 5\ °C}$$

Type B. On Thermo-e.m.f.

Problem 5.04. Calculate the thermo-e.m.f. of a silve iron thermocouple with junction at 0 °C and 80 °C. Give that $\alpha = +\ 13 \cdot 31\ \mu V\ °C^{-1}$ and $\beta = 0 \cdot 038\ \mu V\ °C^{-2}$. Als calculate the neutral temperature. *(Karnataka 198*

Sol. If θ is temperature difference between the cold an hot junction of a thermocouple, then thermo-e.m.f. is give by

$$E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2$$

Here, $\theta = 80 - 0 = 80°C$; $\alpha = +\ 13 \cdot 31\ \mu V\ °C^{-1}$;

$\beta = -\ 0 \cdot 038\ \mu V\ °C^{-2}$;

$$\therefore \qquad E = 13 \cdot 31 \times 80 + \frac{1}{2}(-\ 0 \cdot 038) \times 80^2 = \mathbf{943 \cdot 2\ \mu V}$$

Also, neutral temperature,

$$\theta_n = -\frac{\alpha}{\beta} = -\frac{13 \cdot 31}{(-\ 0 \cdot 038)} = \mathbf{350 \cdot 26\ °C}$$

TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 5.05. The e.m.f. E of a Cu-Fe thermocouple varies with the temperature θ of the hot junction (cold junction at 0 °C) as

$$\mathbf{E\ (\mu V) = 14\ \theta\ -\ 0 \cdot 02\ \theta^2}$$

Determine the neutral temperature.

(H.S.S.C.E. 2001 ; C.B.S.E. 1990)

Sol. Here, the thermo-e.m.f. of thermocouple at temperature θ of hot junction,

$$E\ (\mu V) = 14\ \theta\ -\ 0 \cdot 02\ \theta^2 \qquad ...(i)$$

The expression for thermo-e.m.f. is given by

$$E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2 \qquad ...(ii)$$

Comparing the equations (*i*) and (*ii*), we have

$$\alpha = 14\ \mu V\ °C^{-1}\ ;\ \beta = -\ 0 \cdot 04\ \mu V\ °C^{-2}$$

Now, neutral temperature,

$$\theta_n = -\frac{\alpha}{\beta} = -\frac{14}{-\ 0 \cdot 04} = \mathbf{350°\ C}$$

Aliter. Here, $E = 14\ \theta - 0 \cdot 02\ \theta^2$ ...(*i*)

The thermo-e.m.f. is maximum at neutral temperature. In other words,

$$\text{when} \qquad \theta = \theta_n, \quad \frac{dE}{d\theta} = 0 \qquad ...(ii)$$

Differentiating the equation (*i*) *w.r.t.* θ, we have

$$\frac{dE}{d\theta} = 14 - 0 \cdot 02 \times 2\,\theta = 14 - 0 \cdot 04\,\theta$$

Applying the condition given by equation (*ii*), we have

$$0 = 14 - 0 \cdot 04\ \theta_n \quad \text{or} \quad \theta_n = 14 / 0 \cdot 04 = \mathbf{350°\ C}$$

Problem 5.06. The thermoelectric e.m.f. E of a copp constantan thermocouple and the temperature θ of th hot junction (with cold junction at 0°C) are found to satisf approximately the following relation :

$$\mathbf{E = \alpha\,\theta + \beta\,\theta^2}$$

where E is in μV, θ in °C. Also, $\alpha = 41\ \mu V\ °C^{-1}$ and $\beta = 0 \cdot 04$ $\mu V\ °C^{-2}$. What is the temperature of the hot junction, whe the thermo-electric e.m.f. is measured to be 5·5 mV ?

(Text Problen

Sol. The thermo-e.m.f. of the thermocouple at tempe rature θ of the hot junction is given by

$$E = \alpha\,\theta + \beta\,\theta^2 \qquad ...($$

Here, $E = 5 \cdot 5\ mV = 500\ \mu V$;

$\alpha = 41\ \mu V\ °C^{-1}$ and $\beta = 0 \cdot 041\ \mu V\ °C^{-2}$

Therefore, equation (*i*) becomes

$$5500 = 41\ \theta + 0 \cdot 041\ \theta^2$$

$$\text{or} \qquad 0 \cdot 041\ \theta^2 + 41\ \theta - 5500 = 0$$

$$\text{or} \qquad \theta = \frac{-\ 41 \pm \sqrt{(41)^2 - 4 \times 0 \cdot 041 \times (-5500)}}{2 \times 0 \cdot 041}$$

$$= \frac{-\ 41 \pm \sqrt{1681 + 902}}{0 \cdot 082} = \frac{-\ 41 \pm 50 \cdot 82}{0 \cdot 082}$$

Since the temperature of hot junction has to be greate than 0°C, it follows that

$$\theta = \frac{-\ 41 + 50 \cdot 82}{0 \cdot 082} = \mathbf{119 \cdot 76\ °C}$$

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 5.01. Give the direction in which thermoelectric current flows at the hot junction of a Cu-Fe thermocouple. (*C.B.S.E. 2001*)

Ans. From Cu to Fe.

Q. 5.02. Give the direction of thermoelectric current (*i*) at the cold junction of Cu-Bi (*ii*) at the hot junction of Fe-Cu (*iii*) at the cold junction of platinum-lead thermocouple.

Ans. (*i*) From Cu to Bi. (*ii*) From Cu to Fe. (*iii*) From lead to platinum.

Q. 5.03. Give any two factors on which thermoelectric e.m.f. produced in a thermocouple depends. (*C.B.S.E. 1997*)

Ans. Thermo- e.m.f. produced in a thermocouple depends upon (*i*) the temperature of hot junction and (*ii*) the nature of the two metals forming the thermocouple.

Q. 5.04. How does the thermo-e.m.f. vary with the temperature of the hot junction ? (*H.S.S.C.E. 2001*)

Ans. The thermo-e.m.f. increases with increase in temperature of hot junction, till the temperature becomes equal to the neutral temperature for the thermocouple. As the temperature is increased beyond the neutral temperature, thermo-e.m.f. starts decreasing.

Q. 5.05. Draw a graph showing the variation of thermo-e.m.f. with temperature, indicating the position of neutral temperature and temperature of inversion. (*I.S.C.E. 1994*)

Ans. For the graph, refer to Fig. 5.04.

The temperature corresponding to the peak of the graph is neutral temperature (θ_n) and the temperature, corresponding to which, the thermo e.m.f. reverses sign, is temperature of inversion (θ_i).

Q. 5.06. What is the nature of the plot between thermo-e.m.f. and the temperature of hot junction ?

Ans. It is parabolic in nature.

Q. 5.07. Define neutral temperature of a thermocouple. (*P.S.S.C.E. 2002*)

Ans. *The temperature of the hot junction, at which the thermo-e.m.f. produced in the thermo-couple becomes maximum, is called neutral temperature.*

Q. 5.08 How does the neutral temperature of a thermocouple vary with the temperature of the cold junction ? (*C.B.S.E. 2001*)

Ans. The neutral temperature of a thermocouple does not vary with the temperature of the cold junction.

Q. 5.09. Is the neutral temperature for a thermocouple constant ?.

Ans. Yes, the neutral temperature for a thermocouple is a constant.

Q. 5.10. Is the temperature of inversion for a thermocouple constant ?

Ans. No, the temperature of inversion for a thermocouple is not a constant.

Q. 5.11. Write the expression connecting the thermoelectric e.m.f. of a thermocouple with the temperature difference of its cold and hot junctions. (*H.S.S.C.E. 1999 ; C.B.S.E. 1995*)

Ans. The relation between thermo-e.m.f (E) and temperature difference (θ) between the cold and the hot junction is given as

$$E = \alpha\theta + \frac{1}{2}\beta\theta^2$$

Q. 5.12. What are the units of α and β in relation to thermoelectricity ?

Ans. The unit of α is μV °C^{-1} and that of β is μV °C^{-2}.

Q. 5.13. Define Seebeck coefficient. (*P.S.S.C.E. 2001*)

Ans. *The rate of change of thermo-e.m.f. with the change in temperature of the hot junction of a thermocouple is called Seebeck coefficient.*

It is also known as thermoelectric power.

Q 5.14. What is the value of Seebeck coefficient at the neutral temperature of a thermocouple ? (*C.B.S.E. 2002*)

Ans. It is zero.

Q. 5.15. What is Peltier effect ? (*P.S.S.C.E. 2001*)

Ans. Refer to section 5.09.

Q. 5.16. Define Peltier coefficient. (*P.S.S.C.E. 2001*)

Ans. *The amount of heat energy absorbed or evolved per second at a junction, when a unit current is passed through it, is known as Peltier coefficient of the junction*

Q. 5.17. What is Thomson effect ? (*P.S.S.C.E. 2001*)

Ans. Refer to section 5.11.

Q. 5.18. Define Themsom coefficient.(*P.S.S.C.E. 2001*)

Ans. *The amount of heat energy absorbed or evolved per second between two points of a conductor having a unit temperature difference, when a unit current is passed, is known as Thomson coefficient for the material of the conductor.*

Q. 5.19. Give one practical application of thermoelectricity. (*C.B.S.E. 1991*)

Ans. Thermoelectric effect is used to measure temperature and to detect heat radiation.

Q. 5.20. What is a thermopile ?

Ans. It is a combination of a large number of thermocouples in series. As such, for a small temperature difference between its hot and cold junctions, comparatively a large e.m.f. is produced. It can be used to detect the heat radiation and to note the small variation or difference in temperature.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 5.01. What is thermo-e.m.f. ? Explain its origin. (*P.S.S.C.E. 2002, 1999 S*)

Ans. Thermo e.m.f. *The e.m.f. produced in a thermocouple, when its two junctions are kept at different temperatures, is called thermo-e.m.f.*

Origin of thermo e.m.f. Refer to section 5.02.

Q. 5.02. Briefly explain the origin of thermo-e.m.f. (*H.S.S.C.E. 2001*)

Ans. Refer to section 5.02.

Q. 5.03. What is Seebeck effect ? Give one example. (*P.S.S.C.E. 2000 ; C.B.S.E. 1990*)

Ans. Seebeck effect. *The phenomenon of production of an electric current in a thermocouple, when its two junctions are kept at different temperatures, is known as Seebeck effect.*

For example, when a thermocouple is formed of the two wires of copper and iron, the current flows from copper to iron through hot junction.

Q. 5.04. What is Seebeck effect ? On what factors, magnitude of thermo-e.m.f. depends ? (*H.S.S.C.E. 2001*)

Ans. Seebeck effect. Refer to section 5.02.

The magnitude of thermo e.m.f. depends upon the difference in the temperature between the two junctions and the nature of metals used to form a thermocouple. The thermo-e.m.f. produed increases, when the two metals chosen to form the thermocouple are widely separated in the thermoelectric series.

Q. 5.05. How does thermoelectric series help to predict the direction of flow of current in a thermocouple ?

Ans. It helps to know the direction in which current will flow, when a thermocouple is formed with the wires of any two metals in the series. The direction of current will be from a metal occurring earlier in this series to the metal occurring later in the series through the cold junction.

Q. 5.06. Why do we generally prefer Sb-Bi thermocouple ? (*H.P.S.S.C.E. 1999 S, 1999*)

Ans. The metals Sb and Bi are at the two extreme ends of the thermoelectric series and hence for the given temperatures of cold and hot junctions, the thermo-e.m.f. produced is maximum. It is because, more the metals are separated in the series, the greater is the thermo-e.m.f. produced.

Q. 5.07. What is thermo-e.m.f. ? Show its variation with temperature by a graph. (*P.S.S.C.E. 1997*)

Ans. *The e.m.f. developed in a thermocouple when its tw junctions are maintained at different temperature, is called therm e.m.f.*

For the graph, refer to Fig. 5.04.

Q. 5.08. Plot a graph showing variation of thermo electric e.m.f. with temperature of hot junction. Defin neutral temperature. (*H.S.S.C.E. 200*

Ans. For graph, refer to Fig. 5.04.

Neutral temperature. Refer to VSQ 5.07.

Q. 5.09. Define temperature of inversion. State tw factors on which the temperature of inversion of a thermo couple depends. (*C.B.S.E. 2000, 1998 S*

Ans. Temperature of inversion. Refer to section 5.05.

The temperature of inversion of a thermocoupl depends upon the temperature of cold junction and the natur of the metals forming the thermocouple.

Q. 5.10. Define thermoelectric power. What is it magni-tude at neutral temperature ?

(*C.B.S.E. 2000 ; H.S.S.C.E. 1998 S*

Ans. For definition, refer to section 5.07.

At neutral temperature, thermoelectric power is **zero**

Q. 5.11. State and explain Seebeck effect. Mention it one application. (*C.B.S.E. 199*

Ans. For seebeck effect, refer to section 5.03.

A thermopile is based on Seebeck effect. It is used t detect heat radiation or to detect any small variation i temperature.

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 5.01 A sensitive microphone cannot withstand currents greater than 0·05 A. When connected across a thermocouple of e.m.f. 8·5 mV, the current in a very low resistance ammeter placed in series in the circuit reads 34 mA. What is the resistance of the microphone ?

(*Text Question*)

Ans. Here, $E = 8{\cdot}5 \text{ mV} = 8{\cdot}5 \times 10^{-3}$ V

Current passing through the microphone,

$$I = 34 \text{ mA} = 34 \times 10^{-3} \text{ A}$$

Therefore, resistance of the microphone,

$$R = \frac{E}{I} = \frac{8{\cdot}5 \times 10^{-3}}{34 \times 10^{-3}} = 0{\cdot}25\,\Omega$$

Q. 5.02. What is the importance of the relation

$$E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2 \text{ ?}$$

Ans. From the relation ; $E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2$, we have

$$\frac{dE}{d\theta} = \alpha + \beta\,\theta \qquad ...(i)$$

When the temperature of the hot junction is equal to neutral temperature, thermo-e.m.f. is maximum *i.e.* the rate of change of thermo-e.m.f. becomes zero.

Therefore, when $\theta - \theta_n$, $\quad \frac{dE}{d\theta} = 0$

Applying the above condition, the equation (*i*) become

$$\alpha + \beta\,\theta_n = 0 \qquad \text{or} \qquad \theta_n = -\frac{\alpha}{\beta}$$

Therefore, knowing the values of the constants α and for a thermocouple, neutral temperature of the thermo-coupl can be found.

Q. 5.03. Heat is produced at a junction of two metals when a current passes through. When the direction o current is reversed, heat is absorbed at the junction (*i.e.* th junction gets cooler). Is the usual formula ($I^2 R$ =powe dissipated as heat) applicable for this situation ? If no why not ?

Ans. This phenomenon of absorption of heat at a junctio on reversing the direction of current is known as Peltier effec The formula describing Joule's heating effect of current is no applicable to Peltier effect. The reason is that heat absorbe or evolved at a junction is directly proportional to the curren passing through the thermocouple. Further, Peltier effect i reversible, whereas Joule's heating effect is not reversible i nature.

6. Discuss the effect of temperature on thermo-e.m.f. of a thermocouple. *(P.S.S.C.E. 1998 S)*
7. Explain neutral temperature and temperature of inversion. Establish a relation between them. *(H.P.S.S.C.E. 1998, P.S.S.C.E. 1997 S)*
8. Explain the terms thermo-emf, neutral temperature and temperature of inversion. *(P.S.S.C.E. 1994)*
9. What is Seebeck effect ? Give a mathematical relationship between e.m.f. E and the temperature of the hot junction θ, while the other junction is kept at 0°C. *(I.S.C.E. 1997, 1993)*
10. The thermo-e.m.f. of a thermocouple is given by

$$E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2,$$

where θ is the temperature of the hot junction ; α and β are the constants of the thermocouple. Deduce an expression for the neutral temperature. *(C.B.S.E. 2000, 1998 S)*

11. What is Seebeck effect ? Explain its cause. How thermoelectric power changes with temperature and hence find neutral temperature ? *(H.P.S.S.C.E., 1995)*
12. (*a*) Explain neutral temperature and temperature of inversion. Establish a relation between them. *(H.S.S.C.E. 2002)*

    (*b*) How is thermocouple used for measuring temperature ?
13. What is Peltier effect and Peltier coefficient ? How is Peltier coefficient related to thermoelectric power ?
14. What is the difference between Joule's heating effect and Peltier effect ? *(H.P.S.S.C.E. 1997)*
15. What is Thomson effect and Thomson coefficient ? How is Thomson coefficient related to thermo-e.m.f. and Seebeck coefficient ?
16. How is a thermocouple used for measuring unknown temperature ? Give the advantages and disadvantages of using thermocouple as a temperature measuring device.
17. Explain a few important practical applications of thermoelectric effect.

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. (*a*) What is Seebeck effect ? How does the e.m.f. of a thermocouple vary with temperature of the hot junction ? (*b*) Explain the terms neutral temperature and temperature of inversion in the case of thermocouple. *(Pre-degree Kerala, 1994)*
2. What is a thermocouple ? Which of the two thermocouples Sb-Bi or Cu-Fe produces greater e.m.f. for the same temperature difference between hot and cold junctions ? Graphically sketch the variation of thermo e.m.f. generated as a function of temperature of the hot junction keeping the cold junction at 0°C. Give two applications of thermocouples. *(C.B.S.E. 1999 S)*

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Neutral temperature and Temperature of inversion

1. The neutral temperature of Cu-Fe thermocouple is 270 °C. If the temperature of the cold junction is 20 °C, what will be the temperature of inversion ? [**Ans.** 520 °C]
2. The e.m.f. of a thermocouple changes sign at 700 K. If the neutral temperature is 210 °C, what is the temperature of cold junction ? [**Ans.** 7 °C]

Type B. On Thermo-e.m.f.

3. Calculate the thermo-e.m.f. of silver-iron thermocouple with junctions at 20°C and 80°C.

   Given that $\alpha = +\,13{\cdot}3\ \mu\text{V}\ {}^\circ\text{C}^{-1}$ and $\beta = -\,0{\cdot}019\ \mu\text{V}\ {}^\circ\text{C}^{-2}$. *(Karnataka, 1985)* [**Ans.** 763·8 μV]
4. For a Cu-Fe thermocouple, neutral temperature is 270 °C. If $\alpha = 15{\cdot}86\ \mu\text{V}\ {}^\circ\text{C}^{-1}$, then find the value of β. [**Ans.** – 0·0587 $\mu\text{V}\ {}^\circ\text{C}^{-2}$]
5. The e.m.f. of a copper-iron thermocouple varies with the temperature of hot junction as

$$E\ (\text{in } \mu\text{V}) = 11\,\theta - 0{\cdot}02\,\theta^2$$

   Determine the neutral temperature, if the cold junction is maintained at 0°C. *(H.S.S.C.E. 2002)* [**Ans.** 275 °C]
6. The thermo-e.m.f. of a thermocouple is given by the expression $E = \alpha\,\theta - \beta\,\theta^2$, where θ is the temperature of the hot junction. If $\alpha = 42\ \mu\text{V}\ {}^\circ\text{C}^{-1}$, $\beta = 0{\cdot}035\ \mu\text{V}\ {}^\circ\text{C}^{-2}$, calculate the (*i*) neutral temperature and (*ii*) temperature of inversion of the thermocouple, if the cold junction is at 20°C. *(C.B.S.E. 2001)* [**Ans.** (*i*) 600 °C (*ii*) 1180 °C]
7. The thermo-e.m.f. of a thermocouple varies with the temperature of a hot junction according to the relation $E = 14\,\theta - 0{\cdot}02\,\theta^2$, where θ is the temperature af the hot junction. Calculate : (*i*) neutral temperature of the thermocouple, (*ii*) temperature of inversion, assuming that cold junction is at 20°C and (*iii*) value of Seebeck coefficient at neutral temperature. *(C.B.S.E. 2002)* [**Ans.** (*i*) 350°C (*ii*) 680 °C (*iii*) 0]
8. For a copper-iron and a chromel-alumel thermocouple, the plots between thermo-e.m.f. and the temperature of the hot junction (when the cold junction is at 0°C) are found to satisfy approximately the equation $E\ (\text{in } \mu\text{V}) = \alpha\,\theta + \beta\,\theta^2$, where for copper-iron : $\alpha = 11\ \mu\text{V}\ {}^\circ\text{C}^{-1}, \beta = -\,0{\cdot}02\ \mu\text{V}\ {}^\circ\text{C}^{-2}$ and for chromel-alumel : $\alpha = 41\ \mu\text{V}\ {}^\circ\text{C}^{-1}, \beta = -\,0{\cdot}03\ \mu\text{V}\ {}^\circ\text{C}^{-2}$ Which of the two thermocouples, would you use to measure temperature in the range of about 500° to 600°C. [**Ans.** Chromel-alumel]
9. The thermo-e.m.f. of copper-constantan thermocouple is $50\ \mu\text{V}\ {}^\circ\text{C}^{-1}$ at room temperature. A galvanometer of resistance 50 Ω and capable of detecting currents of the order of 2 μA is used. Calculate the smallest temperature difference that can be detected with this galvanometer. [**Ans.** 2°C]

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Now, $\theta_i - \theta_n = \theta_n - \theta_c$

   or $\theta_i = 2\,\theta_n - \theta_c = 2 \times 270 - 20 = \mathbf{520\ °C}$

2. Proceed as in solved problem no. 5.01.

3. Here, $\alpha = 13{\cdot}3\ \mu\text{V °C}^{-1}$; $\beta = -\,0{\cdot}019\ \mu\text{V °C}^{-2}$

   and $\theta = 80 - 20 = 60$°C

   Now, $E = \alpha\,\theta + \frac{1}{2}\,\beta\,\theta^2 = 13{\cdot}3 \times 60 + \frac{1}{2} \times (-\,0{\cdot}019) \times (60)^2$

   $= 798 - 34{\cdot}2 = \mathbf{763{\cdot}8\ \mu V}$

4. Now, $\theta_n = -\dfrac{\alpha}{\beta}$

   or $\beta = -\dfrac{\alpha}{\theta_n} = -\dfrac{15{\cdot}86}{270} = \mathbf{-\,0{\cdot}0587\ \mu V\ °C^{-2}}$

5. Here, $E = 11\,\theta - 0{\cdot}02\,\theta^2$ ...(*i*)

   But $E = \alpha\,\theta + \frac{1}{2}\,\beta\,\theta^2$ ...(*ii*)

   Comparing equations (*i*) and (*ii*), we have

   $\alpha = 11\ \mu\text{V °C}^{-1}$ and $\beta = -\,0{\cdot}02 \times 2 = -\,0{\cdot}04\ \mu\text{V °C}^{-2}$

   Now, $\theta_n = -\dfrac{\alpha}{\beta} = \dfrac{11}{-\,0{\cdot}04} = \mathbf{275\ °C}$

6. Here, $E = \alpha\,\theta - \beta\,\theta^2$

   (*i*) Now, $\dfrac{dE}{d\theta} = \dfrac{d}{d\theta}(\alpha\,\theta - \beta\,\theta)^2 = \alpha - 2\,\beta\,\theta$

   When $\theta = \theta_n$, $\dfrac{dE}{d\theta} = 0$

   $\therefore$ $0 = \alpha - 2\,\beta\,\theta_n$ or $\theta_n = \dfrac{\alpha}{2\,\beta}$

   or $\theta_n = \dfrac{42}{2 \times 0{\cdot}035} = \mathbf{600\ °C}$

   (*ii*) $\theta_i = 2\,\theta_n - \theta_c = 2 \times 600 - 20 = \mathbf{1180\ °C}$

7. Proceed as in problem no. 6.

   (*iii*) Seebeck coefficient, $S = \dfrac{dE}{d\theta}$

   At neutral temperature, $\dfrac{dE}{d\theta} = 0$

   Therefore, at neutral temperature,

   $$S = 0$$

8. A thermocouple can be used to measure temperature in the range 500°C to 600°C, if neutral temperature for the thermocouple is fairly above the range of temperature measurement.

   Here, $E = \alpha\,\theta + \beta\,\theta^2$

   $\therefore$ $\dfrac{dE}{d\theta} = \dfrac{d}{d\theta}(\alpha\,\theta + \beta\,\theta^2) = \alpha + 2\,\beta\,\theta$

   When $\theta = \theta_n$, $\dfrac{dE}{d\theta} = 0$

   $\therefore$ $0 = \alpha + 2\,\beta\,\theta_n$ or $\theta_n = -\dfrac{\alpha}{2\,\beta}$

   For copper-iron thermocouple :

   $$\theta_n = -\frac{\alpha}{2\,\beta} = -\frac{11}{2 \times (-0{\cdot}02)} = 275\,°\text{C}$$

   For chromel-alumel thermocouple :

   $$\theta_n = -\frac{\alpha}{2\,\beta} = -\frac{41}{2 \times (-0{\cdot}03)} = 683{\cdot}33\,°\text{C}$$

   Therefore, **chromel-alumel thermocouple** can be used to measure temperature in the range 500°C to 600°C.

9. Resistance of galvanometer, $G = 50\ \Omega$

   The minimum current that can be detected by the galvanometer,

   $$I_{min} = 2\ \mu A$$

   Therefore, minimum e.m.f. that can be detected by the galvanometer,

   $$E_{min} = I_{min} \times G = 2 \times 50 = 100\ \mu V$$

   For a difference of temperature of 1°C, copper-constantan thermocouple produces thermo-e.m.f. of 50 μV.

   Therefore, smallest temperature that can be detected by the galvanometer,

   $$\theta = \frac{100}{50} = 2\ °\text{C}$$

Competitive Examination File (Unit II)

REVISION AT A GLANCE

Chapter 1. Electric current, Resistance and E.M.F.

☐ **Electric current.** *It is the rate of flow of electric charge through a conductor.*

Mathematically : $I = \frac{dq}{dt}$

Unit. In SI, the unit of electric current is **ampere (A).**

1 ampere (A) = 1 coulomb second^{-1} (C s^{-1})

☐ **Ohm's law.** It states that *physical conditions remaining unchanged, the current flowing through a conductor is always directly roportional to the potential difference across its two ends.*

Mathematically : $V \propto I$ or $V = RI$

Here, R is called resistance of the conductor.

Unit. The unit of resistance is **ohm (Ω)**

1 ohm (Ω) = 1 volt ampere^{-1} (V A^{-1})

☐ **Resistance of a conductor.** The resistance of a conductor of length l and area of cross-section A is given by

$$R = \rho \frac{l}{A}$$

Here, ρ is ***resistivity*** of the material of the conductor.

☐ **Resistivity.** *The resistivity of the material of a conductor is the resistance offered by a wire of this material of unit length and nit area of cross-section.* It is also known as ***specific resistance*** of the material of the wire.

Unit. The SI unit of resistivity is **ohm metre (Ω m)**

☐ **Conductance.** *The reciprocal of the resistance of a conductor is called its conductance* (G). Thus,

$$G = \frac{1}{R}$$

Unit. The SI unit of conductance is **ohm^{-1} (Ω^{-1})** or **siemen** (S). ohm^{-1} is also written as **mho.**

☐ **Conductivity.** *The reciprocal of the resistivity of the material of a conductor is called its conductivity* (σ). Thus,

$$\sigma = \frac{1}{\rho}$$

Unit. The SI unit of conductivity is **ohm^{-1} metre^{-1} (Ω^{-1} m^{-1})** or **siemen metre^{-1} (S m^{-1}).** ohm^{-1} metre^{-1} is also written s **mho metre^{-1}.**

☐ **Drift velocity.** *It is the velocity with which a free electron in the conductor gets drifted under the influence of the applied external lectric field.*

Mathematically : $v_d = \frac{eE}{m}\tau = \frac{I}{nAe}$

Here, τ is average relaxation time and n is number of free electrons per unit volume in the conductor. The other symbols ave their usual meanings.

☐ **Temperature coefficient of resistance.** *It is defined as the change in resistance per unit resistance per degree rise in temperature.*

If resistance increases linearly up to temperature θ, then temperature coefficient,

$$\alpha = \frac{R_\theta - R_0}{R_0 \times \theta}$$

Unit. The unit of temperature coefficient is **°C^{-1}.**

☐ **Thermistor.** *A thermally sensitive resistance is called a thermistor.*

☐ **Resistors in series.** The total resistance of resistors R_1, R_2 and R_3 in series is given by

$$R_s = R_1 + R_2 + R_3$$

☐ **Resistors in parallel.** The total resistance of resistors R_1, R_2 and R_3 in parallel is given by

$$\frac{1}{R_p} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}$$

☐ **E.M.F.** *The work done per unit charge by the source in taking the charge from its one terminal to the other is called the electromotive orce or e.m.f. of the source.*

It is equal to potential difference between the two terminals of the source, when no current is drawn from it.

☐ **Internal resistance.** *The resistance offered by the electrolyte of the cell, when the electric current flows through it is known as nternal resistance of the cell.*

If V is potential difference across the two terminals of a cell, when a current I is drawn from it, then

$$V = E - Ir = E\left(1 - \frac{r}{R+r}\right) \qquad \left(\because I = \frac{E}{R+r}\right.$$

Here, E is e.m.f. of the cell and R is the external resistance in the circuit.

Mathematically : Internal resistance, $r = \left(\frac{E}{V} - 1\right)R$

Some Useful Facts :

1. $6{\cdot}25 \times 10^{18}$ electrons passing through a conductor per second constitute a current of one ampere.

2. In most of the substances, the carriers of electric current are electrons. In electrolytes and ionic crystals, the curren carriers are positive and negative ions.

3. The resistivity of a material is inversely proportional to the number of electrons per unit volume. It is also inversel proportional to the average relaxation time.

4. The resistivity of metals is in the range $10^{-8}\ \Omega$ m to $10^{-6}\ \Omega$ m. The resistivity of the insulators, such as glass and rubbe is in the range of $10^{10}\ \Omega$ m to $10^{14}\ \Omega$ m. The resistivity of semiconductors lies between that of metals and insulators.

5. The materials used for making standard resistances should have very small temperature coefficient and a high valu of resistivity.

6. Resistors are connected in series, when the resistance in the circuit is to be increased. When the resistors are connecte in series, same current passes through all the resistors.

7. Resistors are connected in parallel, when the resistance in the circuit is to be decreased. When the resistors are connecte in parallel, potential difference across all the resistors is same.

8. Electromotive force is not a force.

9. The cells are connected in series, when the external resistance of the circuit is very large as compared to the total intern resistance of the cells.

10. The cells are connected in parallel, when the external resistance of the circuit is very small as compared to the tot internal resistance of the cells.

Chapter 2. Electrical measurements

☐ **Kirchhoff's Laws.** These laws are used to analyse electric circuits.

First law. *It states that the algebraic sum of the currents meeting at a point in an electrical circuit is always zero.*

Second law. *It states that in any closed part of an electrical circuit, the algebraic sum of the e.m.fs. is equal to the algebraic sum the products of the resistances and the currents flowing through them.*

☐ **Potentiometer.** It is a device used to compare e.m.fs. of two sources or to measure internal resistance of the sourc

Principle. *When a constant current is passed through a wire of uniform area of cross-section, the potential drop across any portio of the wire is directly proportional to the length of that portion.*

☐ **Wheatstone bridge.** It is an arrangement of four resistances used to determine an unknown resistance.

In a balanced Wheatstone bridge,

$$\frac{P}{Q} = \frac{R}{X}.$$

where P, Q, R and X are resistances in four arms of the wheatstone bridge.

☐ **Slide wire bridge.** It is a device used to measure unknown resistance and it is based on the principle of Wheatston bridge. It is also called ***metre bridge.***

Some Useful Facts

1. Kirchhoff's first law and second law are also known as ***junction rule*** and ***loop rule*** respectively.

2. In steady state, the branch of the circuit containing a capacitor acts as an open circuit.

3. In steady state, the inductor acts as a conductor having no resistance.

4. When current I flows through a cell of e.m.f. E and internal resistance r, the potential difference across its two termina is given by

(*a*) $V = E - Ir$, if the current flows *out of* the cell.

(*b*) $V = E + Ir$, if the current flows *into* the cell.

In former case, the potential drop across internal resistance ***opposes*** the e.m.f., whereas in the latter case, it ***aids*** the e.m.

Chapter 3. Thermal effects of current

☐ **Cause of heating effect of current.** The potential difference applied across the two ends of conductor sets up electr field. Under the effect of electric field, electrons accelerate and as they move, they collide against the ions and atoms in th conductor. The energy of electrons transferred to the atoms and ions in the conductor appears as heat.

☐ **Electric power.** *The rate of dissipation of electrical energy in an electric circuit is called electric power.*

Mathematically : $P = VI = \frac{V^2}{R} = I^2 R$

Unit. In SI, the unit of electric power is **watt (W).**

The electric power of a circuit is said to be one watt, if one ampere of current flows through it, when a constant potential difference f one volt is applied across it.

The bigger unit is **kilowatt (kW)** and **megawatt (MW).**

$$\mathbf{1\ kW = 10^3\ W} \quad \text{and} \quad \mathbf{1\ MW = 10^6\ W}$$

☐ **Electric energy.** The total amount of electric energy consumed by an electric circuit depends upon its electric power nd the time for which the circuit is kept on.

Mathematically : $W = P \times t = VIt = \frac{V^2}{R}t = I^2 Rt$

In SI, the unit of electric energy is **joule (J)** but the practical unit of electric energy is **kilowatt hour (kWh).** It is also nown as **Board Of Trade unit (B.O.T.).**

$$W \text{ (in kWh)} = \frac{V \text{ (in volt)} \times I \text{ (in ampere)} \times t \text{ (in hour)}}{1000}$$

Also, $\mathbf{1\ kWh = 3{\cdot}6 \times 10^6\ J}$

Some Useful Facts

1. The heat produced in a conductor on passage of current does not depend upon the direction of flow of current.

2. The fuse wire for an electric circuit is chosen keeping in view the value of safe current through the circuit. The material of fuse wire should have high resistivity and low melting point. However, the melting point of the material of fuse wire should e above the temperature that will be reached on the passage of the safe current through the circuit.

3. The material of the filament of a heater should have high resistivity and high melting point.

Chapter 4. Chemical effects of current

☐ **Electrolysis.** *The process of dissociation of a liquid into ions on passing current through it is called electrolysis.*

☐ **Electrolyte.** *The liquids (or solutions) which allow current through them by dissociating into ions are called electrolytes.*

☐ **Ion.** *An atom, a group of atom or radical having charge is called ion.*

The ions are of two types namely ***cations*** and ***anions***.

Cations are the positive ions and collect at cathode during electrolysis.

Anions are the negative ions and collect at anode during electrolysis.

☐ **Voltameter.** *A vessel containing two electrodes and the electrolyte for carrying out electrolysis is called voltameter.*

☐ **Faraday's first law of electrolysis.** *The mass of substance deposited at the cathode during electrolysis is directly proportional to the total charge passing through the electrolyte.*

Mathematically : $m = zq = zIt$

Here, z is called ***electrochemical equivalent*** of the substance.

☐ **Faraday's second law of electrolysis.** *If same quantity of electricity is passed through different electrolytes, mass of the different substances deposited at the respective cathodes are proportional to their chemical equivalents.*

Mathematically : $\frac{m}{E} = \text{constant}$

Here, E is chemical equivalent (ratio of atomic mass to the valency) of the substance.

For given two substances of chemical equivalents E_1 and E_2, we have

$$\frac{m_1}{m_2} = \frac{E_1}{E_2} = \frac{z_1}{z_2},$$

where letters have their usual meanings.

☐ **Electrochemical equivalent of a substance.** *It is defined as the mass of ions deposited at the cathode, when one coulomb of charge passes through the electrolyte.*

The practical unit of electrochemical equivalent of a substance is **gram coulomb^{-1} (g C^{-1}).**

☐ **Faraday constant.** *It is the quantity of charge required to liberate one gram equivalent of the substance.*

1 faraday (F) = 96500 C mol^{-1}

It has a fixed value.

☐ **Electrochemical cell.** *An arrangement in which chemical reaction can be carried out at a steady rate so as to convert chemical energy into electrical energy is called an electrochemical cell.*

☐ **Primary cell.** *An electrochemical cell which cannot be recharged but the chemicals have to be replaced is called a primary cell.*

☐ **Secondary cell.** *An electrochemical cell in which the chemicals of the cell can be recharged again and again is called a secon cell.*

☐ **Storage capacity of a cell.** *It is the ability of a cell to supply electrical energy.*

Unit. It is measured in **ampere hour (A h).**

Storage capacity of a cell is called one ampere hour, if it can supply one ampere of current for one hour.

Some Useful Facts

1. Usually a liquid is not a conductor of electricity. However, mercury is conductor of electricity and it does not dissoc into ions on passage of electricity through it.

2. Water molecule is polar in nature *i.e.* it possesses permanent electric dipole moment. Further, water molecules h tendency to dissociate. Because of these two facts, water is highly polarizable medium and it has a large value of dielec constant ($K \approx 80$).

3. The crystalline NaCl consists of NA^+ and Cl^- ions. The two ions are held together due to electrostatic force of attract When NaCl is dissolved in water, the electrostatic force of attraction between Na^+ and Cl^- ions is reduced by a factor o (equal to dielectric constant of water). Due to thermal agitation at room temperature, the NaCl molecules in the solutio NaCl, dissociate into free Na^+ and Cl^- ions.

4. (a) *Electrolysis of $CuSO_4$* :

At the cathode : $Cu^{++} + 2e^- \longrightarrow Cu$

At the anode : $Cu \longrightarrow Cu^{++} + 2e^-$

(b) *Electrolysis of $AgNO_3$* :

At the cathode : $Ag^+ + e^- \longrightarrow Ag$

At the anode : $Ag \longrightarrow Ag^+ + e^-$

(c) *Electrolysis of water* :

At the cathode : $4\,H_2O + 4\,e^- \longrightarrow 4\,OH^- + 2\,H_2$

At the anode : $2\,H_2O \longrightarrow 4\,H^+ + 4\,e^- + O_2$

$4\,H^+ + 4\,OH^- \longrightarrow 4\,H_2O$

The net reaction : $2H_2O \longrightarrow 2\,H_2 + O_2$

5. Faraday's second law suggests a relation between electric charge and valency. It leads to the conclusion that the an elementary unit of charge e, which is common to all substances so that all the charges are integral multiples of e.

6. Chemical equivalent, $E = \dfrac{M}{p}$, where M is atomic mass and p is valency of the substance.

7. The total charge required to deposit mass of a substance equal to its atomic mass is equal to Npe, where N is Avoga number and p is valency. Thus,

$$M = z\,(N\,p\,e) \qquad \text{or} \qquad z = \frac{M}{N\,p\,e}$$

8. Faraday constant, $F = N\,e$

9. Electrochemical equivalent of a substance, $z = \dfrac{E}{F}$

10. Faraday's first law may be mathematically expressed as

$$m = \frac{M}{N\,p\,e}\,I\,t = \frac{E}{F}\,I\,t$$

11. Leclanche cell is used in experiments, where constant supply of electric current is not needed. It is because, as cell is used, hydrogen gas causes polarisation of the carbon rod and its e.m.f. falls. But when it is used in experiments requi intermittent current, hydrogen gas escapes (when the cell is not in use) and the cell regains its original e.m.f.

12. A storage cell should not be short circuited. It is because ; during short circuiting, a large current flows through cell and a non-porus layer of $PbSO_4$ is formed. This layer does not decompose during subsequent recharging and the becomes useless.

13. A series resistance is put, while charging a storage cell. It is done so that the cell may not get damaged due to he charging current.

Chapter 5. Thermoelectric effect

☐ **Thermocouple.** *The arrangement of two wires of different materials joined at their ends so as to form junctions is call thermocouple.*

☐ **Seebeck effect.** *The phenomenon of production of e.m.f. causing a current to flow in a thermocouple, when its two junct are kept at different temperatures, is known as Seebeck effect.*

☐ **Thermoelectric series.** The metals forming the thermoelectric series are :

Sb, As, Fe, Zn, Ag, Au, Mo, Cr, Sn, Pb, Hg, Mn, Cu, Pt, Co, Ni and Bi.

1. If a thermocouple is formed of wires of any two metals from the above series, the direction of current is from a metal occurring earlier in the series to the metal occurring latter in the series.

2. More the two metals (used for forming a thermocouple) are separated in the series, the greater is the thermo- e.m.f. produced in the thermocouple.

☐ **Neutral temperature.** *The temperature of the hot junction, at which the thermo-e.m.f. produced in the thermocouple becomes maximum, is called neutral temperature* θ_n.

For a given thermocouple, it is a fixed temperature.

☐ **Temperature of inversion.** *The temperature of the hot junction, at which the thermo e.m.f. reverses its direction, is called temperature of inversion* θ_i.

For a given thermocouple, it changes with temperature of the cold junction (θ_c).

However, *the temperature of inversion is as much above the neutral temperature, as the neutral temperature is above the temperature of the cold junction.*

Mathematically : $\theta_n = \dfrac{\theta_i + \theta_c}{2}$

☐ **Thermoelectric power.** *The rate of change at thermo-e.m.f. with the change in temperature of the hot junction is called thermoelectric power.*

Mathematically : Thermoelectric power $= \dfrac{dE}{d\theta}$

☐ **Laws of Thermoelectricity.** The following two laws have been established experimentally :

1. Law of intermediate metals. *It states that if a number of metals are put between two metals so as to form a chain, then the effective thermo-e.m.f. between the two extreme metals is equal to the sum of the e.m.fs. between intermediate metals, provided all the junctions are at the same temperature.*

Mathematically : If a metal B is put between two metals A and C, then

$$E_A^C = E_A^B + E_B^C$$

2. Law of intermediate temperatures. *It states that the thermo-e.m.f. for a green thermocouple having its junctions at temperatures* θ_1 *and* θ_n *is equal to the sum of the e.m.fs. of the thermocouples of the same metals with junctions at temperatures* θ_1 *and* θ_2 ; θ_2 *and* θ_3 ; θ_3 *and* θ_4 ; .... θ_{n-1} *and* θ_n.

Mathematically : $E_{\theta_1}^{\theta_n} = E_{\theta_1}^{\theta_2} + E_{\theta_2}^{\theta_3} + E_{\theta_3}^{\theta_4} + \ldots\ldots\ldots + E_{\theta_{n-1}}^{\theta_n}$

☐ **Peltier effect.** *The absorption or evolution of heat at a junction of two dissimilar metals, when current is passed, is known as Peltier effect.*

☐ **Peltier coefficient.** *It is defined as the amount of heat energy absorbed or evolved per second at a junction, when a unit current is passed through it.*

☐ **Thomson effect.** *The absorption or evolution of heat along the length of a conductor, when current is passed through the conductor, whose one end is hot and other is kept cold, is known as Thomson effect.*

☐ **Thomson coefficient.** *It is defined as the amount of heat energy absorbed or evolved per second between two points of a conductor having a unit temperature difference, when a unit current is passed, through it.*

☐ **Thermopile.** *An arrangement of a large number of thermocouples connected in series is called a thermopile.*

Some Useful Facts

1. Seebeck effect is reversible in nature. If current is passed through a thermocouple in a direction opposite to the direction of flow of current in the thermocouple, then heat is evolved at the hot junction and absorbed at the cold junction.

2. For given temperatures of cold and hot junctions, Sb-Bi thermocouple produces maximum thermo-e.m.f. It is because, Sb and Bi are the most separated metals in the thermoelectric series.

3. The graph between thermo-e.m.f. (E) and the temperature (θ) of the hot junction is parabolic in nature and is found to satisfy the equation

$$E = \alpha\,\theta + \frac{1}{2}\beta\,\theta^2,$$

4. At neutral temperature, theromo-e.m.f. is maximum *i.e.* $\dfrac{dE}{d\theta} = 0$

It leads to the relation,

$$\theta_n = -\frac{\alpha}{\beta}$$

5. Thermoelectric power is also called ***Seeback coefficient.***

7. Peltier effect and Thomson effect are also reversible in nature.

NUMERICAL PROBLEMS FROM COMPETITIVE EXAMINATIONS

Chapter 1. Electric current, Resistance and E.M.F.

Problem 1.01. A hollow copper tube of 1 metre length has got external diameter equal to 10 cm and its walls are 5 mm thick. Find its resistance if the specific resistance of copper is $1{\cdot}7 \times 10^{-8}\ \Omega$ m. *(I.S.M. Dhanbad, 1982)*

Sol. Here, $l = 1$ m ; $\rho = 1{\cdot}7 \times 10^{-8}\ \Omega$ m

External radius of hollow tube,

$$r_2 = \frac{10}{2} = 5 \text{ cm} = 0{\cdot}5 = 0{\cdot}05 \text{ m}$$

Internal radius of hollow tube, $r_1 = r_2 -$ thickness of tube

Since thickness of tube is 5 mm *i.e.* 0·005 m ;

$$r_1 = 0{\cdot}005 - 0{\cdot}005 = 0{\cdot}045 \text{ m}$$

Area of cross-section of the tube

$$= \pi\left(r_2^2 - r_1^2\right) = \pi\left(0{\cdot}05^2 - 0{\cdot}045^2\right)$$

The resistance of copper tube,

$$R = \rho = \frac{l}{A} = 1{\cdot}7 \times 10^{-8} \times \frac{1}{\pi\,(0{\cdot}05^2 - 0{\cdot}045^2)}$$

$$= \mathbf{1{\cdot}031 \times 10^{-5}\ \Omega}$$

Problem 1.02. If a copper wire is stretched to make it 0·1% longer, what is the percentage change in its resistance ? *(M.N.R. 1990 ; I.I.T. 1978)*

Sol. Let the initial length of the wire be l_1 and its area of cross-section be A_1. If ρ is resistivity of the material of the wire, then

initial resistance of the wire, $R_1 = \rho \dfrac{l_1}{A_1}$

On stretching the wire, the increased length of the wire,

$$l_2 = l_1 \times \frac{100{\cdot}1}{100}$$

If A_2 is the new area of cross-section, then final resistance of the wire, $R_2 = \rho \dfrac{l_2}{A_2}$

Since volume of the wire remains same, $l_1 A_1 = l_2 A_2$

$$\therefore\ R_2 = \rho \frac{l_2}{l_1 A_1 / l_2} = \rho \frac{l_2^2}{l_1 A_1}$$

Substituting for l_2, we have

$$R_2 = \rho \frac{(l_1 \times 100{\cdot}1)^2}{(100)^2 \times l_1 A_1} = 1{\cdot}002 \times \rho \frac{l_1}{A_1} = 1{\cdot}002\, R_1$$

Therefore, % increase in resistance, $\dfrac{R_2 - R_1}{R_1} \times 100$

$$= \frac{1{\cdot}002\, R_1 - R_1}{R_1} \times 100$$

$$= (1{\cdot}002 - 1) \times 100 = 0{\cdot}2\%$$

Problem 1.03. A resistance is made by joining two wires of the same material. The radii of the two wires are 1 mm and 3 mm respectively, while their lengths are 3 cm and 5 cm respectively. A battery of e.m.f. 16 V and negligible internal resistance is connected across the resistance. What is the potential drop along the shorter wire ? *(I.I.T. 1970)*

Sol. In Fig. 1.01, AB and BC are two wires of same material connected to a battery of e.m.f. E = 16 V.

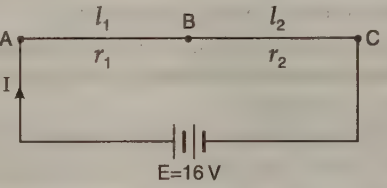

Fig. 1.01

Let ρ be resistivity of the materials of the two wires. If R_1 and R_2 are the resistances of two wires, then

$$R_1 = \rho \frac{l_1}{A_1} = \rho \frac{l_1}{\pi r_1^2}\ ; \text{ and } R_2 = \rho \frac{l_2}{\pi r_2^2}$$

Here, $l_1 = 3$ cm $= 3 \times 10^{-2}$ m, $l_2 = 5$ cm $= 5 \times 10^{-2}$ m, $r_1 = 1$ mm $= 10^{-3}$ m ; $r_2 = 3$ mm $= 3 \times 10^{-3}$ m

$$\therefore\quad R_2 = \rho \frac{3 \times 10^{-2}}{\pi \times (10^{-3})^2} = \frac{3\rho}{\pi} \times 10^{-4}\ ;$$

$$R_2 = \rho \frac{5 \times 10^{-2}}{\pi \times (3 \times 10^{-3})^2} = \frac{5\rho}{9\pi} \times 10^{-4}$$

Total resistance of wire AC, $R = R_1 + R_2$

$$= \frac{3\rho}{\pi} \times 10^4 + \frac{5\rho}{9\pi} \times 10^4 = \frac{32\rho}{9\pi} \times 10^4$$

If I is current through the circuit, then

$$I = \frac{E}{R} = \frac{16 \times 9\pi}{32\rho \times 10^4} = \frac{9\pi}{2\rho} \times 10^{-4}$$

Therefore, potential difference across shorter wire,

$$I R_1 = \frac{9\pi}{2\rho} \times 10^{-4} \times \frac{3\rho}{\pi} \times 10^{-4} = \mathbf{13{\cdot}5\ V}$$

Problem 1.04. An electric current of 5 A is divided into 3 parallel branches, in which the lengths of wire are in the ratio 2 : 3 : 4 and the diameters 3 : 4 : 5. Find the currents in each branch, if the wires are of the same material. *(I.I.T. 1975)*

Sol. Let the lengths of the wires in three branches be $2l$, $3l$ and $4l$ respectively and their diameter be 3 D, 4 D and 5 D respectively [Fig. 1.02].

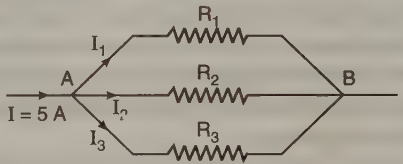

Fig. 1.02.

If ρ is resistivity of the material of the three wires, then

$$R_1 = \rho \frac{2l}{\pi\,(3D)^2/4} = \frac{8\pi l}{9\pi D^2}$$

$$R_2 = \rho \frac{2l}{\pi\,(4D)^2/4} = \frac{3\pi l}{4\pi D^2}$$

and $$R_3 = \rho \frac{4l}{\pi\,(5D)^2/4} = \frac{16\pi l}{25\pi D^2}$$

Let I_1, I_2 and I_3 be the currents through the three ranches as shown in Fig. 2.02. Then,

$$I_1 + I_2 + I_3 = 5 \qquad \ldots(i)$$

As the three wires are connected between the same two oints A and B, we have

$$I_1 R_1 = I_2 R_2 = I_3 R_3 = V \text{ (say)}$$

Then, $I_1 = \dfrac{V}{R_1} = \dfrac{9\pi D^2 V}{16\rho l}$; $I_2 = \dfrac{V}{R_2} = \dfrac{4\pi D^2 V}{3\rho l}$

and $I_3 = \dfrac{V}{R_3} = \dfrac{25\pi D^2 V}{16\rho l}$

Substituting for I_1, I_2 and I_3 in equation (*i*), we have

$$\frac{9\pi D^2 V}{8\rho l} + \frac{4\pi D^2 V}{3\rho l} + \frac{25\pi D^2 V}{16\rho l} = 5$$

or $$\frac{\pi D^2 V}{\rho l}\left(\frac{9}{8} + \frac{4}{3} + \frac{25}{16}\right) = 5$$

or $$\frac{\pi D^2 V}{\rho l} \times \frac{193}{48} = 5$$

or $$\frac{\pi D^2 V}{\rho l} = \frac{240}{193}$$

$\therefore$ $$I_1 = \frac{9\pi D^2 V}{8\rho l} = \frac{9}{8} \times \frac{240}{193} = \mathbf{1{\cdot}40\ A},$$

$$I_2 = \frac{4\pi D^2 V}{3\rho l} = \frac{4}{3} \times \frac{240}{193} = \mathbf{1658\ A}$$

and $$I_3 = \frac{25\pi D^2 V}{16\rho l} = \frac{25}{16} \times \frac{240}{193} = \mathbf{1{\cdot}943\ A}$$

Problem 1.05. The resistances of the four sides of a uare ABCD are 10 Ω, 5 Ω, 7 Ω and 2 Ω in that order. A sistance of 10 Ω is connected in between A and C. alculate the equivalent resistance between A and B. *(I.S.M. Dhanbad, 1984)*

Sol. The given resistances are connected as shown in Fig. 03.

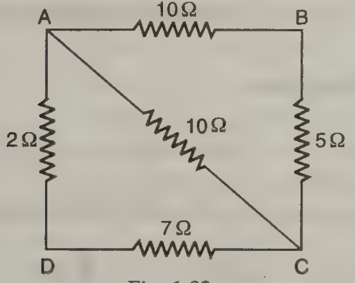

Fig. 1.03

Consider the part ADC of the network of the resistances. follows that the resistances AD and DC are connected in ries. Therefore, their effective resistance,

$$R_1 = 2 + 7 = 9\ \Omega$$

The resistance of path ADC and resistance AC are in rallel. Therefore, their effective resistance,

$$R_2 = \frac{R_1 \times 100}{R_1 + 10} = \frac{9 \times 10}{9 + 10} = \frac{90}{19}\ \Omega$$

The effective resistance R_2 of part ADC and resistance BC are in series. Therefore, their effective resistance,

$$R_3 = R_2 + 5 = \frac{90}{19} + 5 = \frac{185}{19}\ \Omega$$

The effective resistance R_3 and resistance AB are in parallel. Therefore, equivalent resistance of the network,

$$R = \frac{R_3 \times 10}{R_3 + 10} = \frac{\frac{185}{19} \times 10}{\frac{185}{19} + 10} = \mathbf{4{\cdot}933\ \Omega}$$

Problem 1.06. Calculate the steady state current in the 2 Ω resistor shown in the circuit in Fig. 1.04. The internal resistance of the battery is negligible and the capacitance of the capacitor C is 0·2 microfarad. *(I.I.T. 1982)*

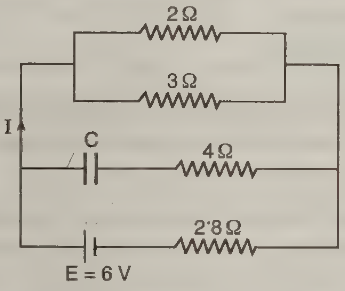

Fig. 1.04

Thought Process

In steady state, a capacitor offers infinite resistance to d.c. and it acts as open path.

Sol. The effective resistance of the parallel combination of 2 Ω and 3 Ω resistors is given by

$$R' = \frac{2 \times 3}{2 + 3} = 1{\cdot}2\ \Omega$$

Since capacitor offers infinite resistance to d.c., it acts as open path. Therefore, current cannot flow through the branch containing the capacitor and the 4 Ω resistance and hence the given network may be redrawn as shown in Fig. 1.05.

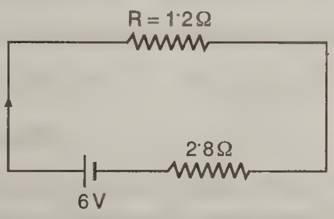

Fig. 1.05

Therefore, total resistance of the circuit,

$$R = R' + 2{\cdot}8 = 1{\cdot}2 + 2{\cdot}8 = 4\ \Omega$$

Current drawn from the cell, $I = \dfrac{E}{R} = \dfrac{6}{4} 1{\cdot}5\ A$

Potential difference across R′(the parallel combination of 2 Ω and 3 Ω resistance),

$$V = I R' = 1{\cdot}5 \times 1{\cdot}2 = 1{\cdot}8\ V$$

Therefore, current through 2 Ω resistor

$$= \frac{V}{2} = \frac{1{\cdot}8}{2} = 0{\cdot}9\ A$$

Problem 1.07. An infinite ladder network of resistances is constricted with 1 Ω and 2 Ω resistances as

shown in Fig. 2.06. The 6 V battery between A and B has negligible internal resistance.

(*a*) Show that the effective resistance between A and B is 2 Ω.

(*b*) What is the current that passes through the 2 Ω resistance nearest to the battery ? (*Roorkee 1989 ; I.I.T. 1987*)

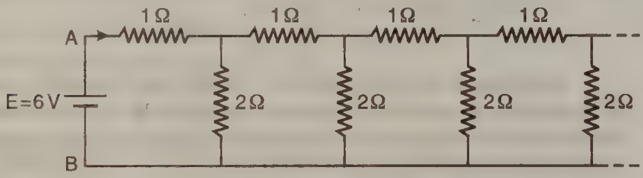

Fig. 1.06

Thought Process

As the network of resistances is infinite, adding one more set of the resistances of 1 Ω and 2 Ω will not affect the total resistance of the network.

Sol. (*a*) Let the equivalent resistance of the infinite ladder network of the resistances be X. Since the network is infinite, adding one more set of resistances of 1 Ω and 2 Ω across the terminals A and B will not affect the total resistance X of the network. The network on adding one set of two resistances of 1 Ω and 2 Ω will appear as shown in Fig. 1.07.

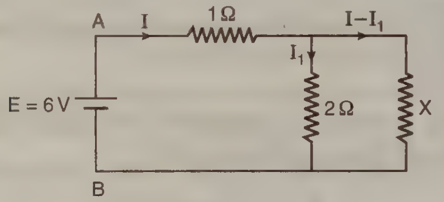

Fig. 1.07

Now, total resistance across A and B

= 1 + resistance equivalent to the parallel combination of 2 Ω and X

$$= 1 + \frac{2\,X}{2+X}$$

Since total resistance of the network remains unaffected,

$$1 + \frac{2\,X}{2+X} = X \qquad \text{or} \qquad X_2 - X - 2 = 0$$

or $\qquad X = -1\,\Omega \qquad$ or $\qquad 2\,\Omega$

Since X cannot be equal to – 1 Ω, we have

$$X = 2\,\Omega$$

(*b*) If I is current from the battery, then

$$I = \frac{E}{X} = \frac{6}{2} = 3\text{ A}$$

Suppose a part I_1 of the current flows throug resistance and the remaining part $(I - I_1)$ passes thro resistance X. Then,

$$2 \times I_1 = (I - I_1)\,X \text{ or } 2 \times I_1 = (3 - I_1) \times 2$$

or $\qquad I_1 = 1{\cdot}5$ A

Problem 1.08. 12 cells each having the same e.m. connected in series and are kept in a closed box. Some c cells are wrongly connected. This battery is connect series with an ammeter and two cells identical wit others. The current is 3 A , when the cells and batter each other and 2 A, when the cells and battery oppose other. How many cells in the battery are wrongly connec

(*Roorkee, 1993 ; I.I.T.*

Sol. Let e.m.f. of each cell be E. If *n* cells out of 1 wrongly connected, then (12–*n*) cells will send current i direction, while *n* cells in opposite direction. Therefore

net e.m.f. of the battery=$(12-n)\,E - n\,E = (12 - 2$

When the two cells aid the battery :

Then, total e.m.f. of the circuit = $(12 - 2\,n)\,E + 2$

Let R be the resistance of the circuit. Then,

$$\text{current in the circuit, } \frac{(12-2\,n)\,E + 2\,E}{R} = 3$$

When the two cells oppose the battery :

Total e.m.f. of the circuit = $(12 - 2\,n)\,E - 2\,E$

$$\text{Then, current in the circuit, } \frac{(12-2\,n)\,E - 2\,E}{R} = 2$$

Dividing equation (*i*) by (*ii*), we have

$$\frac{(12-2\,n)\,E+2\,E}{(12-2\,n)\,E-2\,E} = \frac{3}{2} \text{ or } \frac{(12-2\,n)+2}{(12-2\,n)-2} = \frac{3}{2}$$

Solving for *n*, we get

$$n = 1$$

Hence, **one cell has been wrongly connected.**

Chapter 2. Electrical Measurements

Problem 2.01. Three resistors are joined to form a triangle ABC, such that AB = 1 Ω, BC = 2 Ω and CA = 3 Ω. A cell of e.m.f. 3 V and internal resistance 1 Ω is connected to points A and C. Determine the current in the three arms and also the potential difference at the cell terminals.

(*I.S.M. Dhanbad, 1986*)

Sol. The three resistors of 1Ω, 2 Ω and 3 Ω are connected to form a triangle ABC as shown in Fig. 2.01.

The cell of e.m.f. E = 2 V and internal resistance *r* = 1 Ω are connected across points A and C. Since resistance of path ABC is 1 + 2 *i.e.* 3 Ω, it easily follows that the resistance of the triangular net work ABC,

$$R = \frac{3 \times 3}{3+3} = 1{\cdot}5\,\Omega$$

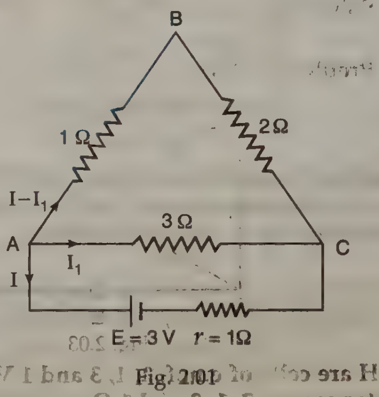

Fig. 2.01

If I is current from the cell, then

$$I = \frac{E}{R + r} = \frac{3}{1{\cdot}5 + 1} = 1{\cdot}2\ A$$

Suppose that part I_1 of the current flows through arm AC, so that part $(I - I_1)$ flows along the path ABC. Obviously,

$I_1 \times$ resistance of path AC

$= (I - I_1) \times$ resistance of path ABC

or $\quad I_1 \times 3 = (1{\cdot}2 - I_1) \times 3$

or $\quad I_1 = 0{\cdot}6\ A$

Therefore, current through arm AC, $I = 0{\cdot}6\ A$

Also, the current through the arms AB and BC,

$$I - I_1 = 1{\cdot}2 - 0{\cdot}6 = 0{\cdot}6\ A$$

Potential difference at the cell terminals,

$$V = E - I r = 3 - 1{\cdot}2 \times 1 = 1{\cdot}8\ V$$

Problem 2.02. A 10 V battery having an internal resistance of 1 Ω is joined in parallel with another of 20 V and internal resistance 2 Ω. The combination is placed across an external resistance of 30 Ω. Apply Kirchhoff's laws, find the current flowing through each battery.

(I.S.M. Dhanbad, 1993)

Sol. The given two batteries of e.m.fs. $E_1 = 10$ V and $E_2 = 20$ V are connected in parallel to an external resistance R = 30 Ω as shown in Fig. 2.02. Their internal resistances are $r_1 = 1 Ω$ and $r_2 = 2\ Ω$ respectively. Let I_1 and I_2 be currents due to the batteries E_1 and E_2 respectively.

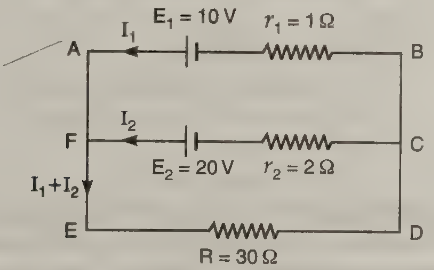

Fig. 2.02.

For the closed part ABDEA :

$$E_1 = I_1 r_1 + (I_1 + I_2) R$$

or $\quad 10 = I_1 \times 1 + (I_1 + I_2) \times 30$

or $\quad 31\ I_1 + 30\ I_2 = 10 \qquad ...(i)$

For the closed part CDEFC :

$$E_2 = I_2 r_2 + (I_1 + I_2) R$$

or $\quad 10 = I_2 \times 2 + (I_1 + I_2) \times 30$

or $\quad 15\ I_1 + 16\ I_2 = 10 \qquad ...(ii)$

Solving equations (*i*) and (*ii*), we have

$$I_1 = -\,3{\cdot}043\ A,\ I_2 = 3{\cdot}478\ A$$

Problem 2.03. In the circuit shown in Fig. 2.03, E, F, G and H are cells of e.m.f. 2, 1, 3 and 1 V and their internal resistances are 2, 1, 3 and 1 Ω respectively. Calculate (*a*) the potential difference between B and D and (*b*) the potential difference across the terminals of each of the cells G and H.

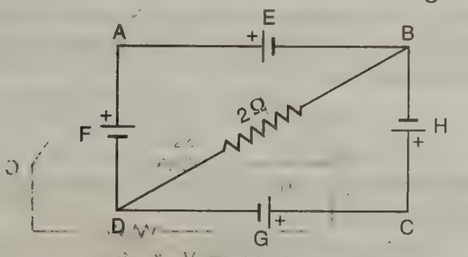

Fig. 2.03

(I.I.T. 1984)

Thought Process

In a circuit, when the current flows through a cell from its positive to negative terminal, the potential difference across its internal resistance aids the e.m.f. of the cell. On the other hand, when the current flows from its negative to positive terminal, the potential difference across its internal resistance opposes the e.m.f. of the cell.

Sol. Let E_1, E_2, E_3 and E_4 be e.m.fs. and r_1, r_2, r_3 and r_4 be internal resistances of the four cells E, F, G and H respectively.

The given circuit can be redrawn after incorporating the internal resistances of the cells as shown in Fig. 2.04. The distribution of currents in various branches of the circuit has also been shown in the figure.

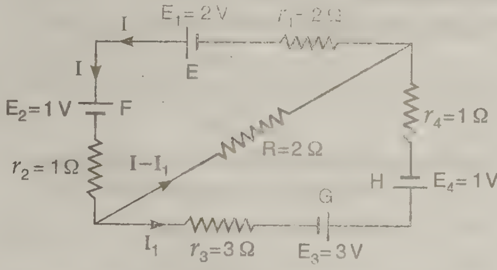

Fig. 2.04

For the closed part ABDA :

$$E_1 - E_2 = I r_1 + I r_2 + (I - I_1) R$$

or $\quad 2 - 1 = I \times 2 + I \times 1 + (I - I_1) \times 2$

or $\quad 5\,I - 2\,I_1 = 1 \qquad ...(i)$

For the closed part BCDB :

$$E_1 - E_2 = I r_1 + I_1 r_1 + (I - I_1) R$$

or $\quad 3 - 1 = I_1 \times 3 + I_1 \times 1 - (I - I_1) \times 2$

or $\quad -I + 3\,I_1 = 1 \qquad ...(ii)$

Solving the equations (*i*) and (*ii*), we obtain

$$I_1 = \frac{6}{13}\ A \text{ and } I = \frac{5}{13}\ I$$

(*a*) Potential difference between points D and B

$$= (I - I_1) R = \left(\frac{5}{13} - \frac{6}{13}\right) \times 2 = -\frac{2}{13}\ V$$

Therefore, potential difference between points B and D

= – (potential difference between points D and B)

$$= -\left(-\frac{2}{13}\right) = \frac{2}{13}\ V$$

(*b*) The current I_1, flows through cell G from its negative to positive terminal potential. Therefore, potential difference across the terminals of cell G,

$$V_G = E_3 - I_1 r_3 = 3 = \frac{6}{13} \times 3 = \frac{21}{13}\ V$$

The current I_1 flows through cell H from its positive to negative terminal. Therefore, potential difference across the terminals of cell H,

$$V_H = E_4 + I_1 r_4 = 1 + \frac{6}{13} \times 1 = \frac{19}{13}\ V$$

Problem 2.04. In the circuit shown in Fig. 2.05, $E_1 = 3$ V, $E_2 = 2$ V, $E_3 = 1$ V and the resistances $R = r_1 = r_2 = r_3 = 1\,\Omega$

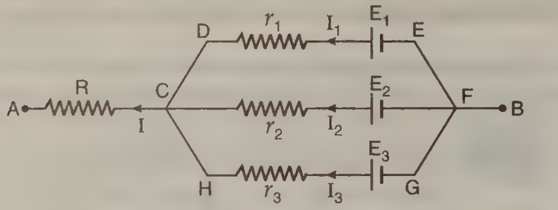

Fig. 2.05

(*a*) Find the potential difference between the points A and B and the current through each branch.

(*b*) If r_2 is short circuited and the point A is connected to the point B, find the currents through E_1, E_2 and E_3 and the resistor R. (*I.I.T. 1981*)

Sol. (*a*) Let I_1, I_2 and I_3 be currents from the cells of e.m.f. $I_1 = 3$ V, $E_2 = 2$ V and $E_3 = 1$ V respectively.

Further, $R = r_1 = r_2 = r_3 = 1\,\Omega$

In the closed part CDEFC of the circuit :

$$I_1 r_1 - I_2 r_2 = E_1 - E_2$$

or $$I_1 \times 1 - I_2 \times 1 = 3 - 2$$

or $$I_1 - I_2 = 1 \qquad \text{...}(i)$$

In the closed part CDEFGHC of the circuit :

$$I_1 r_1 - I_3 r_3 = E_1 - E_3$$

or $$I_1 \times 1 - I_3 \times 1 = 3 - 1$$

or $$I_1 - I_3 = 2 \qquad \text{...}(ii)$$

Since the other end A of resistance R is not connected to point B, no current flows through R *i.e.* I = 0. Therefore, at point C, we have

$$I_1 + I_2 + I_3 = 0 \qquad \text{...}(iii)$$

Solving equations (*i*), (*ii*) and (*iii*), we have

$$I_1 = 1\text{ A};\ I_2 = 0 \text{ and } I_3 = -1\text{ A}$$

The negative value of I_3 indicates that current I_3 does not flow along the indicated path FGHC, but flows along the path CHGF.

The potential difference between points C and F can be calculated across any one of the three paths between C and F. Since $I_2 = 0$,

potential difference between points C and F

$$= E_2 - I_2 r_2 = 2 - 0 \times 1 = 2\text{ V}$$

As there is no current in branches AC and FB,

potential difference between A and B

= potential difference between C and F = **2 V**

(*b*) When resistance r_2 is short circuited and point A is joined to B, the given circuit becomes of the form as shown in Fig. 2.06. The distribution of current is shown in the figure.

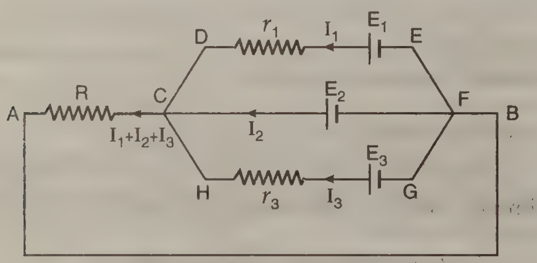

Fig. 2.06

For the closed part CDEFC of the circuit :

$$I_1 r_1 = E_1 - E_2$$

or $$I_1 \times 1 = 3 - 2$$

or $$I_1 = 1\text{ A}$$

For the closed part CFGHC of the circuit :

$$-I_3 r_2 = E_2 - E_3$$

or $$-I_3 \times 1 = 2 - 1$$

or $$I_3 = -1\text{ A}$$

For the closed part ACDEFBKJA of the circuit :

$$I_1 r_1 + (I_1 + I_2 + I_3) R = E_1$$

or $$1 \times 1 + (1 + I_2 - 1) \times 1 = 3$$

or $$I_2 = 2\text{ A}$$

The current through resistor R

$$= I_1 + I_2 + I_3 = 1 + 2 + (-1) = 2\text{ A}$$

Problem 2.05. An electrical circuit is shown in Fig. 2.07. Calculate the potential difference across the resistor of 400 Ω as will be measured by the voltmeter V of resistance 400 Ω, either by applying Kirchhoff's rules or otherwise. (*I.I.T. 1996*)

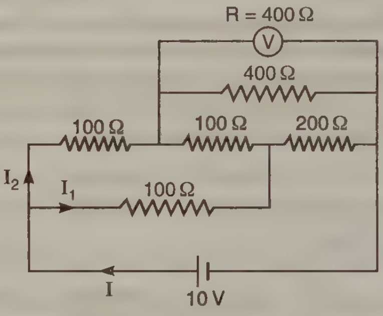

Fig. 2.07

Sol. The parallel combination of the resistance of 400 Ω and the voltmeter of resistance 400 Ω connected across it is equivalent to a resistance of 200 Ω. The given circuit is equivalent to the circuit redrawn as in Fig. 2.08.

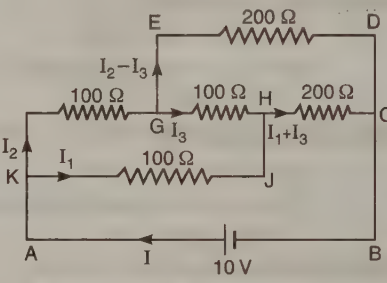

Fig. 2.08

The currents in the various branches of the circuit will be distributed in accordance with Kirchhoff's first law.

In the closed part FGHJKF of the circuit : According to Kirchhoff's second law,

$$I_2 = 100 + I_3 \times 100 - I_1 \times 100 = 0$$

or $$I_1 - I_2 - I_3 = 0 \qquad \text{...}(i)$$

In the closed part ABCHJKA of the circuit : According to Kirchhoff's second law,

$$10 = I_1 \times 100 + (I_1 + I_3) \times 200$$

or $$3 I_1 + 2 I_3 - 0{\cdot}1 = 0 \qquad \text{...}(ii)$$

In the closed part CDEGHC of the circuit : According to Kirchhoff's second law,

$$(I_2 - I_3) \times 200 - (I_1 + I_3) \times 200 - I_3 \times 100 = 0$$

or $I_1 - I_2 + 2{\cdot}5\, I_3 = 0$ ...(*iii*)

Adding equations (*i*) and (*iii*), we have

$$(I - I_2 - I_3) + (I_1 - I_2 + 2{\cdot}5\, I_3) = 0$$

or $1{\cdot}5\, I_3 = 0$ or $I_3 = 0$

Setting $I_3 = 0$ in equation (*ii*), we have

$$2\, I_1 + 2 \times 0 - 0{\cdot}1 = 0 \text{ or } I_1 = \frac{0\cdot1}{3} = \frac{1}{30}\text{ A}$$

Setting $I_1 = \frac{1}{30}$ A and $I_3 = 0$ in equation (*i*), we have

$$\frac{1}{30} - I_2 - 0 = 0 \text{ or } I_2 = \frac{1}{30}\text{ A}$$

The potential difference (measured by voltmeter across 400 Ω resistance of the circuit shown in Fig. 2.07) is equal to potential difference across 200 Ω resistance (in branch DE of the circuit shown in Fig. 2.08). It is given by

$$V = (I_2 - I_3) \times 200 = \left(\frac{1}{30} - 0\right) \times 200 = \mathbf{6{\cdot}67\ V}$$

Problem 2.06. A part of the circuit in a steady state along with the currents flowing in the branches, the values of resistances, etc are shown in the Fig. 2.09. Calculate the energy stored in the capacitor. (*I.I.T. 1986*)

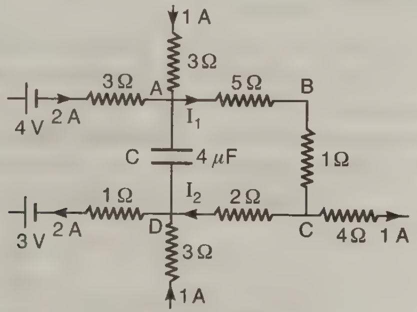

Fig. 2.09

Thought Process

The capacitor offers infinite resistance to d.c. and therefore the branch containing capacitor acts as open path. However, there is potential difference across the two plates of the capacitor and charge is stored inside the capacitor.

Sol. Let I_1 and I_2 be currents in the branches AB and CD of the circuit in the directions as shown in Fig. 2.09. According to Kirchhoff's first law,

at point A : $2 + 1 - I_1 = 0$ or $I_3 = 3$ A

at point D : $1 + 1 + I_2 - 2 = 0$ or $I_2 = 1$ A

For closed part ABCDA of the circuit : Let V be potential difference across the two plates of the capacitor. Then, according to Kirchhoff's second law,

$$I_1 \times 5 + I_1 \times 1 + I_2 \times 2 = V$$

or $V = 3 \times 5 + 3 \times 1 + 1 \times 2 = 20$ V

Now, capacitance of the capacitor,

$$C = 4\,\mu F = 4 \times 10^{-6}\text{ F}$$

Therefore, energy stored in capacitor,

$$U = \frac{1}{2} C V^2 = \frac{1}{2} \times 4 \times 10^{-6} \times (20)^2 = \mathbf{8 \times 10^{-4}\ J}$$

Problem 2.07. In the circuit shown in Fig. 2.10, $E_1 = 3\ E_2 = 2\ E_3 = 6$ V '; C = 5 μF ; $R_1 = 2\ R_2 = 6\ \Omega$; $R_3 = 2\ R_4 = 4\ \Omega$. Find the current in R_3 and the energy stored in the capacitor. (*I.I.T. 1988*)

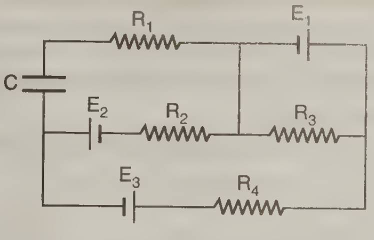

Fig. 2.10

Thought Process

In steady state, a capacitor offers infinite resistance to d.c. and the branch containing the capacitor acts as open path. Therefore, no current flows through the branch of the circuit containing C and R_1 and there is no potential drop across resistance R_1. Hence, the potential difference across the capacitor is equal to potential difference between points A and C.

Sol. The distribution of currents in the various branches of the circuit is as shown in Fig. 2.11.

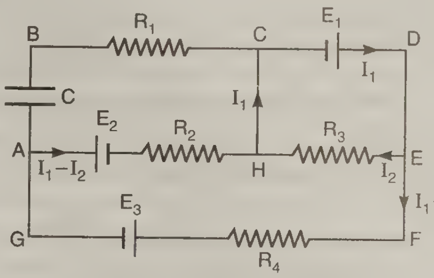

Fig. 2.11

Here, $E_1 = 6$ V ; $E_2 = 2$ V ; $E_3 = 3$ V ;

$C = 5\,\mu F = 5 \times 10^{-6}$ F ;

$R_1 = 6\ \Omega$; $R_2 = 3\ \Omega$, $R_3 = 4\ \Omega$; $R_4 = 2\ \Omega$

In the closed part CDEHC of the circuit : $I_2 R_3 = E_1$

or $I_2 = 4 = 6$ or $I_2 = 1{\cdot}5$ A

Therefore, current through resistance $R_3 = 1{\cdot}5$ A

In the closed part AHEFGA of the circuit :

$$(I_1 - I_2) \times R_2 - I_2 R_3 + (I_1 - I_2) R_4 = -E_2 - E_3$$

or $(I_1 - 1{\cdot}5) \times 3 - 1{\cdot}5 \times 4 + (I_1 - 1{\cdot}5) \times 2 = -2 - 3$

or $I_1 = 1{\cdot}7$ A

Let V_A an V_C be potentials at points A and C respectively. As the current is flowing along the path AHC,

$V_A = V_C$ + potential drop across $R_2 + E_2$

or $V_A - V_C = (I_1 - I_2) R_2 + E_2$

$= (1{\cdot}7 - 1{\cdot}5) \times 2 + 2 = 2{\cdot}4$ V

As the branch ABC contains capacitor, no current flows through R_1 and hence there is no potential difference across R_1. Therefore,

potential difference across capacitor

$= V_A - V_C = 2{\cdot}4$ V

Energy stored in capacitor, $U = \frac{1}{2} C V^2$

$$= \frac{1}{2} \times 5 \times 10^{-6} \times (2{\cdot}4)^2 = \mathbf{1{\cdot}44 \times 10^{-5}\ J}$$

Problem 2.08. A circuit containing a two position switch S is shown in Fig. 2.12. $E_1 = 12$ V, $E_2 = 3$ V, $R_1 = R_2 = R_3 = 2\ \Omega$, $R_4 = 3\ \Omega$, $R_5 = 1\ \Omega$, $C = 2\ \mu F$, $L = 10$ mH.

(a) The switch S is in position 1. Find the potential difference $(V_A - V_B)$ and the rate of production of Joule heat in R_1.

(b) If now the switch S is put in position 2, find the steady state current in R_4. *(I.I.T. 1991)*

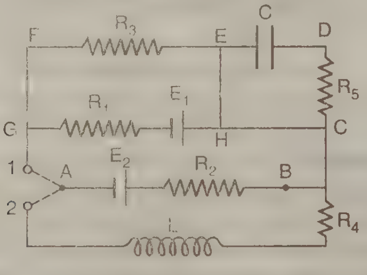

Fig. 2.12

Thought Process

In the steady state, a capacitor offers infinite resistance to d.c. but an inductor offers zero resistance to d.c. Therefore, in the steady state, the capacitor acts as an open path and the inductor as a conducting path.

Sol. (a) When the switch S is in position 1 : In this position of the switch, only the part of the circuit shown in Fig. 2.13 is effective. The distribution of currents is also shown in the figure.

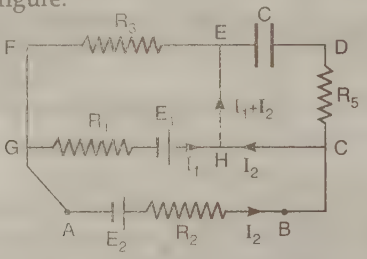

Fig. 2.13

For the closed part ABCHGA of the circuit : According to Kirchhoff's second law,

$$I_2 R_2 - I_1 R_1 = E_2 - E_1$$

or $\quad I_2 \times 2 - I_1 \times 2 = 3 - 12$

or $\quad 2 I_1 - 2 I_2 = 9 \quad \quad ...(i)$

For the closed part EFGHE of the circuit : Applying Kirchhoff's second law,

$$I_1 R_1 - I_1 + (I_1 + I_2) R_3 = E_1$$

or $\quad I_1 \times 2 + (I_1 + I_2) \times 2 = 12$

or $\quad 2 I_1 + I_2 = 6 \quad \quad ...(ii)$

Solving equations (*i*) and (*ii*), we have

$$I_1 = 3{\cdot}5\text{ A} ; I_2 = -1\text{ A}$$

Let V_A and V_B be potentials at points A and B respectively. As the negative terminal of battery E_1 is connected to point A, we have

$$V_A - V_B = -3 + I_2 R_2 = -3 + (-1) \times 2 = \mathbf{-5\ V}$$

Rate of production of heat in $R_1 = I_1^2 R_1$

$$= (3{\cdot}5)^2 \times 2 = \mathbf{24{\cdot}5\ W}$$

(b) When the switch S is in position 2 : In this position of the switch, only the part of the circuit shown in Fig. 2.14 is effective. In the steady state, the ohmic resistance of inductance is zero.

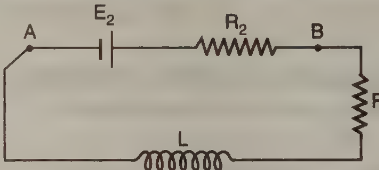

Fig. 2.14

Therefore, total resistance of the circuit in steady state,

$$= R = R_2 + R_4 = 2 + 3 = 5\ \Omega$$

The current in the resistance R_4 will be the same as the current in the circuit in steady state. Therefore,

$$\text{current in resistance } R_4 = \frac{E_2}{R} = \frac{3}{5} = \mathbf{0{\cdot}6\ A}$$

Problem 2.09. In a Wheatstone bridge, the four resistance arms of the bridge are AB = 2 Ω, BC = 3 Ω, CD = 4 Ω and DA = 1Ω. A cell of e.m.f. 2 V and negligible internal resistance is connected across AC and a galvanometer of resistance 10 Ω, is connected between B and D. Find the current through the galvanometer. *(Karnataka, 1992)*

Sol. Let $P = 2\ \Omega$; $Q = 3\ \Omega$; $S = 4\ \Omega$;

$$R = 1\ \Omega, E = 2\text{ V and } G = 10\ \Omega$$

The distribution of current in various branches is as shown in Fig. 2.15.

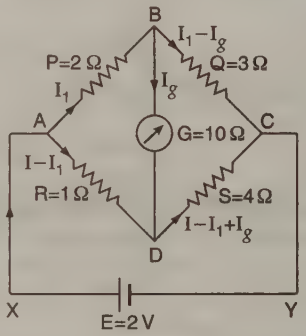

Fig. 2.15

For the closed part ABDA of the circuit :

$$I_1 \times P + I_g \times G - (I - I_1) R = 0$$

or $\quad I_1 \times 2 + I_g \times 10 - (I - I_1) 1 = 0$

or $\quad 3 I_1 + 10 I_g - I = 0 \quad \quad ...(i)$

For the closed part BCDB of the circuit :

$$(I_1 - I_g) Q - (I - I_1 + I_g) S - I_g \times G = 0$$

or $\quad (I_1 - I_g) \times 3 - (I - I_1 + I_g) \times 4 - I_g \times 10 = 0$

or $\quad 7 I_1 - 17 I_g - 4 I = 0 \quad \quad ...(ii)$

For the closed part ABC YXA of the circuit :

$$I_1 \times P + (I_1 = I_g) Q = E$$

or $\quad I_1 \times 2 + (I_1 - I_g) \times 3 = 2$

or $\quad 5 I_1 - 3 I_g = 2 \quad \quad ...(iii)$

From equation (*i*), we have

$$I = 3 I_1 + 10 I_g$$

Substituting for I in equation (*ii*), we have

or $\quad 7 I_1 - 17 I_g - 4 (3 I_1 + 10 I_g) = 0$

or $\quad 5 I_1 + 57 I_g = 0 \quad \quad ...(iv)$

Subtracting equation (*iii*) from (*iv*), we have

$$60\, I_g = -2 \text{ or } I_g = -\frac{1}{30} \text{ A}$$

The negative sign shows that current flows from point B.

Problem 2.10. A thin uniform wire AB of length 1 m, nknown resistance X and a resistance of 12 Ω are ected by thick conducting strips as shown in Fig. 2.16.

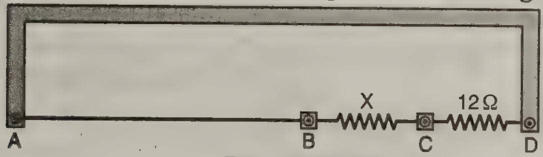

Fig. 2.16

attery and a galvanometer (with a sliding jockey ecting to it) are also available. Connections are to be e to measure the unknown resistance X using the ciple of Wheatstone bridge. Answer the following tions :

(*a*) Are there positive and negative terminals on the anometer ?

(*b*) Copy the figure in your answer book and show the ery and the galvanometer (with jockey) connected at opriate points.

(*c*) After appropriate connections are made, it is found no deflection takes place in the galvanometer, when the sliding jockey touches the wire at a distance of 60 cm from A. Obtain the value of the resistance X. (*I.I.T. 2002*)

Sol. (*a*) A galvanometer is used to detect current in the circuit. There are **no positive or negative terminals** on the galvanometer.

(*b*) To measure the unknown resistance, the galvanometer (G) and battery should be connected in the circuit as shown in Fig. 2.17.

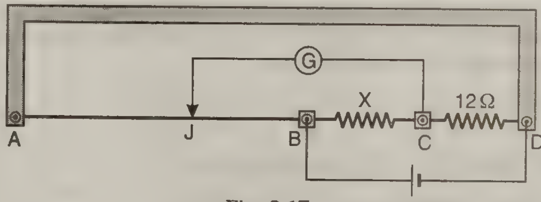

Fig. 2.17

(*c*) Here, AJ = 60 cm

∴ BJ = 100 – 60 = 40 cm

Since the Wheatstone bridge is balanced,

$$\frac{X}{12} = \frac{R_{BJ}}{R_{AJ}} \quad \text{or} \quad \frac{X}{12} = \frac{40}{60}$$

$$\text{or} \quad X = \frac{12 \times 40}{60} = 8\ \Omega$$

Chapter 3. Thermal effects of current

Problem 3.01. The walls of a closed cubical box of 50 cm are made of a material of thickness 1 mm and nal conductivity 4×10^{-4} s^{-1} cm^{-1}°C^{-1}. The interior of ox maintained at 100°C above the outside temperature heater placed inside the box and connected across a 400 :. source. Calculate the resistance of the heater. (*I.I.T. 1971*)

Sol. Here, $K = 4 \times 10^{-4}$ cal s^{-1} cm^{-1} °C^{-1} ;

$$\theta_2 - \theta_1 = 100°\text{C} \,;\, d = 1 \text{ mm} = 0{\cdot}1 \text{ cm} \,;$$

Surface area of the six faces of the cubical box,

$$A = 6 \times (50 \times 50) = 15000 \text{ cm}^2$$

Let Q_1 be the heat escaping the box from its six faces per nd. Then,

$$Q_1 = \frac{K A (\theta_2 - \theta_1)}{d} = \frac{4 \times 10^{-4} \times 15000 \times 100}{0{\cdot}1}$$

$$= 6000 \text{ cal } = 6000 \times 4{\cdot}2 \text{ J}$$

If R is the resistance of the heater, then heat produced econd,

$$Q_2 = I^2 R\, t = \frac{V^2}{R} = \frac{(400)^2}{R}$$

Since the heater maintains a constant temperature inside ox, it follows that $Q_1 = Q_2$

$$\text{or} \quad \frac{(400)^2}{R} = 6000 \times 4{\cdot}2 \text{ or } R = 6{\cdot}35 \text{ W}$$

Problem 3.02. A fuse made of lead wire has an area of -section 0·2 mm². On short circuiting, the current in use wire reaches 30 A. How long after the short ting will the fuse begin to melt ? For lead, specific heat cal g^{-1} °C^{-1}, melting point = 327 °C, density = 11·34 $^{-3}$ and the resistivity = 22× 10^{-6} Ω cm. Initial tempera- of the wire is 20°C. Neglect heat losses. (*I.I.T. 1976*)

Sol. Let *l* (cm) be length of the fuse wire.

Here, area of cross-section of wire,

$$A = 0{\cdot}2 \text{ mm}^2 = 0{\cdot}2 \times 10^{-2} \text{ cm}^2$$

volume of wire, $A\, l = 0{\cdot}2 \times 10^{-2} \times l$ cm^3

and density of the material of wire, = 11·34 g cm^{-3}

Therefore, mass of wire, $m = A\ l \times$ density

$$= 0{\cdot}2 \times 10^{-2} \times l \times 11{\cdot}34 = 2{\cdot}268 \times 10^{-2}\, l$$

Initial temperature, $\theta_1 = 20°$C ; melting point, $\theta_2 = 327°$C

Specific heat of the fuse wire, $c = 0{\cdot}032$ cal g^{-1} °C^{-1}

Therefore, heat required by the wire before it starts melting,

$$H = m\,c\,(\theta_1 - \theta_2) = 2{\cdot}268 \times 10^{-2}\, l \times 0{\cdot}032 \times (327 - 20)$$

$$= 0{\cdot}223\, l \text{ cal} = 0{\cdot}223 \times 4{\cdot}21\, l \text{ joule} \qquad \ldots(i)$$

Now, resistivity of wire, $\rho = 22 \times 10^{-6}\ \Omega$

Area of cross-section of the wire,

$$A = 0{\cdot}22 \text{ mm}^2 = 0{\cdot}2 \times 10^{-2} \text{ cm}^2$$

$$\text{Resistance of wire, } R = \rho \frac{l}{A} = 22 \times 10^{-6} \times \frac{l}{0{\cdot}2 \times 10^{-2}}$$

$$= 1{\cdot}1 \times 10^{-2}\, l$$

Current through the wire on short circuiting, I = 30 A

Suppose that the wire begins to melt after time *t*.

Then, $H = I^2 Rt = 30^2 \times 1{\cdot}1 \times 10^{-2}\, l\, 5\, t = 9{\cdot}9\, l\, t \qquad \ldots(ii)$

From equations (*i*) and, (*ii*), we have

$9{\cdot}9\, l\, t = 0{\cdot}223 \times 4{\cdot}2\, l$ or $t = 0{\cdot}095$ s

Problem 3.03. An electric kettle has two thermal coils. When a current is passed in one of them, water in kettle boils in 6 minutes and when current is passed in other one, the water boils in 8 minutes. If both the coils are joined in (*a*) series (*b*) parallel, how long will it take in boiling water ? (*I.I.T. 1975*)

Sol. Let R_1 and R_2 be the resistances of the first and second thermal coil respectively. Suppose that V is the voltage of main line. Further, suppose that the heat required to boil the water in the kettle is H.

If t_1 is the time in which water boils, when first thermal coil is used, then,

$$H = \frac{V^2}{R_1} t_1 \qquad \text{or} \qquad R_1 = \frac{V^2}{H} t_1$$

Similarly, if t_2 is the time in which water boils, when second thermal coil is used, then

$$H = \frac{V^2}{R_2} t_1 \qquad \text{or} \qquad R_2 = \frac{V^2}{H} t_2$$

(a) When coils are joined in series :

The net resistance of the two coils, $R = R_1 + R_2$

If water boils is time t, then

$$H = \frac{V^2}{R} t$$

$$\text{or} \qquad t = \frac{H}{V^2} R = \frac{H}{V^2}(R_1 + R_2)$$

$$= \frac{H}{V^2}\left(\frac{V^2}{H} t_1 + \frac{V^2}{H} t_2\right)$$

$$= t_1 + t_2 = 6 + 8 = \mathbf{14\ min}$$

(b) When coils are joined in parallel :

The net resistance of the two coils, $R' = \dfrac{R_1 R_2}{R_1 + R_2}$

If water boils in time t', then

$$H = \frac{V^2}{R'} t'$$

$$\text{or} \qquad t' = \frac{H}{V^2} R' = \frac{H}{V^2}\left(\frac{R_1 R_2}{R_1 + R_2}\right)$$

$$= \frac{H}{V^2}\left[\frac{\frac{V^2}{H} t_1 \times \frac{V^2}{H} t_2}{\frac{V^2}{H} t_1 + \frac{V^2}{H} t_2}\right]$$

$$= \frac{t_1 t_2}{t_1 + t_2} = \frac{6 \times 8}{6 + 8} = \frac{\mathbf{24}}{\mathbf{7}}\ \mathbf{min}$$

Problem 3.04. A heater is designed to operate with a power of 1000 W in 100 V line. It is connected to two resistances of 10 Ω and R as shown in Fig. 3.01. If the hea is now giving a power of 62·5 W, calculate the value of resistance R. *(I.I.T. 19*

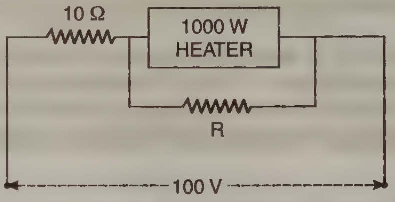

Fig. 3.01

Sol. Here, power of the heater in 100 V line,

$$P_1 = 1000\ \text{W}$$

Therefore, resistance of the heater,

$$R_1 = \frac{V_1^2}{P_1} = \frac{100^2}{1000} = 10\ \Omega$$

In the circuit shown in Fig. 3.01, the heater hav resistance R_1 (= 10 Ω) is giving a power 62·5 W.

If V_2 is potential difference across the parallel combi tion of heater and the resistance R, then,

$$R_1 = \frac{V_2^2}{P_2}$$

$$\text{or} \qquad V_2 = \sqrt{P_2 R_1} = \sqrt{62 \cdot 5 \times 10} = 25\ \text{V}$$

Therefore, potential difference across 10 Ω resistanc 100 – 25 = 75 V

If I is current through 10 Ω resistance, then

$$I = \frac{75}{10} = 7 \cdot 5\ \text{A}$$

It follows that current through parallel combinatior heater and resistance R is also 7·5 A. If X is resistance of parallel combination of heater and resistance R, then

$$\frac{25}{X} = 7 \cdot 5$$

$$\text{or} \qquad X = \frac{25}{7 \cdot 5} = \frac{10}{3}\ \Omega$$

$$\text{But} \qquad \frac{1}{X} = \frac{1}{R} + \frac{1}{R_1}$$

$$\text{or} \qquad \frac{1}{R} = \frac{1}{X} - \frac{1}{R_1} = \frac{3}{10} - \frac{1}{10} = \frac{1}{5}$$

$$\therefore \qquad R = 5\ \Omega$$

Chapter 4. Chemical effects of current

Problem 4.01. A piece of metal weighing 200 g is to be electroplated with 5% of its weight in gold. If the strength of the available current is 2 A, how long would it take to deposit the required amount of gold ? E.C.E. of hydrogen = 1·044 × 10^{-5} g C^{-1}, atomic weight of gold = 197·1, atomic weight of hydrogen = 1·008. *(Roorkee, 1988)*

Sol. Here, mass of the piece of metal = 200 g

Mass of gold to be deposited, $m = \dfrac{200 \times 5}{100} = 10\ \text{g}$

Current passed, $I = 2\ \text{A}$

Electrochemical equivalent of hydrogen,

$$z_1 = 1 \cdot 044 \times 10^{-5}\ \text{g C}^{-1}$$

Chemical equivalent of hydrogen,

$$E_1 = \frac{\text{atomic weight}}{\text{valency}} = \frac{1 \cdot 008}{1} = 1 \cdot 008\ \text{g mole}$$

Chemical equivalent of gold,

$$E_2 = \frac{\text{atomic weight}}{\text{valency}} = \frac{197 \cdot 1}{3} = 65 \cdot 7\ \text{g mole}$$

Let z_2 be electrochemical equivalent of gold. Then, fr Faraday's second law of electrolysis,

$$z_2 = z_1 \times \frac{E_2}{E_1} = 1 \cdot 044 \times 10^{-5} \times \frac{65 \cdot 7}{1 \cdot 008}$$

$$= 68 \cdot 05 \times 10^{-5}\ \text{g C}^{-1}$$

If t is the time taken to deposit the required amount of gold, then

$$m = z_2 I t$$

or

$$t = \frac{m}{z_2 I} = \frac{10}{68 \cdot 05 \times 10^{-5} \times 2} = \mathbf{7347 \cdot 5 \ s}$$

Chapter 5. Thermoelectric effect

Problem 5.01. A thermocouple is made of iron and nickel and the difference of temperature between their junctions is 100°C. Find the thermo-e.m.f. developed across such a thermocouple, when the thermo-e.m.f. for iron-lead thermocouple is 12·5 μV °C^{-1} and for nickel-lead thermocouple is 15 μV °C^{-1}.

Sol. According to law of intermediate metals,

$$E_{Fe}^{Ni} = E_{Fe}^{Pb} + E_{Pb}^{Ni}$$

Here, $E_{Fe}^{Pb} = 12{\cdot}5 \ \mu V \ °C^{-1}$

and $E_{Pb}^{Ni} = 15 \ \mu V \ °C^{-1}$

$\therefore$ $E_{Fe}^{Ni} = 12{\cdot}5 + 15 = 27{\cdot}5 \ \mu V \ °C^{-1}$

Hence, when the difference of temperature between the junctions is 100°C,

thermo e.m.f. developed = 27·5 × 100 = **2750 μV**

MULTIPLE CHOICE QUESTIONS FROM COMPETITIVE EXAMINATIONS

Chapter 1. Electric current, Resistance and E.M.F.

PART I. TEXT-BASED QUESTIONS

1. One ampere is equivalent to
(A) 1 coulomb second (B) 1 coulomb second^{-1}
(C) 1 joule second (D) 1 joule second^{-1}

2. Assuming that the charge of an electron is $1{\cdot}6 \times 10^{-19}$ C, the number of electrons passing through a section of wire per second, when the wire carries a current of 1 A is
(A) $0{\cdot}625 \times 10^{19}$ (B) $1{\cdot}6 \times 10^{-19}$
(C) $1{\cdot}6 \times 10^{19}$ (D) $0{\cdot}625 \times 10^{17}$
(N.C.E.R.T. 1974)

3. In the Bohr's model of hydrogen atom, the electron moves around the nucleus in a circular orbit of radius 5×10^{-11} m. Its time period is $1{\cdot}5 \times 10^{-16}$ s. The current associated with the electron motion is
(A) zero (B) $1{\cdot}6 \times 10^{-19}$ A
(C) 0·17 A (D) $1{\cdot}07 \times 10^{-3}$ A
(M.N.R. 1992)

4. Unit of resistance is
(A) volt × ampere (B) volt^2 × ampere
(C) volt/ampere (D) ampere/volt
(A.F.M.C. 1997)

5. A solenoid is at potential difference of 60 V. If the current flowing through it is 15 A, then resistance of the solenoid will be
(A) 4 Ω (B) 8 Ω
(C) 0·25 Ω (D) 2 Ω *(A.F.M.C. 1995)*

6. The resistance of a wire is R. If the length of the wire is doubled, then its resistance will be
(A) 2 R (B) 4 R
(C) R (D) 0·25 R
(A.F.M.C. 1995 ; Karnataka, 1992, 1989)

7. Three copper wires of lengths and cross-sectional areas are (l, A) ; (2 l, A/2) and (l/2, 2 A). Resistance is minimum in
(A) wire of cross-sectional area A/2.
(B) wire of cross-sectional area A.
(C) wire of cross-sectional area 2 A.
(D) same in all the three cases. *(C.B.S.E. 1997)*

8. The specific resistance of a wire 1·1 m long, 0·4 mm in diameter and having a total resistance of 4·2 ohm will be
(A) $4{\cdot}97 \times 10^{5}$ Ω m (B) 48×10^{-8} Ω m
(C) 48×10^{4} Ω m (D) none of these.

9. Two copper wires, one of length 1 m and the other of length 9 m, are found to have the same resistance. Their diameters are in the ratio
(A) 3 : 1 (B) 1 : 9
(C) 9 : 1 (D) 1 : 3
(Karnataka Entrance, 1991)

10. A metallic wire of resistance 40 Ω is stretched to twice its length. Its new resistance would be approximately :
(A) 20 Ω (B) 80 Ω
(C) 120 Ω (D) 160 Ω *(N.C.E.R.T. 1974)*

11. A wire of resistance 10 Ω is elongated by 10%. The resistance of the elongated wire is
(A) 10·1 Ω (B) 11·1 Ω
(C) 12·1 Ω (D) 13·1 Ω
(C.B.S.E. 1999, 1991 ; A.F.M.C. 1998)

12. When a piece of aluminium wire of finite length is drawn through a series of dies to reduce its diameter to half its original value, its resistance will become
(A) two times (B) four times
(C) eight times (D) sixteen times.
(N.C.E.R.T. 1974)

13. A certain piece of copper is to be shaped into a wire of minimum resistance. Its length and diameter should be
(A) L, D (B) 2 L, D/ $\sqrt{2}$
(C) L/4, 2 D (D) L/2, $\sqrt{2}$ D
(Karnataka Entrance 1987, 1985)

14. A uniform wire of resistance R is uniformly compressed along its length, until its radius becomes n times the original radius. Now, the resistance of the wire becomes
(A) R/n (B) n R
(C) R/n^2 (D) R/n^4 *(Karnataka, 2000)*

15. Two wires of the same metal have same length, but their cross-sections are in the ratio 3 : 1. They are joined in series. The resistance of thicker wire is 10 Ω. The total resistance of the combination will be
(A) 5/2 Ω (B) 40/3 Ω
(C) 40 Ω (D) 100 Ω *(C.B.S.E. 1995)*

16. The appropriate material to be used in the construction of resistance boxes out of the following is :
(A) copper (B) iron
(C) manganin (D) aluminium
(N.C.E.R.T. 1990)

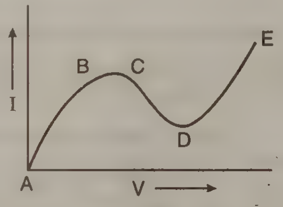
17. Identify the material commonly used for making coils of a resistance box :
(A) Molybdenum (B) Manganese
(C) Manganin (D) Magnesium
(Karnataka Entrance, 1987)

18. The reciprocal of resistance is
(A) conductance (B) specific resistance
(C) voltage (D) current *(A.F.M.C. 1995)*

19. If the resistivity of an alloy is ρ' and that of constituent metals is ρ, then
(A) $\rho' = \rho$ (B) $\rho' < \rho$
(C) $\rho' > \rho$
(D) there is no simple relation between ρ' and ρ.
(Karnataka Entrance, 1994)

20. The resistance of a discharge tube is
(A) ohmic (B) non-ohmic
(C) zero (D) both (A) and (B)
(A.F.M.C. 1996)

21. From the graph between current (I) and voltage (V) as shown in the figure, identify the portion corresponding to negative resistance :



(A) AB (B) BC
(C) CD (D) DE *(C.B.S.E. 1997)*

22. Carbon resistors used in electronic circuits are marked for their resistance value and tolerance by a colour scheme. A given resistor has a colour scheme brown, black, green and gold. Its value (in ohm) is

(A) $3{\cdot}2 \times 10^5 \pm 5\,\%$ (B) $1{\cdot}0 \times 10^6 \pm 10\%$
(C) $1{\cdot}0 \times 10^6 \pm 5\%$ (D) $1{\cdot}0 \times 10^3 \pm 5\%$
(Karnataka Entrance, 1994)

23. When a current flows in a conductor, the order of magnitude of drift velocity of electrons through it is
(A) 10^{-7} cm s^{-1} (B) 10^{-2} cm s^{-1}
(C) 10^4 mm s^{-1} (D) 0·5 mm s^{-1}
(C.P.M.T. 1986)

24. The ratio of drift velocity to that of the thermal velocity of an electron in a conductor is :
(A) 10^{-6} (B) 10^{-8}
(C) 10^{-5} (D) 10^{-10}

25. Assume that each atom of copper contributes one free electron. The density of copper is 9 g cm^{-3} and atomic weight of copper is 63. If the current flowing through a copper wire of 1 mm diameter is 1·1 ampere, the drift velocity of electrons will be
(A) 0·1 mm s^{-1} (B) 0·2 mm s^{-1}
(C) 0·3 mm s^{-1} (D) 0·5 mm s^{-1} *(C.P.M.T. 1989)*

26. Resistance of a conductor increases with the rise of temperature, because
(A) relaxation time decreases.
(B) relaxation time increases.
(C) electron density decreases.
(D) electron density increases.

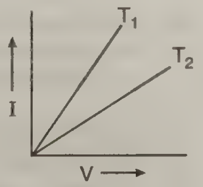
27. Si and Cu are cooled to a temperative of 300 K. Then resistivity
(A) for Si increases and for Cu decreases
(B) for Cu increases and for Si decreases
(C) decreases for both Si and Cu
(D) increases for both Si and Cu. *(C.B.S.E. 2001)*

28. A piece of copper and another of germanium are cooled from room temperature to 80 K. The resistance of
(A) each of them increases.
(B) each of them decreases.
(C) copper increases, germanium decreases.
(D) copper decreases and germanium increases.
(I.I.T. 1980)

29. A piece of germanium and another of copper are stated to experience a rise in temperature. The resistance of
(A) each of them increases.
(B) each of them decreases.
(C) copper increases and germanium decreases.
(D) copper decreases and germanium increases.
(C.E.T. 1998)

30. The specific resistance of a conductor increases with
(A) increase in temperature
(B) increase in cross-sectional area
(c) decrease in length.
(d) decrease in cross-scetional area. *(C.B.S.E. 2002)*

31. The current I and voltage V curves for a given metallic wire at two different temperatures T_1 and T_2 are shown in the figure. Then,
(A) $T_1 > T_2$
(B) $T_1 < T_2$
(C) $T_1 = T_2$
(D) $T_1 = 2\,T_2$



(I.I.T. 1989)

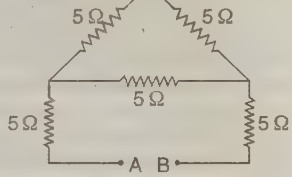
32. The resistance of a conductor is 5 ohm at 50°C, and 6 ohm at 100°C. What is its resistance at 0°C ?
(A) 1 ohm (B) 2 ohm
(C) 3 ohm (D) 4 ohm
(Karnataka Entrance, 2000, 1989, 1988)

33. The temperature coefficient of resistance of wire is 0·00125 °C^{-1}. At 300 K, its resistance is 1 ohm. The resistance of the wire will be 2 ohm at
(A) 1154 K (B) 1100 K
(C) 1400 K (D) 1127 K *(I.I.T. 1980)*

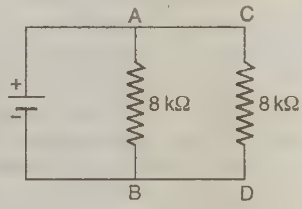
34. Which of the following has a negative temperature coefficient ?
(A) C (B) Fe
(C) Mn (D) Ag *(A.F.M.C. 1995)*

35. Three resistances each of 4 Ω are connected to form a triangle. The resistance between any two terminals is
(A) 12 Ω (B) 2 Ω
(C) 6 Ω (D) 8/3 Ω
(C.B.S.E. 1993 ; Karnataka 1992, 1990)

36. What is the resistance between points A and B ?
(A) 15 Ω
(B) 13·3 Ω
(C) 6 Ω
(D) 25 Ω

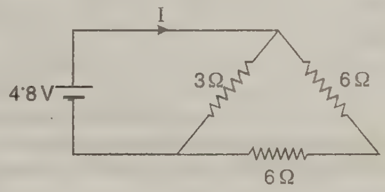


37. Find the equivalent resistance of a two branched circuit as shown in figure :
(A) 2 kΩ
(B) 3 kΩ
(C) 4 kΩ
(D) 5 kΩ



(A.F.M.C. 1997)

38. The current in the given circuit is



(A) 8·31 A (B) 6·82 A
(C) 4·92 A (D) 2 A
(C.B.S.E. 1999, 1997 ; similar C.E.T. 1999)

39. Two resistances r_1 and r_2 ($r_1 < r_2$) are joined in parallel. The equivalent resistance R is such that
(A) $r_2 < R < r_1 + r_2$ (B) $R > r_1 + r_2$
(C) $R < r_1$ (D) $r_1 < R < r_2$
(Karnataka, 2000)

40. A metal wire of resistance R is cut into three equal pieces that are then connected side by side to form a new wire, the length of which is equal to one third of the original length. The resistance of this new wire is
(A) R (B) 3 R
(C) R/9 (D) R/3 *(C.E.T. 1998)*

41. n equal resistors are first connected in series and then connected in parallel. What is the ratio of the maximum to the minimum resistance ?
(A) n (B) $1/n^2$
(C) n^2 (D) $1/n$
(Karnataka Entrance, 1994)

42. ***n*** **conductors, each of resistance** ***r*****, when connected in parallel, give an effective resistance R. What will be resistance, if they are connected in series ?**

(A) $n^2 R$ (B) $\frac{R}{n^2}$

(C) $\frac{R^2}{n}$ (D) $\frac{n^2}{R}$

43. A student has 10 resistors each of resistance ***r*****. The minimum resistors made by him from the given resistors is**

(A) $10\,r$ (B) $\frac{r}{10}$

(C) $\frac{r}{100}$ (D) $\frac{r}{5}$ *(A.F.M.C. 1995)*

44. An unknown resistance is connected in parallel with a resistance of 4 Ω. Similarly, two other resistances of 2 and 3 Ω are connected in parallel. The effective resistance, when these two combinations are connected in series, is 3·6 Ω. The value of the unknown resistance is (in Ω)

(A) 1 (B) 4

(C) 5 (D) 6 *(Karnataka Entrance, 1987)*

45. Four resistances R_1, R_2, R_3 and R_4 are connected in parallel. The resultant resistance R is

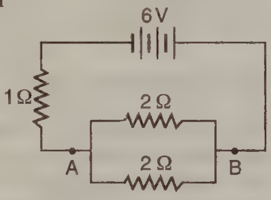
(A) equal to sum of the four resistances.

(B) greater than the sum of the four resistances.

(C) less than the sum of the four resistances.

(D) less than any of the four resistances.

46. Refer to the figure. Assuming the internal resistance of the battery to be negligible, a voltmeter connected between the points A and B should read



(A) 0 V

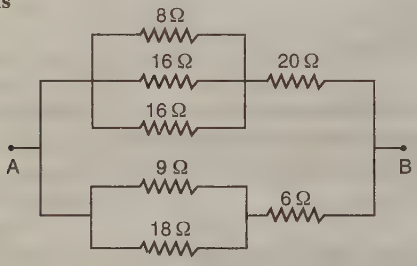
(B) 1·2 V

(C) 3·0 V

(D) 4·8 V

(Karnataka Entrance, 1992, 1988)

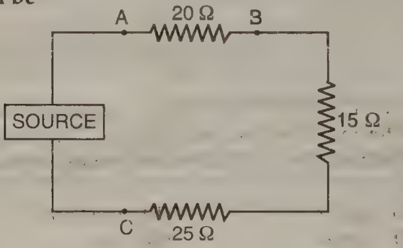
47. The equivalent resistance of the arrangement of resistances shown between the points A and B in the figure given below is



(A) 6 Ω (B) 8 Ω

(C) 16 Ω (D) 24 Ω *(C.P.M.T. 1990)*

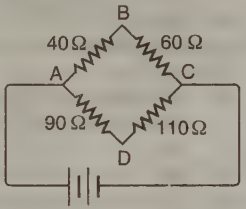
48. In the electric circuit given below, the voltage between the points A and B is 10 V. The voltage between the points B and C will be



(A) 5 V (B) 10 V

(C) 15 V (D) 20 V

49. Four resistances of 40 Ω, 60 Ω, 90 Ω and 110 Ω are connected as shown to a battery of e.m.f. 4 V and negligible internal resistance. Then, the potential difference between the points B and D is



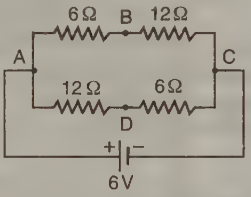
(A) −0·2 V

(B) 0·2 V

(C) 1 V

(D) −1 V

50. In the circuit as shown in the figure, the potential difference between the points B and D is



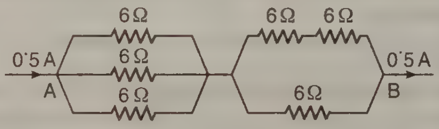
(A) 1 V

(B) 2 V

(C) 3 V

(D) 4 V

51. Resistance of 6 ohm each are connected in the manner shown in given figure. With the current 0·5 ampere as shown in figure, the potential difference $V_A - V_B$ is



(A) 3·0 volt (B) 3·6 volt

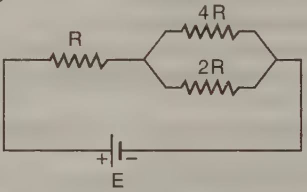
(C) 6·0 volt (D) 7·2 volt *(C.P.M.T. 1989)*

52. Three resistors of 4 Ω, 6 Ω and 12 Ω are connected in parallel and the combination is connected in series with 4 V battery with internal resistance of 2 Ω. The battery current is

(A) 0·5 A (B) 1 A

(C) 2 A (D) 10 A *(C.E.T. 1991)*

53. As shown in figure, the current flowing in the resistor 2 R (in ohm) is



(A) $\frac{2\,E}{R}$ (B) $\frac{2\,E}{7\,R}$

(C) $\frac{E}{7\,R}$ (D) $\frac{E}{R}$ *(C.P.M.T. 1980)*

54. For a cell, the terminal potential difference is 2·2 V, when circuit is open and reduces to 1·8 V, when cell is connected to a resistance R = 5 Ω. The internal registance of cell (***r*****) is**

(A) 10/9 Ω (B) 9/10 Ω

(C) 11/9 Ω (D) 5/9 Ω *(C.B.S.E. 2002)*

55. A primary cell has an e.m.f. 1·5 volt. When short circuited, it gives a current of 3 ampere. The internal resistance of the cell is

(A) 4·5 Ω (B) 2 Ω

(C) 0·5 Ω (D) $\frac{1}{4 \cdot 5}$ Ω *(C.P.M.T. 1983)*

56. **A cell supplies a current of 0·3 A through a resistance of 7 Ω and a current of 0·9 A through a resistance of 2 Ω. The internal resistance of the cell is**
(A) 2·0 Ω (B) 1·2 Ω
(C) 1·0 Ω (D) 0·5 Ω

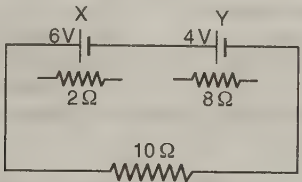
57. **A cell of e.m.f. E is connected across a resistance *r*. The potential difference between the terminals of the cell is found to be V. The internal resistance of the cell must be**
(A) $\frac{2(E-V)V}{r}$ (B) $\frac{2(E-V)r}{E}$
(C) $\frac{(E-V)r}{V}$ (D) $(E-V)r$ *(M.N.R. 1987)*

58. **If E is the e.m.f. of a cell of internal resistance *r* and external resistance R, then potential difference across R is given as**
(A) $V=\frac{E}{(1+r)}$ (B) $V=\frac{ER}{(R+r)}$
(C) $V=\frac{E}{(1+r/R)}$ (D) $V=\frac{E}{1+R/r}$
(Karnataka Entrance, 1986, 1984)

59. **The internal resistance of a cell of e.m.f. 2 V is 0·1 Ω. It is connected to a resistance of 3·9 Ω. The voltage across the cell will be :**
(A) 0·5 V (B) 1·5 V
(C) 1·95 V (D) 2 V *(C.B.S.E. 1999)*

60. **The terminal voltage of a cell of e.m.f. E on short circuting will be**
(A) E (B) E/2
(C) 2 E (D) zero *(A.F.M.C. 1998)*

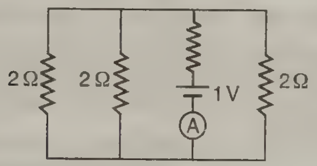
61. **Two cells X and Y are connected to a resistance of 10 Ω as shown in the figure :**



The terminal voltage of cell Y is
(A) zero (B) 2 V
(C) 4 V (D) 10 V

62. **In the above figure, if the polarity of the cell Y is reserved, then the terminal voltage of the cell Y will be :**
(A) 2·8 V (B) 3·8 V
(C) 4·8 V (D) 5·8 V

63. **The reading of the ammeter in the circuit is :**

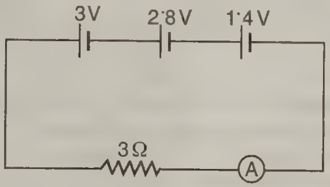


(A) $\frac{1}{8}$ A (B) $\frac{3}{8}$ A
(C) $\frac{1}{2}$ A (D) 2 A

64. **A current of 2·0 A passes through a cell of e.m.f. 1·5 V having internal resistance of 0·15 Ω. The potential difference (measured in volt) across both the terminals of the cell is**
(A) 1·35 (B) 1·50
(C) 1·00 (D) 1·20 *(M.N.R. 1991*

65. ***n* cells each of e.m.f. E volt and internal resistance *r* ohm are connected in series with an external resistance R. The current will increase *n* times that of a single cell, if**
(A) R is very large as compared to the internal resistance.
(B) R is very small as compared to the internal resistance.
(C) R is equal to total internal resistance
(D) regardless of relative magnitudes of R and *r*.
(C.E.T. 1998)

66. **Three cells of e.m.f. 3 V, 2·8 V and 1·4 V are connected in series. Their internal resistances are 0·02 Ω, 0·6 Ω and 1 Ω respectively. If the battery is connected to an external resistance of 3 Ω via a very low resistance ammeter, what would be the reading of the ammeter ?**



(A) 1·0 A (B) 1·5 A
(C) 2·6 A (D) 5 A *(A.F.M.C. 1997)*

67. **If *n* batches of *m* cells (each of emf E and internal resistance *r*) in series are connected in parallel with an external resistance R, then the current I through the external resistance is given by**
(A) $I=\frac{mnE}{(mr+nR)}$ (B) $I=\frac{mnE}{(mR+nr)}$
(C) $I=\frac{mE/n}{(mR+nr)}$ (D) $I=\frac{nE/m}{(mr+nR)}$
(Karnataka Entrance, 1986, 1984)

68. **To get maximum current in a resistance of 3 ohm, one can use *n* rows of *m* cells (connected in series) connected in parallel. If the total number of cells is 24 and the internal resistance of a cell is 0·5 ohm, then**
(A) $m = 12, n = 2$ (B) $m = 8, n = 3$
(C) $m = 6, n = 4$ (D) $m = 2, n = 12$
(N.C.E.R.T. 1980)

69. **Suppose 4 branches of 5 identical cells (in series) are connected in parallel, the internal resistance of each cell being 10 ohm. If the group of cells sends a current of 0·2 ampere through an external resistance of 25 ohm, then the e.m.f. of each cell is (in volt)**
(A) 1·5 (B) 1·25
(C) 2·5 (D) 1·75
(Karnataka Entrance, 1987)

PART II. THOUGHT-BASED QUESTIONS

70. **The potential difference applied to an X-ray tube is 5 kV and the current through it is 3·2 mA. Then the number of electrons striking the target per second is**
(A) 2×10^{16} (B) 5×10^{6}
(C) 1×10^{17} (D) 4×10^{15} *(I.I.T. 2002)*

71. **In a hydrogen discharge tube, it is observed that through a given cross-section $3{\cdot}13 \times 10^{15}$ electrons are moving from right to left and $3{\cdot}12 \times 10^{15}$ protons are moving from left to right. What is the electric current in the discharge tube and what is its direction ?**
(A) 1 mA towards right (B) 1 mA towards left.
(C) 2 mA towards right. (D) 2 mA towards left.
(A.F.M.C. 1996)

72. **A small sphere that carries a charge *q* is whirled in a circle at the end of an insulating string. The angular frequency of rotation is 2 ω. This rotating charge represents a current of**
(A) $q\omega/\pi$ (B) $q\omega/2\pi$
(C) $q\pi/\omega$ (D) $q\omega$ *(C.E.T. 1998)*

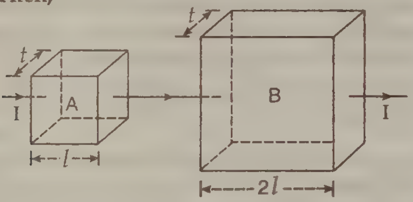
73. A quantity X is given by $\varepsilon_0 L \frac{\Delta V}{\Delta t}$, where ε_0 is the permittivity of free space, L is a length, ΔV is a potential difference and Δt is a time internal. The dimensional formula for X is the same as that of :
(A) resistance (B) charge
(C) voltage (D) current *(I.I.I. 2001)*

74. Masses of three wires of same metal are in the ratio 1 : 2 : 3 and their lengths in the ratio 3 : 2 : 1. Electrical resistance of these wires will be in the ratio of :
(A) 1 : 1 : 1 (B) 1 : 2 : 3
(C) 9 : 4 : 1 (D) 27 : 6 : 1

75. As the temperature of a metallic resistor is increased, the product of resistivity and conductivity
(A) increases. (B) decreases.
(C) may increase or decrease.
(D) remains constant.

76. A wire of length L and 3 identical cells of negligible internal resistances are connected in series. Due to the current, the temperature of the wire is raised by ΔT in time t. A number N of similar cells is now connected in series with a wire of the same material and cross-section but of length 2 L. The temperature of the wire is raised by the same amount ΔT in the same time. The value of N is
(A) 4 (B) 6
(C) 8 (D) 9 *(I.I.T. 2001)*

77. The two metal plates A and B of same material are square in shape and have the same thickness. The side of B is twice that of A. They are connected in the circuit as shown in figure. Then,



(A) the resistance of B is twice that of A.
(B) the resistance of A is twice that of B.
(C) both have the same resistance.
(D) the resistance of A is four times that of B.

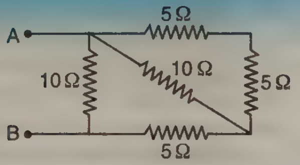
78. A conductor of resistance 8 Ω is bent in the form of circle. What will be resistance between two points on any diameter of the circle ?
(A) 1 Ω (B) 2 Ω
(C) 8 Ω (D) 16 Ω

79. When current flows in a conductor, then the ratio of the intensity of electric field E at any point within the conductor and the current density at a point is called
(A) resistance (B) conductance
(C) specific resistance (D) inductance *(A.F.M.C. 1996)*

80. Which of the following quantities do not change, when a resistor is heated by passing current through it ?
(A) Resistance (B) Resistivity
(C) Drift velocity (D) Number of free electrons.

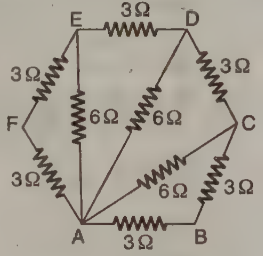
81. You are given several identical resistors each of resistance R = 10 Ω and each capable of carrying a maximum current 1 A. It is required to make suitable combination of these resistors to produce a resistance of 5 Ω, which can carry a current of 4 A . The minimum number of such resistors required is
(A) 4 (B) 10
(C) 8 (D) 20 *(C.B.S.E. 1990)*

82. The effective resistance between the terminals A and B in the circuit is :



(A) 25 Ω
(B) 35 Ω
(C) 10 Ω
(D) 5 Ω

83. Six resistors of 3 Ω are connected along the sides of a hexagon and three resistors of 6 Ω each are connected along AC, AD and AE as shown in the figure. The equivalent resistance between the points A and B is equal to



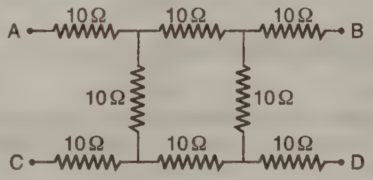
(A) 3 Ω
(B) 9 Ω
(C) 2 Ω
(D) 6 Ω *(A.F.M.C. 1995)*

84. Given three resistors of different values. How many different combinations of these three resistances can be made ?
(A) Six (B) Five
(C) Four (D) Eight

85. Given three equal resistors. How many different combinations of these three resistances can be made ?
(A) Three (B) Four
(C) Five (D) Six *(N.C.E.R.T. 1980)*

86. A technician has only two resistors. By using them singly in series or in parallel, he is able to obtain the resistances of values 3, 4, 12 and 16 Ω. What are the resistances of the two resistors ?
(A) 6 and 10 Ω (B) 4 and 12 Ω
(C) 7 and 9 Ω (D) 5 and 12 Ω
(Karnataka Entrance, 1993)

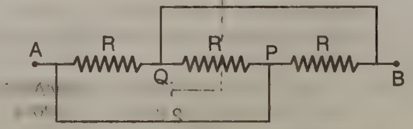
87. What will be the equivalent resistance between the points A and D ?



(A) 10 Ω (B) 20 Ω
(C) 30 Ω (D) 40 Ω *(C.B.S.E. 1996)*

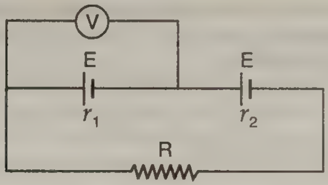
88. An electrical cable of copper has just one wire of radius 9 mm. Its resistance is 5 ohm. The single copper wire of the cable is replaced by 6 different well insulated copper wires each of radius 3 mm. The total resistance of the cable will now be equal to
(A) 7·5 Ω (B) 45 Ω
(C) 90 Ω (D) 270 Ω *(C.P.M.T. 1988)*

89. Find the resistance of the portion of the circuit between the points A and B in the circuit shown in the figure. Points A and P are connected by a copper wire of negligible resistance. Similarly, points B and Q are also connected by a copper wire of negligible resistance.



(A) 3 R
(B) $\frac{R}{3}$
(C) $\frac{3R}{2}$
(D) $\frac{2R}{3}$ *(C.P.M.T. 1990)*

90. **In the diagram shown, the two cells have equal e.m.f. E, but internal resistances are r_1 and r_2. If the reading of the voltmeter is zero, then**



(A) $R = r_1 - r_2$ (B) $R = r_1 + r_2$
(C) $R = 2r_1 - r_2$ (D) $R = 2r_1 + r_2$

(Roorkee, 1983)

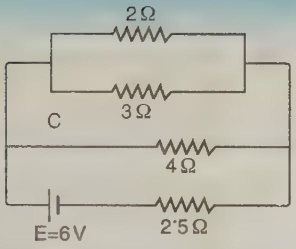
91. **The steady state current in a 2 Ω resistor (see figure), when the internal resistance of the battery is negligible and the capacitance of the capacitor is 0·1 μF is**

(A) 0·3 A

(B) 0·6 A

(C) 0·9 A

(D) 1·3 A



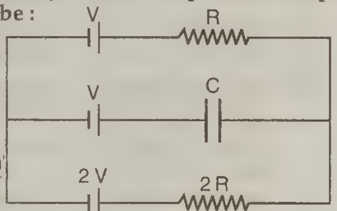
92. In the given circuit with steady current, the potential drop across he capacitor must be :

(A) V

(B) V/2

(C) V/3

(D) 2 V/3 (I.I.T. 2001)



Chapter 2. Electrical measurements

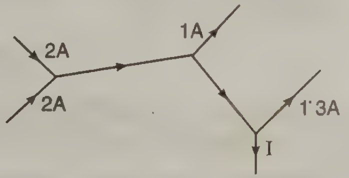
PART I. TEXT-BASED QUESTIONS

1. **Kirchhoff's first law, *i.e.* Σ I = 0 at a junction, deals with the conservation of**

(A) charge (B) energy
(C) momentum (D) angular momentum

(C.B.S.E. 1997)

2. **Figure shows current in a part of electrical circuit. Then, current I is**



(A) 1·7 A (B) 3·7 A
(C) 1·3 A (D) 1 A

(Karnataka, 2000 ; C.P.M.T. 1981)

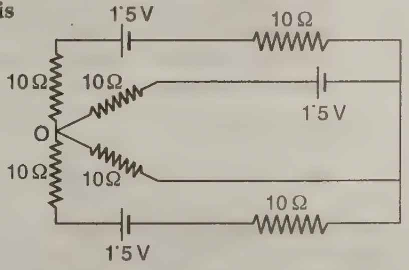
3. **The algebraic sum of the currents at the point O in the following circuit is**

(A) 0 A

(B) 0·75 A

(C) 0·375 A

(D) 1·5 A

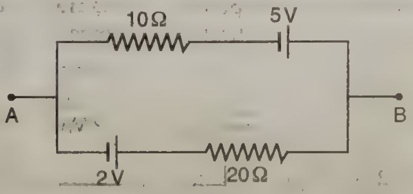


(Karnataka Entrance, 1989)

4. **Two cells of 1·25 V and 0·75 are connected in parallel. The effective voltage will be**

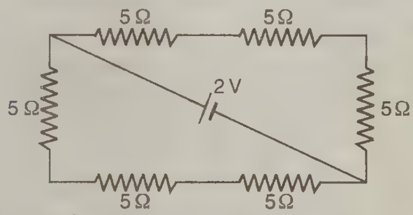
(A) 0·75 V (B) 1·25 V
(C) 2·0 V (D) 0·50 V (C.P.M.T. 1992)

5. **The current in the given circuit is :**



(A) 0·1 A (B) 0·2 A
(C) 0·3 A (D) 0·4 A *(C.B.S.E. 1999)*

6. The potential difference between the points A and B in the figure will be



(A) $\frac{2}{3}$ V (B) $\frac{8}{9}$ V

(C) $\frac{4}{3}$ V (D) 2 V (C.P.M.T. 1991)

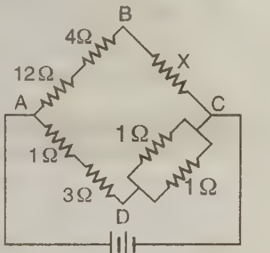
7. In the arrangement of resistances shown in the circuit, the potential difference between points B and D will be zero, when the unknown resistance X is

(A) 4 Ω

(B) 3 Ω

(C) 2 Ω

(D) 1 Ω (C.P.M.T. 1988)



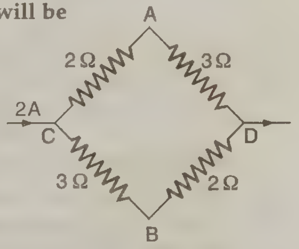
8. A current of 2 A flows in conductors as shown. The potential difference $V_A - V_B$ will be

(A) +2 V

(B) +1 V

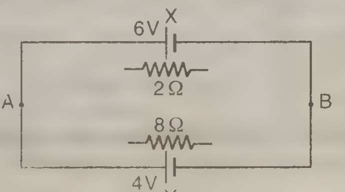
(C) –1 V

(D) +4 V



(C.P.M.T. 1976)

9. The cells X and Y are connected as shown : The potential difference between terminals A and B is



(A) 5·4 V (B) 5·6 V
(C) 5·8 V (D) 6·0 V

10. The instrument for the accurate measurement of the e.m.f. of a cell is
(A) a voltmeter (B) an ammeter
(C) a potentiometer (D) a slide wire bridge.
(Karnataka Entrance, 1993)

11. Potentiometer measures the potential difference more accurately than a voltmeter, because
(A) it has a wire of high resistance
(B) it has a wire of low resistance.
(C) It does not draw current from external circuit
(D) it draws a heavy current from external circuit.
(C.B.S.E. 2002)

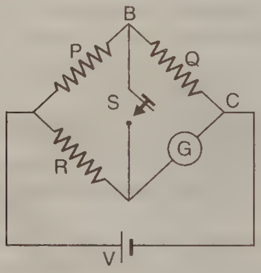
12. The resistivity of potentiometer wire is 10^{-7} Ω m and its area of cross section is 10^{-6} m^2. When a current I = 0·1 A flows through the wire, its potential gradient is
(A) 10^{-2} V m^{-1} (B) 10^{-4} V m^{-1}
(C) 0·1 V m^{-1} (D) 10 V m^{-1} *(C.B.S.E. 2001)*

13. In a potentiometer experiment, for measuring internal resistance of a cell, the balance point has been obtained on fourth wire. The balance point can be shifted to fifth wire by
(A) decreasing the current due to auxiliary battery.
(B) increasing the current due to auxiliary battery.
(C) putting a suitable resistance in series to the cell.
(D) putting a shunt resistance in parallel to the cell.

14. It is observed in a potentiometer experiment that no current passes through the galvanometer, when the terminals of the cell are connected across a certain length of the potentiometer wire. On shunting the cell by a 2 Ω resistance, the balancing length is reduced to half. The internal resistance of the cell is
(A) 4 Ω (B) 2 Ω
(C) 9 Ω (D) 18 Ω

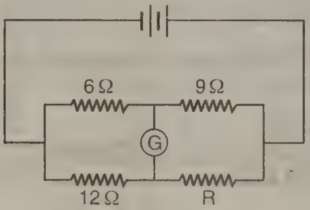
15. The sensitivity of the potentiometer can be increased by :
(A) increasing the e.m.f. of primary cell.
(B) increasing the potential gradient.
(C) increasing the length of potentiometer wire.
(D) decreasing the length of potentiometer wire.
(A.F.M.C. 1998)

16. In the circuit shown in the figure, P≠R. The reading of the galvanometer is same with switch S open or closed. Then,



(A) $I_R = I_G$ (B) $I_P = I_G$
(C) $I_Q = I_G$ (D) $I_Q = I_R$ *(I.I.T. 1999)*

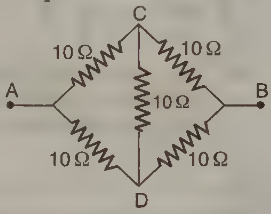
17. When the four resistors are connected as shown, it is found that the current flowing through the galvanometer G is zero. The resistance of R is



(A) 3 ohm (B) 4·5 ohm
(C) 18 ohm
(D) impossible to determine without knowing the e.m.f of the battery. *(Karnataka Entrance, 1988)*

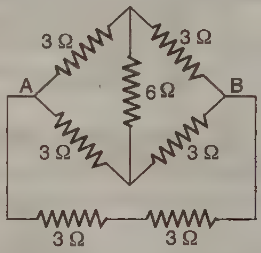
18. In a typical Wheatstone's network, the resistances in cyclic order are P = 10 Ω, Q = 5 Ω, S = 4 Ω and R = 4 Ω. For the bridge to balance,
(A) 10 Ω should be connected in series with P.
(B) 10 Ω should be connected in parallel with P.
(C) 5 Ω should be connected in series with Q.
(D) 5 Ω should be connected in parallel with Q.
(Karnataka, 2000)

19. The effective resistance between points A and B in the given circuit A is



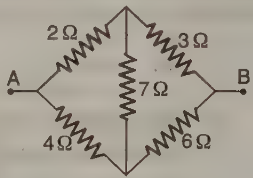
(A) 10 Ω
(B) 20 Ω
(C) 40 Ω
(D) 50 Ω
(C.B.S.E. 2001, N.C.E.R.T. 1974)

20. The resistance of the circuit between points A and B is :



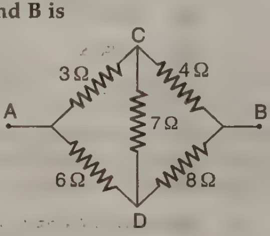
(A) 2 Ω
(B) 18 Ω
(C) 6 Ω
(D) 2·4 Ω

21. Five resistances are connected as shown in the figure. The effective resistance between the points A and B is



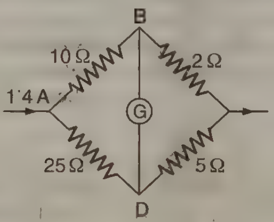
(A) $\frac{10}{3}$ Ω
(B) $\frac{20}{3}$ Ω
(C) 15 Ω
(D) 6 Ω *(I.I.T. 1976)*

22. A bridge circuit is shown in the figure. The equivalent resistance between points A and B is



(A) 21 Ω
(B) 7 Ω
(C) 252/85 Ω
(D) 14/3 Ω *(C.B.S.E. 2000)*

23. In the given circuit, when galvanometer G shows no deflection, the current in the 2 ohm resistor is



(A) 1·4 A
(B) 1·2 A
(C) 1·0 A
(D) 0·4 A
(C.P.M.T. 1989)

24. In a metre bridge, the balancing length from the left end (standard resistance of 1 Ω is in the right gap) is found to be 20 cm. The value of the unknown resistance is

(A) 0·8 Ω (B) 0·5 Ω
(C) 1·4 Ω (D) 0·25 Ω (*C.B.S.E. 1999*)

25. Two resistances are connected in the two gaps of a metre bridge. The balance points is 20 cm from the zero end. When a resistance of 15 ohm is connected in series with the smaller of the two resistances, the null point shifts to 40 cm. The smaller of the two resistances has the value (in ohm)

(A) 8 (B) 9
(C) 10 (D) 12

(*Karnataka Entrance, 1985*)

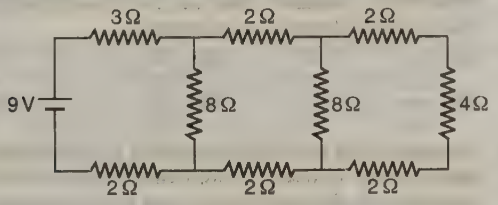
26. An unknown resistance R_1 is connected in series with a resistance of 10 ohm. This combination is connected to one gap of a metre bridge, while other gap is connected to another resistance R_2. The balance point is at 50 cm. Now, when the 10 ohm resistance is removed, the balance point shifts to 40 cm. Then, the value of R_1 (in ohm) is

(A) 60 (B) 40
(C) 20 (D) 10

(*Karnataka Entrance, 1987*)

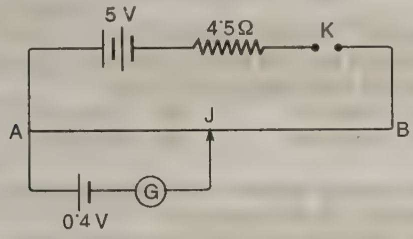
PART II. THOUGHT-BASED QUESTIONS

27. In the circuit shown in the figure, the current through the



(A) 3 Ω resistor is 0·50 A.
(B) 3 Ω resistor is 0·25 A.
(C) 4 Ω resistor is 0·50 A.
(D) 4 Ω resistor is 0·25 A. (*I.I.T. 1998*)

28. In figure, the potentiometer wire AB has a resistance of 5 Ω and length 10 m. The balancing length AJ for the e.m.f. of 0·4 V is



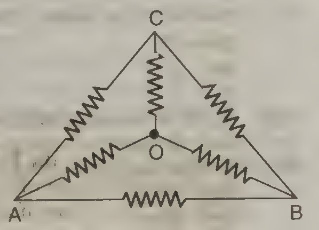
(A) 4 m (B) 1·5 m
(C) 0·8 m (D) 0·4 m (*A.F.M.C. 1995*)

29. When balance point is obtained in a potentiometer for finding the internal resistance of a cell ; the current through the potentiometer wire is due to

(A) the cell, whose internal resistance is to be found.
(B) the auxiliary battery.
(C) both cell and the auxiliary battery.
(D) neither the cell nor the battery.

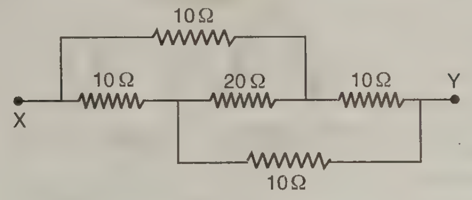
30. Six equal resistances each of 4 Ω are connected to form the following network. The resistance between any two terminals of the network is

(A) 4 Ω
(B) 1 Ω
(C) 2 Ω
(D) 0·5 Ω



31. The equivalent resistance between the points X and Y of the following circuit is

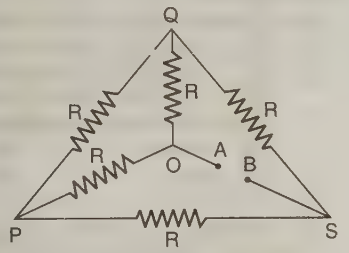
(A) 10 Ω (B) 30 Ω
(C) 20 Ω (D) 50 Ω



(*C.P.M.T. 1988*)

32. Each of resistance in the network shown in the figure is equal to R. The resistance between the terminals A and B is

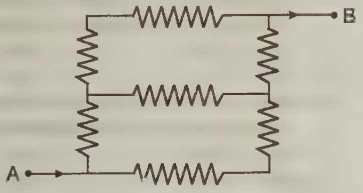
(A) R
(B) 5 R
(C) 3 R
(D) 6 R



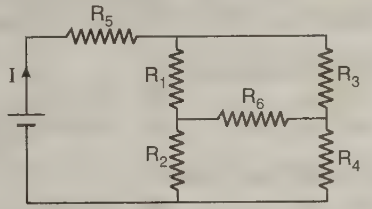
(*C.B.S.E. 1995 ; I.I.T. 1978*)

33. Seven resistances each of 5 Ω are connected as shown in figure. The equivalent resistance between the points A and B is

(A) 5 Ω
(B) 7 Ω
(C) 14 Ω
(D) 35 Ω



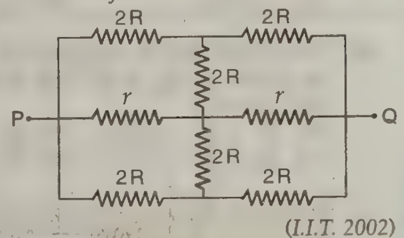
34. In the given ciruit, it is observed that the current I is independent of the value of the resistance R_6. Then the resistance values must satisfy :



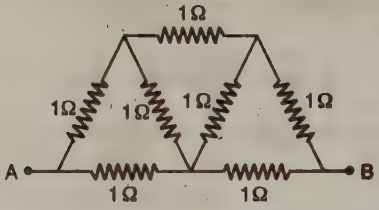
(A) $R_1 R_4 = R_2 R_3$
(B) $R_1 R_3 = R_2 R_4$
(C) $R_1 R_2 R_5 = R_3 R_4 R_6$
(D) $\frac{1}{R_5}+\frac{1}{R_6}=\frac{1}{R_1+R_2}+\frac{1}{R_3+R_4}$ (*I.I.T. 2001*)

35. In the given ciruit, it is observed that the current I is independent of the value of the resistance R_6. Then the registance values must satisfy :

(A) $\frac{2Rr}{R+r}$
(B) $\frac{8R(R+r)}{3R+r}$
(C) $2r+4R$
(D) $2r+5R/2$ (*I.I.T. 2002*)



36. **In the network shown in figure, each resistance is 1 Ω. The effective resistance between the points A and B is**



(A) $\frac{4}{3}\Omega$ (B) $\frac{3}{2}\Omega$
(C) 7 Ω (D) $\frac{8}{7}\Omega$ (C.B.S.E. 1990

Chapter 3. Thermal effects of Current

PART I. TEXT-BASED QUESTIONS

1. **You have the the following electrical appliances :**
(*i*) 1 kW-250 V electric heater
(*ii*) 1 kW-250 V electric kettle
(*iii*) 1 kW-250 V electric bulb
Which of these have highest resistance ?
(A) Heater (B) Kettle
(C) Bulb (D) All have equal resistances.
(*N.C.E.R.T. 1991*)

2. **If a power of 100 W is being supplied across a potential difference of 200 V, current flowing is**
(A) 0·5 A (B) 1 A
(C) 2 A (D) 20 A (*A.F.M.C. 1993*)

3. **A current of 2 A passing through conductor produces 80 J of heat in 10 seconds. The resistance of the conductor is**
(A) 0·5 Ω (B) 2 Ω
(C) 4 Ω (D) 20 Ω (*C.B.S.E. 1993*)

4. **How many calories of heat will approximately be developed in a 210 W electric bulb in 5 minutes.**
(A) 15000 (B) 1050
(C) 63000 (D) 80000 (*M.N.R. 1985*)

5. **Two bulbs 25 W – 220 V and 100 W – 220 V are given. Which has higher resistance ?**
(A) 25 W bulb (B) 100 W bulb
(C) Both bulbs will have equal resistances
(D) Resistances of the bulbs cannot be compared.
(*C.B.S.E. 2000*)

6. **A kilowatt-hour is a unit of**
(A) energy (B) power
(C) electric charge (D) electric current.
(*N.C.E.R.T. 1985*)

7. **One kilowatt hour equals**
(A) 36×10^5 J (B) 36×10^3 J
(C) 36×10^{-5} J (D) 36×10^{-3} J
(*C.B.S.E. 1997 ; N.C.E.R.T. 1974*)

8. **Watt-hour meter measures :**
(A) electrical energy (B) current
(C) voltage (D) power.
(*Karnataka Entrance, 1994*)

9. **A 2 kW boiler used for 1 hour everyday consumes the following electrical energy in thirty days :**
(A) 60 units (B) 120 units
(C) 15 units (D) None of above.
(*Karnataka Entrance, 1993*)

10. **An electric lamp is marked 60 W–230 V. The cost of 1 kWh of electric energy is Rs. 1·25. The cost of using this lamp for 8 hours is :**
(A) Rs. 1·20 (B) Rs. 4·00
(C) Re. 0·25 (D) Re. 0·60.
(*Karnataka Entrance, 1994*)

11. **If current flowing in a conductor changes by 1%, then power will change by**
(A) 1% (B) 2%
(C) 10% (D) 100% (*A.F.M.C. 1996*

12. **A 5 °C rise in temperature is observed in a conductor b passing the current. When the current is doubled, the ris in temperature will be approximately**
(A) 5 °C (B) 10 °C
(C) 20 °C (D) 40 °C (*C.B.S.E. 1998*

13. **If according to Joule's law of heating, the potentia difference across a conductor having a material o resistivity ρ remains constant, then heat produced in th conductor is directly proportional to**
(A) ρ (B) ρ^2
(C) $\frac{1}{\sqrt{\rho}}$ (D) $\frac{1}{\rho}$ (*P.E.T. 1986*

14. **A heater coil is cut into two parts of equal lengths and onl one of them is used in the heater. The ratio of the hea produced by this half coil to that by the original coil is**
(A) 2 : 1 (B) 1 : 2
(C) 1 : 4 (D) 4 : 1

15. **In an ordinary electric heater, if the length of the coil i reduced to half, a given quantity of water will boil in**
(A) more time (B) less time
(C) same time
(D) a time, which depends upon the resistivity of the wir
(*Karnataka Entrance, 199*

16. **On 220 V supply, a heater heats a volume of water i 5 minutes time. On the supply of 110 V, the same heater wi heat the same volume of water in**
(A) 5 minutes (B) 8 minutes
(C) 10 minutes (D) 20 minutes
(*A.F.M.C. 199*

17. **The heating element of a heater should be made with material, which should have**
(A) high resistivity and high melting point.
(B) high resistivity and low melting point.
(C) low resistivity and low melting point.
(D) low resistivity and high melting point.
(*M.N.R. 198*

18. **Two heater wires of equal lengths are first connected i series and then in parallel. The ratio of heat produced i two cases is**
(A) 2 : 1 (B) 1 : 2
(C) 4 : 1 (D) 1 : 4.
(*C.E.T. 1999 ; M.N.R. 198*

19. **If two bulbs, whose resistances are in the ratio of 1 : 2, a connected in series. The power dissipated in them has th ratio of**
(A) 1 : 1 (B) 1 : 2
(C) 2 : 1 (D) 1 : 4 (*C.B.S.E. 199*

20. **A 500 W heating unit is designed to operate from a 115 line. If the line voltage drops to 110, the percentage dro in heat output will be**
(A) 10·2% (B) 8·1%
(C) 8·6% (D) 7·6% (*Dhanbad, 199*

21. A heating coil is labelled 100 W-220 V. The coil is cut in two halves and the two pieces are joined in parallel to the same source. The energy now liberated per second is
(A) 25 J (B) 50 J
(C) 200 J (D) 400 J (C.B.S.E. 1995)

22. Three equal resistors connected across a source of e.m.f. together dissipate 10 W of power. What will be the power dissipated, if the same resistors are connected in parallel across the same source of e.m.f. ?
(A) 5 W (B) 10 W
(C) 30 W (D) 90 W (C.B.S.E. 1998)

23. A 25 W-220 V bulb and a 100 W-220 V bulb are joined in series and connected to the mains. Which bulb will glow brighter ?
(A) 25 W bulb (B) 100 W bulb
(C) First 25 W bulb and then 100 W bulb.
(D) Both will glow with same brightness. *(I.I.T. 1972)*

24. If R_1 and R_2 are respectively the filament resistance of a 200 W bulb and a 100 W bulb designed to operate on the same voltage, then
(A) $R_1 = 2R_2$ (B) $R_2 = 2R_1$
(C) $R_2 = 4R_1$ (D) $R_1 = 4R_2$
(Karnataka Entrance , 1990 ; C.P.M.T. 1990)

25. Of the two bulbs in a house, one glows brighter than the other. Which of the two has a larger resistance ?
(A) The brighter bulb. (B) The dim bulb.
(C) Both have the same resistance.
(D) The brightness does not depend upon the resistance. *(C.P.M.T. 1985)*

26. A fuse is used in an electrical circuit to
(A) indicate the consumption of power.
(B) break the circuit, when the power is off.
(C) maintain constant current.
(D) break the circuit in case of overloading.
(Karnataka Entrance , 1988)

PART II. THOUGHT-BASED QUESTIONS

7. *(i)* The product of volt and coulomb is joule,
(ii) The product of volt and ampere is joule per second.
(iii) The product of volt and watt is horse power.
(iv) Watt-hour can be measured in terms of electron-volt.
(A) All the four are correct.
(B) *(i)*, *(ii)* and *(iv)* are correct.
(C) *(i)* and *(iii)* are correct.
(D) *(iii)* and *(iv)* are correct. *(N.C.E.R.T. 1978)*

28. Two heating coils, one of fine wire and the other of thick wire made of the same material and of the same length, are connected in series and in parallel. Which of the following statement is correct ?
(A) In series, fine wire ; and in parallel, thick wire will liberate more energy.
(B) In series, fine wire will liberate less energy ; while in parallel more energy.
(C) In series, thick wire will liberate more energy ; while in parallel, less energy.
(D) Both will liberate equal energy. *(N.C.E.R.T. 1972)*

29. If two bulbs of wattage 25 and 100 respectively each rated at 220 volt are connected in series with the supply of 440 volt, which bulb will get fused ?
(A) 100-watt bulb (B) 25-watt blub
(C) none of them (D) both of them
(Karnataka Entrance , 1988 ; M.N.R. 1988)

30. If a wire of resistance 20 Ω is covered with ice and a voltage of 210 V is applied across the wire, then the rate of melting of ice is
(A) 6·6 g s^{-1} (B) 4·2 g s^{-1}
(C) 2·1 g s^{-1} (D) 1·1 g s^{-1} *(A.F.M.C. 1997)*

31. Household electrical appliances are not usually connected in series, because
(A) switching off an appliance would switch off the rest.
(B) a fuse would blow, as soon as one appliance is used.
(C) power consumption would be very much greater.
(D) the appliances would get damaged due to high current.
(Karnataka Entrance, 1991)

32. A constant voltage is applied between the two ends of a uniform metallic wire. Some heat is developed in it. The heat developed is doubled, if
(A) both the length and radius of wire are halved.
(B) both length and radius of wire are doubled.
(C) the radius of wire is doubled.
(D) the length of the wire is doubled. *(I.I.T. 1980)*

33. A resistor R_1 dissipates the power P, when connected to certain voltage supply. If a resistor R_2 is put in series with R_1, the power dissipated by R_1
(A) decreases. (B) increases.
(C) remains same.
(D) Any of the above, depending upon the relative values of R_1 and R_2. *(C.P.M.T. 1985)*

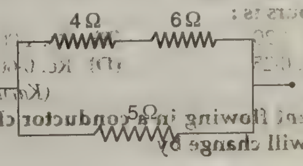
34. Two identical batteries each of e.m.f. E = 2 V and internal resistance $r = 1\ \Omega$ are available to produce heat in an external resistance R = 0·5 Ω by passing a current through it. The maximum Joulean power that can be developed across R using these batteries is
(A) 1·28 W (B) 2·0 W
(C) 8/9 W (D) 3·2 W (C.B.S.E. 1990)

35. A lamp of 6 V and 30 W is used in a laboratory, but the supply is 220 V. For this, following may be done :
(i) A resistance may be used in parallel with the lamp.
(ii) A resistance may be used in series with the lamp.
(iii) The resistance should be of 42·8 Ω.
(A) *(i)*, *(ii)* and *(iii)* (B) *(i)* and *(ii)*
(C) *(i)* and *(iii)* (D) *(ii)* or *(iii)* (N.D.A. 1994)

36. It is well known that the resistance of the filament of an electric bulb changes with temperature. If an electric bulb rated 220 volt-100 watt is connected to a source of voltage 220 × 0·8 volt, then actual power will be
(A) 100 × 0·8 watt. (B) $100 \times (0{\cdot}8)^2$ watt.
(C) more than 100 × 0·8 watt, but less than 100 watt.
(D) more than $100 \times (0{\cdot}8)^2$ watt, but less than 100 × 0·8 watt.
(C.P.M.T. 1989)

37. You are given resistance wire of length 50 cm and a battery of negligible resistance. In which case, the maximum amount of heat is generated ?
(A) When the wire is connected across the battery directly.
(B) When the wire is divided into two parts and both the parts are connected across the battery in parallel.
(C) When the wire is divided into four parts and all the four parts are connected across the battery in parallel.
(D) When only half the wire is connected across the battery.
(N.C.E.R.T. 1974)

38. In the circuit as shown in figure, the heat produced in the 5 Ω resistor due to the current flowing in it is 10 cal s^{-1}. The heat generated in 4 Ω is



(A) 1 cal s^{-1} (B) 2 cal s^{-1}
(C) 3 cal s^{-1} (D) 4 cal s^{-1} *(I.I.T. 1985)*

39. A battery of emf 10 V and internal resistance 0·5 ohm is connected across a variable resistance R. The value of R, for which the power delivered in it is maximum, is given by *(C.B.S.E. 1992)*
(A) 2·0 ohm (B) 0·25 ohm
(C) 1·0 ohm (D) 0·5 ohm

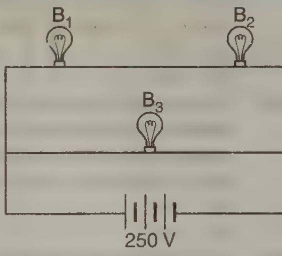
40. A factory is served by a 220 V power supply line. In a circuit protected by a fuse marked 10 A, the maximum number of 100 W lamps in parallel that can be turned on is
(A) 11 (B) 22
(C) 31 (D) 45 *(C.E.T. 1998)*

41. What is immaterial for an electric fuse ?
(A) Its specific resistance
(B) Its radius
(C) Its length
(D) Current flowing through it
(E) None of above. *(M.N.R. 1985)*

42. A fuse wire with a radius of 1 mm blows at 1·5 A. If the fuse wire of the same material should blow at 3·0 A, the radius of the wire must be
(A) $4^{1/3}$ mm (B) 2 mm
(C) 0·5 mm (D) 8·0 mm
(Karnataka Entrance , 1991)

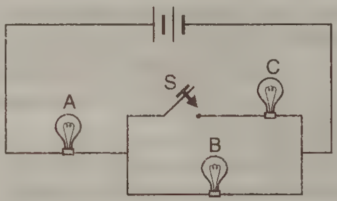
43. Forty electric bulbs are connected in series across a 220 V supply. After one bulb gets fused, the remaining thirty nine bulbs are again connected in series across the same supply. The illumination will be
(A) equal in both the cases.
(B) more with 40 bulbs than with 39.
(C) more with 39 bulbs than with 40.
(D) in the ratio $40^2 : 39^2$.

44. A 100 W bulb B_1, and two 60 W bulbs B_2 and B_3, are connected to a 250 V source as shown in the figure. Now W_1, W_2 and W_3 are the output powers of the bulbs B_1, E and B_3 respectively. Then



(A) $W_1 > W_2 = W_3$
(B) $W_1 > W_2 > W_3$
(C) $W_1 < W_2 = W_3$
(D) $W_1 < W_2 < W_3$

45. Three identical electric bulbs A, B and C are connected a shown :



What changes occur in brightness of the bulbs, when th switch is closed ?
(A) Brightness of A increases, but that of B decreases.
(B) Brightness of A remains the same, but that of decreases.
(C) Brightness of both A and B decreases.
(D) Brightness of A increases, but that of B remains th same.

46. If 2·2 kW power is transmitted through a 10 Ω line a 22,000 V, the power loss in the form of heat will be
(A) 0·1 W (B) 1 W
(C) 10 W (D) 100 W *(M.P. 199*

Chapter 4. Chemical effects of Current

PART I. TEXT-BASED QUESTIONS

1. A voltameter is an instrument
(A) to measure the potential difference.
(B) to determine the electrochemical equivalent.
(C) to find the electrical power.
(D) made up of a pile of voltmeters.
(Karnataka Entrance, 1993)

2. In an electrolyte, electric conduction is due to the flow of :
(A) electrons (B) negative ions only
(C) positive ions only
(D) both the negative and positive ions.

3. When current is passed through water voltameter, hydrogen is liberated at :
(A) anode (B) cathode
(C) escapes to atmosphere
(D) remains in water.

4. When a current is passed through water acidified with a dilute sulphuric acid, the gases formed at the platinum electrodes are :
(A) 1 volume hydrogen (cathode) and 2 volume oxygen (anode)
(B) 2 volume hydrogen (cathode) and 1 volume oxygen (anode)
(C) 1 volume hydrogen (cathode) and 1 volume oxygen (anode)
(D) 1 volume oxygen (cathode) and 2 volume hydrogen (anode) *(Karnataka Entrance, 1994)*

5. Copper sulphate solution has a direct current passe through it using platinum electrodes. The substance liberated at the electrode are :
(A) oxygen at anode and hydrogen at cathode.
(B) hydrogen at anode and oxygen at cathode.
(C) hydrogen at anode and copper at cathode.
(D) oxygen at anode and copper at cathode.

6. The current inside a copper voltameter
(A) is half the outside value.
(B) is the same as the outside value.
(C) is twice the outside value.
(D) depends on the concentration of $CuSO_4$.
(Roorkee, 199

7. The electrochemical equivalent of a metal is $3{\cdot}3 \times 10$ kg C^{-1}. The mass of the metal liberated at the cathod when a 3 A current is passed for 2 s will be :
(A) $1{\cdot}1 \times 10^{-7}$ kg (B) $6{\cdot}6 \times 10^{-7}$ kg
(C) $9{\cdot}9 \times 10^{-7}$ kg (D) $19{\cdot}8 \times 10^{-7}$ kg
(S.C.R.A. 199

8. If nearly 10^5 C of charge liberates 1 gram equivalent o aluminium, then the amount of aluminium (equivaler weight = 9) is deposited through electrolysis in 20 min b a current of 50 A will be
(A) 0·6 g (B) 1·8 g
(C) 5·4 g (D) 10·8 g *(C.B.S.E. 199*

9. In an electroplating experiment, *m* gram of silver deposited, when 4 ampere of current flows for 2 minute

The amount (in gram) of silver deposited by 6 ampere of current flowing for 40 seconds will be

(A) 4 m (B) $m / 2$
(C) $m / 4$ (D) 2 m *(M.N.R. 1991)*

10. **In producing chlorine through the process of electrolysis, 100 kW power at 125 V is being consumed. E.C.E. for chlorine = $0{\cdot}367 \times 10^{-6}$ kg C^{-1}. How much chlorine per minute is being liberated ?**
(A) 367 g (B) 3·67 g
(C) 17·6 g (D) 18·6

11. **A current passing through a copper voltameter deposits 0·002 kg of copper on the cathode plate in 100 minutes. If there are 10^{25} atoms in 1 kg of copper, the electric charge delivered to the cathode by Cu^{++} ions per second will be**
(A) 0·53 C (B) 0·71 C
(C) 1·06 C (D) 10·06 C *(A.M.U. 1999)*

12. **In view of chemical effect of electricity, Faraday constant is equal to the ratio of**
(A) electrochemical equivalent to the chemical equivalent.
(B) electrochemical equivalent to the gram equivalent.
(C) gram equivalent to the electrochemical equivalent.
(D) chemical equivalent to the electrochemical equivalent. *(S.C.R.A. 1994)*

3. **In electrolysis, the mass deposited on an electrode is directly proportional to**
(A) current (B) square of current
(C) concentration of solution
(D) inverse of current. *(C.B.S.E. 2000)*

14. **The masses of different substances liberated in electrolysis by the same quantity of electricity are proportional to their :**
(A) atomic masses.
(B) ratios of the atomic mass and valency.
(C) valencies.
(D) products of atomic mass and valency.

5. **Silver and zinc voltameters are connected in series and a current is passed through them for time *t*. If the mass of zinc liberated is *m*, the mass of silver deposited would be nearly**
(A) m (B) 1·7 m
(C) 2·4 m (D) 3·3 m *(N.C.E.R.T. 1976)*

6. **A copper voltameter and silver voltameter are connected in series in a circuit. The rate of the increase in the weights of the cathodes in the two voltameters will be :**
(A) in the ratio of the densities of Cu and Ag.
(B) in the ratio of the atomic weights of Cu and Ag.
(C) in the ratio of half the atomic weight of Ag to the atomic weight of Cu.
(D) in the ratio of half the atomic weight of Cu to the atomic weight of Ag.

7. **Faraday constant F, Avogadro number N and electronic charge *e* are related with each other by :**
(A) $F = \frac{N}{e}$ (B) $F = \frac{e}{N}$
(C) $F = N e$ (D) $F = N e^2$

18. **On passing a charge of 2 faraday through a copper voltameter, the mass of copper ions liberated will be :**
(A) 128 g (B) 16 g
(C) 32 g (D) 64 g

19. **The commercial aluminium (trivalent, atomic weight=27) is generally obtained by electrolysis. The total charge required (1 faraday = 96500 C) to deposit 9 g of aluminium is :**
(A) 3266·6 C (B) 96500 C
(C) 65900 C (D) 289·5 C *(M.N.R. 1982)*

20. **Electroplating does not help metals to**
(A) give fine finish to the surface.
(B) give shining appearance.
(C) become hard.
(D) to protect against corrision. *(A.I.I.M.S. 1998)*

21. **Which of the following statements is not correct ?**
(A) In a voltaic cell, the anode and cathode are copper and zinc rod respectively.
(B) Leclanche cell suffers from polarisation.
(C) Dry cell is basically a lechanche cell.
(D) Edison alkali cell is a primary cell.

22. **The equation**
$$Zn + 2\,NH_4Cl \longrightarrow 2\,NH_3 + ZnCl_2 + 2\,H + 2\,e$$
represents the :
(A) dry cell (B) Daniel cell
(C) Leclanche cell (D) none of these. *(A.I.I.M.S. 1988)*

23. **Which of the following statements is not correct ?**
(A) A primary cell is an electrochemical cell.
(B) After charging, a primary cell can be again put to use.
(C) Dry cell is a primary cell.
(D) Leclanche cell is used in experiments, where constant supply of current is not needed.

24. **The efficiency of a modern accumulator is of the order of :**
(A) 100% (B) 70%
(C) 50% (D) 33%

PART II. THOUGHT-BASED QUESTIONS

25. **The E.C.E. of a substance is equal to the product of its chemical equivalent and the E.C.E. of :**
(A) oxygen (B) hydrogen
(C) copper (D) platinum

26. **How much electricity must pass through acidulated water to release 22,400 cm^3 of hydrogen at N.T.P. ?**
(A) 96500 C (B) 193000 C
(C) 22·4 C (D) 95·5 C

27. **The electric charge for electrode deposition of one gram equivalent of substance is**
(A) one ampere per second.
(B) 96500 coulomb per second.
(C) one ampere per hour.
(D) charge on one mole electron. *(I.I.T. 1984)*

28. **In a lead accumulator, the plates are placed close to each other ; as**
(A) it makes the lead accumulator sturdy.
(B) it increases the e.m.f. of the accumulator.
(C) it decreases the internal resistance of the accumulator.
(D) it increases the life span of the accumulator.

29. **Which of the following statements is not correct ? A lead accumulator of 20 ampere-hour can supply :**
(A) 20 A current for 20 hours.
(B) 1 A current for 20 hours.
(C) 20 A current for 1 hour.
(D) 0·1 A current for 200 hours.

Chapter 5. Thermoelectric effect

RT I. TEXT-BASED QUESTIONS

1. **When current flows through a conductor, heat is produced. This is**
(A) Seebeck effect (B) Thomson effect
(C) Peltier effect (D) Joule effect

2. **Which of the following statements is correct ? The thermo e.m.f. of a thermocouple :**
(A) is independent of the nature of the pair of metals used.
(B) depends upon the temperature of cold junction alone.
(C) depends upon the temperature of hot junction alone.
(D) depends upon the temperature of cold junction and the

3. For a thermocouple, the thermo e.m.f. may be:
(A) zero (B) positive
(C) negative (D) any of the above.

4. As the temperature of hot junction is increased, the thermo-e.m.f. produced :
(A) is always positive.
(B) may be positive or negative.
(C) always increases with temperature.
(D) first increases with temperature and then decreases, but never becomes negative.

5. The temperature of a hot junction, at which the thermo-e.m.f. is maximum, is
(A) neutral temperature.
(B) transitional temperature.
(C) temperature of inversion.
(D) null temperature. *(Karnataka Entrance, 1984)*

6. Above neutral temperature, thermo-e.m.f. :
(A) changes sign. (B) is constant.
(C) increases with rise in temperature.
(D) decreases with rise in temperature.

7. The thermoelectric power is the rate of change of thermo-e.m.f. with
(A) temperature (B) time
(C) resistance (D) current.
(Karnataka Entrance, 1990)

8. The thermo e.m.f. E (in volt) of a certain thermocouple is found to vary with temperature θ (in °C) in accordance with the relation,

$$E = 40\,\theta = \frac{\theta^2}{20},$$

where θ is the temperature of the hot junction, the cold junction being kept at 0°C. The neutral temperature of thermocouple is
(A) 100°C (B) 200°C
(C) 300°C (D) 400°C

9. A thermopile is a number of thermocouples connected in
(A) series (B) parallel
(C) either series or parallel
(D) both series and parallel. *(Karnataka Entrance , 1989)*

10. Thermopile is used for :
(A) measuring the e.m.f.
(B) measuring the current.
(C) converting heat energy into electrical energy.
(D) measuring and detecting the heat radiation.

11. When different parts of a metal are kept at different temperatures and current is passed through it, the heat is either evolved or absorbed. This effect is called
(A) Peltier effect (B) Seebeck effect
(C) Thomson effect (D) none of the above.

PART II. THOUGHT-BASED QUESTIONS

12. The respective temperature of cold and hot junctions of Sb-Bi and a Cu-Fe thermocouples are same. If E_1 and E_2 a thermo-e.m.f. developed in the two cases, then :
(A) $E_1 = E_2$ (B) $E_1 < E_2$
(C) $E_1 > E_2$ (D) cannot be predicted.

13. A copper wire AB and an iron wire AC are joined at A. T junction A is kept at 0°C and the free ends of t arrangement of the two wires are maintained at 100° Then, a potential difference exists between
(A) the two ends of the copper wire.
(B) the two ends of the iron wire.
(C) the free ends of the arrangement of two wires.
(D) the ends of the two wires forming the junction.

14. At the temperature of inversion, thermo-electric current a Cu-Fe thermocouple
(A) flows from Cu to Fe through hot junction.
(B) flows from Fe to Cu through hot junction.
(C) is maximum.
(D) does not depend upon the temperature of cold junctic

15. The plot showing the variation of thermo-e.m.f. wi temperature of the hot junction of a thermocouple is
(A) parabolic (B) circular
(C) hyperbolic (D) elliptical.

16. The cold junction of a silver-lead thermocouple is kept 0°C. If the values of constants α and β for the thermocoup are 2·50 μV °C^{-1} and 0·012 μV °C^{-2} respectively, then increasing the temperature of the other junction,
(A) no thermo-e.m.f. will be produced.
(B) no thermoelectric current will be produced.
(C) no neutral temperature will be obtained.
(D) no inversion temperature will be obtained.

17. In a certain range of temperature, a copper-constant thermocouple produces a thermo-e.m.f. of 40 μV °C^{-1}. galvanometer of resistance 10 Ω and capable of detecti current of the order of 1 μA is used to measure t temperature. What is the smallest temperature that c be measured by the galvanometer ?
(A) $\frac{1}{400}$°C (B) $\frac{1}{4}$°C
(C) 4 °C (D) 400 °C

CHAPTER 1

Magnetic Effect of Current

1.01. CONCEPT OF MAGNETIC FIELD

The space aound a current carrying conductor, in which its magnetic effect can be xperienced, is called magnetic field.

When current is passed through a conductor, it modifies the space around the onductor. If a magnetic pole[*] is placed at a point near the conductor, the magnetic ole experiences force due to the current carrying conductor. The force between the nagnetic pole and the current carrying conductor may be visualised as a two-step rocess. The current through the conductor produces something, called ***magnetic eld***, in the space around the conductor and this magnetic field exerts a force on ny magnetic pole placed in the field. The magnetic field has its own existence and s present even if there is no magnetic pole to experience the force. The magnetic eld due to a current carrying conductor falls off inversely as the distance from the onductor.

The electric and magnetic fields differ from each other on the following ccounts :

1. Whereas the source of electric field is electric charge (a scalar quantity), the ource of magnetic field is current element (a vector quantity). To elaborate, the ource of magnetic field is not a magnetic charge, the analogue of electric charge. is because, an isolated magnetic pole does not exist.

2. Further, there is a qualitative difference between the lines of electric field due a charge distribution with net charge and the lines of magnetic field due to a urrent distribution. Whereas the lines of electric field due to a charge distribution tart from one point and end at some other point, the lines of magnetic field due a current element start and end at the same point *i.e.* they form closed loops.

Quotable Quote

"I have little to say on M. Oersted's discovery, for I must confess I do not quite understand it."

– Michael Faraday

Watch out !

The source of electric field is electric charge. Since an isolated magnetic pole does not exist, source of magnetic field is not a magnetic charge (analogue of electric charge) !

1.02. OERSTED'S EXPERIMENT

In 1820, the Danish scientist Oersted discovered the magnetic effect of electric urrent.

Oersted found that when a wire AB carrying current was held over a magnetic eedle NS, such that electric current passed from the end A of the wire to the end [Fig. 1.01], the north pole of the needle got deflected towards west (into the paper). n holding the wire below the magnetic needle, the north pole of the needle got eflected in the opposite direction. It indicated that magnetic lines of force below nd above the needle are directed in the opposite directions. Thus, Oersted's xperiment led to the discovery that when electric current passes through a onductor, magnetic field is produced around it. If a strong current is passed through conductor, then magnetic field produced around the conductor is also very strong nd the earth's magnetic field may be neglected in its comparison. In such a case, nagnetic lines of force near the conductor are found to be circular. The direction of nagnetic field lines due to a straight current carrying conductor may be found by pplying ***right hand thumb rule*** or ***Maxwell's cork screw rule***[†].

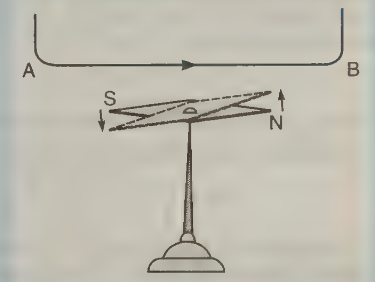

Fig. 1.01

When electric current is passed through a circular conductor, the magnetic field nes near the centre of the conductor are almost straight. The direction of magnetic eld lines may be found by applying ***right hand fist rule.***

1.03. BIOT SAVART'S LAW

Biot Savart's law is a basic law of electricity and magnetism. It is used to find ne magnetic field at a point due to a current carrying conductor.

---

[*] Till today, an isolated pole (or magnetic monopole) has not been detected.

[†] For discussion of the rules, refer to section 1.04.

It states that the magnetic field produced due to a small conductor of length *dl* carrying a current I at a point at distance *r* is given by

$$dB = \frac{\mu_0}{4\pi} \cdot \frac{I\, dl \sin\theta}{r^2},$$

where θ is the angle between the direction of flow of current and the line joining the small conductor to the observation point.

Consider a conductor XY, through which current I is flowing [Fig. 1.02]. Due to flow of current, a magnetic field is produced around the conductor XY. Suppose that we have to find magnetic field at point P due to the current flowing through the conductor XY. Consider a small elementary portion AB = *dl* of the conductor. Let *r* be the distance of the observation point P (the point, at which strength of magnetic field is to be found) from the centre C of the elementary portion AB. Biot and Savart found that the small magnetic field produced at point P due to current flowing through the elementary portion AB is

(*i*) *directly proportional to the current i.e.*

$$dB \propto I$$

(*ii*) *directly proportional to the length of the elementary portion i.e.*

$$dB \propto dl$$

(*iii*) *directly proportional to sine of the angle θ between the direction of the flow of current and the line joining the elementary portion to the observation point i.e.*

$$dB \propto \sin\theta$$

It may be noted that for all the points along the length of the current element, θ = 0 and hence at such points, *d*B = 0. Further, for all points lying in a plane to which the current element is perpendicular, θ = 90° and hence at points at a given distance in this plane, the magnetic field *d*B is maximum.

(*iv*) *inversely proportional to the square of the distance r of the point P from the elementary portion i.e.*

$$dB \propto \frac{1}{r^2}$$

It is known as ***inverse square law.***

Combining all the above factors, we have

$$dB \propto \frac{I\, dl \sin\theta}{r^2}$$

or

$$dB = \frac{k\, I\, dl \sin\theta}{r^2}, \qquad \text{...(1.01)}$$

where *k* is the constant of proportionality. Its value depends upon the nature of medium between the observation point and the current carrying conductor and the system of units used to measure the quantities involved. If the conductor and the observation point lie in vacuum, then in SI,

$$k = \frac{\mu_0}{4\pi} = 10^{-7}\ \mathrm{T\,A^{-1}\,m} = 10^{-7}\ \mathrm{Wb\,A^{-1}\,m^{-1}} \quad (\because 1\,\mathrm{T} = 1\,\mathrm{Wb\,m^{-2}})$$

Here, μ_0 is called ***absolute permeability*** of vacuum or free space.

Therefore, in SI, Biot Savart's law may be expressed as

$$dB = \frac{\mu_0}{4\pi} \cdot \frac{I\, dl \sin\theta}{r^2} \qquad \text{...(1.02)}$$

The equation (1.02) gives the magnitude of the magnetic field produced due to a small current element. When the current flows through the elementary portion AB in the direction as shown in Fig. 1.01, the magnetic field at point P is directed perpendicular to the plane of paper and in inward direction.

The direction of magnetic field produced can be known easily by expressing Biot Savart's law in vector form. If $\hat{r}$ is a unit vector along CP, then the small magnetic field (both in magnitude and direction) produced at point P is given by

$$\vec{dB} = \frac{\mu_0}{4\pi} \cdot \frac{I\,\vec{dl} \times \hat{r}}{r^2} \qquad \text{...(1.03)}$$

Here, $I\,\vec{dl}$ is taken as a vector in the direction of flow of current.

If $\overrightarrow{CP} = \vec{r}$, then the above result may be expressed as

$$\vec{dB} = \frac{\mu_0}{4\pi} \cdot \frac{I\,\vec{dl} \times \vec{r}}{r^3} \qquad \text{...(1.04)}$$

The jargon .....

Biot Savart's law is also known as Laplace's law.

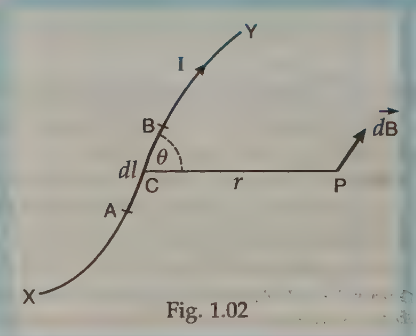

Fig. 1.02

Self-test Question ?

When the observation point lies along the length of the current element $I\vec{dl}$, magnetic field is zero. On the other hand, for a given distance from the current element, field is maximum, when the observation point is located along a direction perpendicular to it. Why ?

Self-test Question ?

Show that in terms of current density $\vec{j}$, equation (1.04) may be expressed as

$$\vec{dB} = \frac{\mu_0}{4\pi} \cdot \frac{\vec{j} \times \vec{r}}{r^3}\, dV$$

The magnetic field due to the whole conductor XY is obtained by integrating $\vec{dB}$ over the entire length of the conductor *i.e.* magnetic field due to the whole conductor at the point P is given by

$$\vec{B} = \int \vec{dB} = \frac{\mu_0}{4\pi} \int \frac{I\,\vec{dl} \times \hat{r}}{r^2} \qquad ...(1.05)$$

The integral in the above equation can be evaluated by knowing the proper limits of the problem.

Direction of $\vec{dB}$. The direction of $\vec{dB}$ is same as that of the vector $I\,\vec{dl} \times \hat{r}$. It follows that at point P, the vector $\vec{dB}$ *is perpendicular to the plane of the paper and is directed inwards.*

1.04. RULES TO FIND DIRECTION OF MAGNETIC FIELD

The direction of magnetic field due to a current carrying conductor can be found by applying the following two rules :

Right hand thumb rule. *If we grasp the conductor in the palm of the right hand so that the thumb points in the direction of the flow of current, then the direction in which the fingers curl, gives the direction of magnetic field lines.* This rule is illustrated in Fig. 1.03.

It follows that magnetic field is in the form of concentric circles, whose centres lie on the straight conductor.

Maxwell's cork screw rule. *If a right handed cork screw is rotated so that it moves in the direction of flow of current through the conductor, then the direction of the rotation of the screw gives the direction of magnetic field lines.* This rule is illustrated in Fig. 1.04.

For the current flowing through the conductor in the direction shown in Figs. 1.03 or 1.04, both the rules predict that magnetic field lines will be in anticlockwise direction, when seen from above.

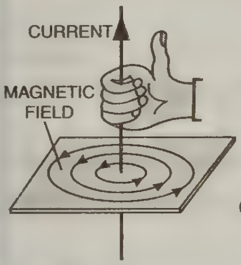

Fig. 1.03

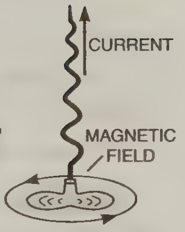

Fig. 1.04

1.05. MAGNETIC FIELD DUE TO CURRENT FLOWING IN A STRAIGHT CONDUCTOR

Consider a long straight conductor XY, through which current I is flowing from the ends X to Y as shown in Fig. 1.05. Then, magnetic field will be set up around the conductor. Suppose that we want to find magnetic field at point P, which is located at a perpendicular distance PM = a from the conductor. To do so, consider an infinitesimally small portion AB of length dl. Suppose that PA = r and $\angle$ PAM = θ. Then, according to Biot-Savart's law, strength of magnetic field at point P due to small portion AB is given by

$$\vec{dB} = \frac{\mu_0}{4\pi} \cdot \frac{I\,\vec{dl} \times \hat{r}}{r^2},$$

where $I\,\vec{dl}$ is a vector in the direction of flow of current and $\hat{r}$ is a unit vector along AP. The direction of magnetic field $\vec{dB}$ at point P due to the small current element AB points in the direction $I\,\vec{dl} \times \hat{r}$ *i.e.* perpendicular to the plane of the paper and in inward direction. The magnitude of the small magnetic field at point P due to current element AB is given by

$$dB = \frac{\mu_0}{4\pi} \cdot \frac{I\,dl \sin\theta}{r^2} \qquad ...(1.06)$$

Since the element AB is infinitesimally small, practically $\angle$ PBM = $\angle$ PAM = θ. Drop AN perpendicular to BP. Then, from right angled triangle ABN, we have

$$AN = dl \sin\theta \qquad ...(1.07)$$

Let $\angle$ MPA = ϕ and $\angle$ APB = $d\phi$. Then,

$$AN = r\,d\phi \qquad ...(1.08)$$

From equations (1.07) and (1.08), we have

$$dl \sin\theta = r\,d\phi$$

Substituting for $dl \sin\theta$ in equation (1.05), we have

$$dB = \frac{\mu_0}{4\pi} \cdot \frac{I\,(r\,d\phi)}{r^2} = \frac{\mu_0}{4\pi} \cdot \frac{I\,d\phi}{r} \qquad ...(1.09)$$

From right angled triangle AMP, we have

$$\cos\phi = \frac{a}{r} \quad \text{or} \quad r = \frac{a}{\cos\phi}$$

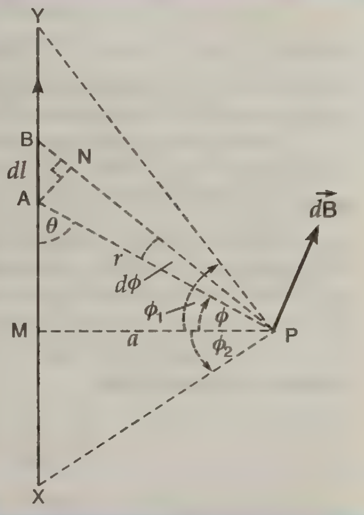

Fig. 1.05

Substituting for r in equation (1.09), we have

$$dB = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \cos\phi \, d\phi$$

Join PX and PY. Let $\angle$ MPY $= \phi_1$ (in clockwise direction) and $\angle$ MPX $= -\phi_2$ (in anticlockwise direction). Then, magnetic field due to the whole length of the conductor can be found by integrating dB given by the above equation within limits $-\phi_2$ to ϕ_1. Thus, the magnetic field due to current flowing through the whole conductor XY,

$$B = \int_{-\phi_2}^{\phi_1} dB = \int_{-\phi_2}^{\phi_1} \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \cos\phi \, d\phi = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \int_{-\phi_2}^{\phi_1} \cos\phi \, d\phi$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \left| \sin\phi \right|_{-\phi_2}^{\phi_1} = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \left| \sin\phi_1 - \sin(-\phi_2) \right|$$

or $$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} (\sin\phi_1 + \sin\phi_2) \qquad \text{...(1.10)}$$

It gives the magnetic field due to a current carrying straight conductor of finite length.

Self-test Question

Show that magnetic field due to a
infinitely long current carrying conducto
at a point near its one end is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a}$$

Special case. If the conductor is infinitely long, then $\phi_1 = \phi_2 = \frac{\pi}{2}$. Hence, the magnetic field at point P due to current flowing through an infinitely long conductor is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \left(\sin\frac{\pi}{2} + \sin\frac{\pi}{2} \right)$$

or $$B = \frac{\mu_0}{4\pi} \cdot \frac{2I}{a} \qquad \text{...(1.11)}$$

The direction of magnetic field is determined by the cross product of the vector $I\vec{dl}$ and $\hat{r}$ *i.e.* by $I\vec{dl} \times \hat{r}$, where $\hat{r}$ is a unit vector along AP. Therefore, at point P, the direction of magnetic field due to the small current element or due to the whole conductor will be along perpendicular to the plane of paper and in inward direction.

The direction of the magnetic field can also be found by making use of the right hand thumb rule or Maxwell's cork screw rule described in section 1.04.

1.06. MAGNETIC FIELD AT THE CENTRE OF A CIRCULAR LOOP

Consider a circular loop of radius a, centre O and carrying current I as shown in Fig. 1.06. In order to find magnetic field at point O, the centre of the loop, consider an infinitesimally small length AB = dl of the loop. Join the centre O of the loop to the middle point C of the current element AB. Obviously, $\angle$ACO is equal to 90°.

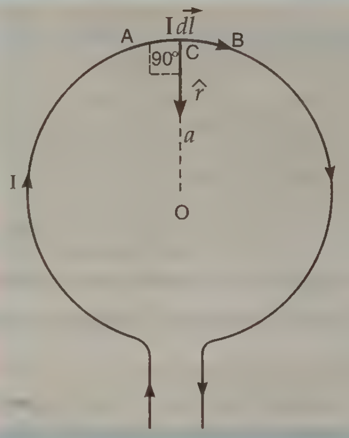

Fig. 1.06

According to Biot-Savart's law, the magnetic field at point O due to the current element AB is given by

$$\vec{dB} = \frac{\mu_0}{4\pi} \cdot \frac{I\vec{dl} \times \hat{r}}{a^2},$$

where $I\vec{dl} = I(\vec{AB})$ is a vector in the direction of flow of current through AB and $\hat{r}$ is a unit vector along CO. The magnetic field $\vec{dB}$ at point O due to the small current element AB points in the direction of $I\vec{dl} \times \hat{r}$ *i.e.* perpendicular to the plane of the loop and in inward direction. Since angle between $I\vec{dl}$ and $\hat{r}$ is 90°, the magnitude of magnetic field at point O due to the current element AB is given by

$$dB = \frac{\mu_0}{4\pi} \cdot \frac{I\,dl}{a^2}$$

Hence, the magnetic field at point O due to the whole circular loop is given by

$$B = \oint dB = \oint \frac{\mu_0}{4\pi} \cdot \frac{I\,dl}{a^2} = \frac{\mu_0}{4\pi} \cdot \frac{I}{a^2} \oint dl$$

Now, $\oint dl =$ circumference of the loop $= 2\pi a$

Key point

When current I flows through tw
concentric circular conductors of radii a
and a_2, net magnetic field at their centr
is given by

$$B = \frac{\mu_0}{4\pi} \cdot I \left(\frac{1}{a_1} + \frac{1}{a_2} \right),$$

when current flows in same direction an
by the relation

$$B = \frac{\mu_0}{4\pi} \cdot I \left(\frac{1}{a_1} - \frac{1}{a_2} \right),$$

when current flows in opposite directio
through the two circular conductors.

Therefore,
$$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a^2} (2\pi a)$$

or
$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{a} \qquad ...(1.12)$$

In case the circular loop has n turns, then
$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} \qquad ...(1.13)$$

Direction of magnetic field. The whole circular loop may be supposed to be divided into a large number of current elements, such as AB. Since the direction of magnetic field produced at point O due to each current element is same, the magnetic field due to whole of the circular loop will be same as that due to the current element AB *i.e.* magnetic field B will be perpendicular to the plane of the loop and in inward direction. In general, if current through a loop flows in clockwise direction, then direction of magnetic field at its centre is perpendicular to the plane of the loop and in inward direction. On the other hand, if the current flows through the loop in anticlockwise direction, then direction of magnetic field at its centre is perpendicular to the plane of the loop and in outward direction.

Self-test Question ?

Show that magnetic field due to a part of current carrying circular conductor is
$$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a}\,\theta,$$
where θ is angle, which the circular part subtends at its centre.

Key point ✓

Magnetic field due to a current carrying circular conductor is non-uniform. However, it may be considered as uniform (for practical purposes) at its centre.

Fig. 1.08 explains a useful method to know the direction of the magnetic field, when the current flows through a circular loop. The face of the loop, in which the current appears to flow anticlockwise [Fig. 1.07 (*a*)], acts as magnetic north pole. On the other hand, if the current appears to flow through the face of the loop in clockwise direction [Fig. 1.07 (*b*)], then the face acts as magnetic south pole. In both the cases, the magnetic field at the centre of the loop is directed along normal to the plane of the loop.

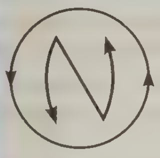

Fig. 1.07 (*a*)

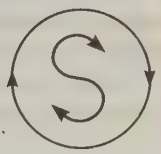

Fig. 1.07 (*b*)

1.07. MAGNETIC FIELD AT A POINT ONTHE AXIS OF A LOOP

Consider a circular loop of radius a, centre O and carrying a current I as shown in Fig. 1.08. The plane of the loop (YZ-plane) is perpendicular to the plane of the paper, while the axis of the loop (*i.e.* OX or X-axis) lies in the plane of the paper.

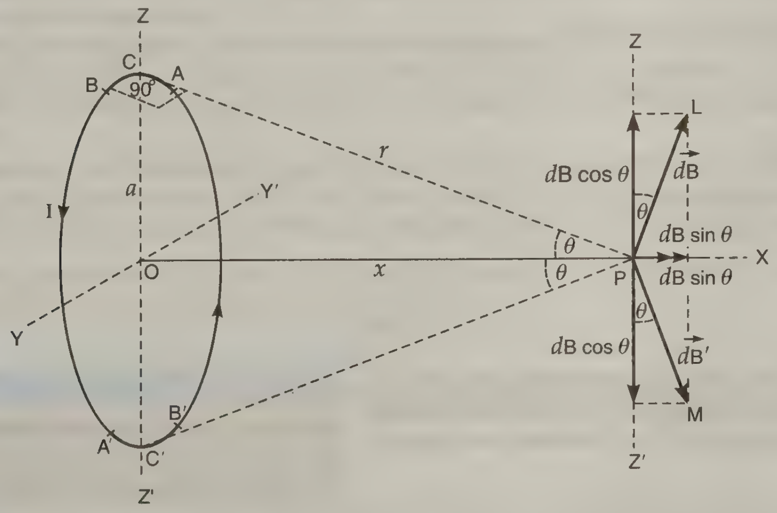

Fig. 1.08

Let P be the point on the axis of the loop at a distance OP = x from its centre O, where the magnetic field due to the circular loop has to be determined. In order to do so, consider an infinitesimally small length AB = dl of the loop. Join the point P to the middle point C of the current element AB. Suppose that CP = r. Obviously, ∠ BCP (or ∠ ACP) is equal to 90°.

According to Biot Savart's law, the magnetic field due to the current element AB at point P is given by
$$\vec{dB} = \frac{\mu_0}{4\pi} \cdot \frac{I\,\vec{dl} \times \hat{r}}{r^2},$$
where $I\,\vec{dl} = I\,(\overrightarrow{AB})$ is a vector in the direction of flow of current through AB and $\hat{r}$ is a unit vector along CP. The magnetic field $\vec{dB}$ at point P due to the small current

element AB points in the direction of vector $\mathrm{I}\,\overrightarrow{dl} \times \hat{r}$ and it has been represented by the vector $\overrightarrow{\mathrm{PL}}$. As the angle between $\mathrm{I}\,\overrightarrow{dl}$ and $\hat{r}$ is 90°, the magnitude of $\overrightarrow{d\mathrm{B}}$ is given by

$$d\mathrm{B} = \frac{\mu_0}{4\pi} \cdot \frac{\mathrm{I}\,dl}{r^2} \qquad \text{...(1.14)}$$

Let us consider the small element A′B′ = dl located just opposite to the element AB. The magnetic field $\overrightarrow{d\mathrm{B}'}$ due to the current element A′B′ has the magnitude same as that due to the current element AB but its direction is that of vector $\overrightarrow{\mathrm{PM}}$. Thus,

$$|\overrightarrow{d\mathrm{B}}| = |\overrightarrow{d\mathrm{B}'}|$$

Both $\overrightarrow{d\mathrm{B}}$ and $\overrightarrow{d\mathrm{B}'}$ can be resolved into two mutually perpendicular components along PX and ZZ′. The components of the magnetic fields due to current elements AB and A′B′ along ZZ′ cancel each other, as they are equal in magnitude and opposite in direction. The same will hold for such other pairs of current elements over the entire circumference of the loop. Therefore, due to the various current elements, the components of magnetic field only along PX will contribute to the magnetic field due to the whole loop at point P.

If $\angle \mathrm{OPC} = \angle \mathrm{OPC}' = \theta$, then $\angle \mathrm{ZPL} = \angle \mathrm{Z'PM} = \theta$. Therefore,

effective component of magnetic field due to a current element = $d\mathrm{B}\sin\theta$ (along PX)

The magnetic field at point P due to the whole loop is obtained by integrating $d\mathrm{B}\sin\theta$ over the circumference of the loop. Therefore, the magnetic field at point P due to the whole circular loop,

$$\mathrm{B} = \oint d\mathrm{B}\sin\theta = \oint \frac{\mu_0}{4\pi} \cdot \frac{\mathrm{I}\,dl}{r^2}\sin\theta = \frac{\mu_0}{4\pi} \cdot \frac{\mathrm{I}}{r^2}\sin\theta \oint dl$$

Now, $\oint dl = 2\pi a$, circumference of the loop of radius a

$$\therefore \quad \mathrm{B} = \frac{\mu_0}{4\pi} \cdot \frac{\mathrm{I}}{r^2}\sin\theta\,(2\pi a) = \frac{\mu_0}{4\pi} \cdot \frac{2\pi \mathrm{I} a}{r^2}\sin\theta$$

From right angled triangle OPC, $\sin\theta = \frac{a}{r}$

$$\therefore \quad \mathrm{B} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi \mathrm{I} a}{r^2} \times \frac{a}{r} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi \mathrm{I} a^2}{r^3}$$

But $\quad r = (a^2 + x^2)^{1/2}$

$$\therefore \quad \mathrm{B} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi \mathrm{I} a^2}{(a^2 + x^2)^{3/2}} \qquad \text{...(1.15)}$$

If the circular loop consists of n turns, then strength of the magnetic field at point P due to the loop will be n times the magnetic field due to a loop of single turn *i.e.* n times the magnetic field given by the equation (1.15). Therefore, for a loop of n turns,

$$\mathrm{B} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n \mathrm{I} a^2}{(a^2 + x^2)^{3/2}} \qquad \text{...(1.16)}$$

Key point ✓

For a point on the axis of a circular coil carrying current, magnetic field is maximum at the centre of the coil.

The equations (1.15) and (1.16) give the magnitude of the magnetic field produced due to the flow of current through a circular loop at a point on its axis. For the current flowing in the direction as shown in Fig. 1.10, the direction of the magnetic field produced due to the loop is along PX.

Special cases. Let us consider the following two cases :

1. ***Magnetic field at the centre of the loop.*** When the point P lies at the centre of the loop, $x = 0$. Therefore, setting $x = 0$ in equation (1.15), we have

$$\mathrm{B} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi \mathrm{I}}{a} \qquad \text{...(1.17)}$$

It gives the magnetic field due to a current carrying circular loop of radius a at its centre and is the same as obtained in the form of equation (1.12).

For a circular loop of n turns, the expression will be

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} \qquad ...(1.18)$$

2. ***When the observation point lies far away from the centre of the loop.*** In case e observation point P lies at a distance very large as compared to the radius of e loop *i.e.* if $x >> a$, then in equation (1.15), a^2 can be neglected as compared to . Therefore, in such a case,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I a^2}{x^3} \qquad ...(1.19)$$

But $\pi a^2 = A$, the area of the circular loop . Therefore, equation (1.19) becomes

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2 I A}{x^3} \qquad ...(1.20)$$

The equations (1.19) and (1.20) give the magnetic field due to a current carrying rcular loop at a far away point on the axis of the loop.

Similarly, for a loop of n turns,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I a^2}{x^3} = \frac{\mu_0}{4\pi} \cdot \frac{2 n I A}{x^3} \qquad ...(1.21)$$

1.08. AMPERE'S CIRCUITAL LAW

It states that *the line integral of magnetic field ($\vec{B}$) around any closed path or circuit equal to μ_0 (absolute permeability of free space) times the total current (I) threading the osed circuit.*

Mathematically, $\oint \vec{B} \cdot \vec{dl} = \mu_0 I$ ...(1.22)

Ampere's circuital law can be proved, when a current threads a closed path any shape. However, before proving Ampere's circuital law for any arbitrary osed path, we first prove it for a special case *i.e.* for a circular path around a long irrent carrying conductor.

(*a*) To prove Ampere's circuital law for a circular path. Consider a long straight onductor XY, such that a current I flows through it from the end X to Y [Fig. 1.09]. ue to flow of current through the conductor, the magnetic field will be produced round it.

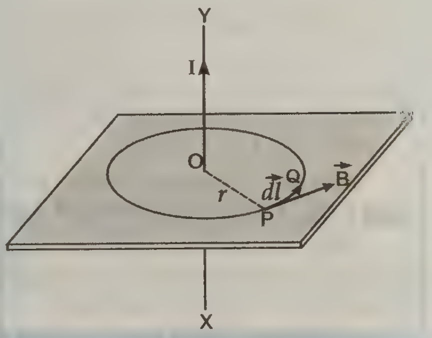

Fig. 1.09

Consider a small element of length $\overrightarrow{PQ}$ $(= \vec{dl})$ of the circular path. Let $\vec{B}$ be the rength of magnetic field at point P. According to the right hand thumb rule, the irection of magnetic field at point P is along tangent to the circular path at that point.

bviously, the vectors $\vec{B}$ and $\vec{dl}$ are along the same direction. Hence, the line integral f magnetic field over the closed circular path is given by

$$\oint \vec{B} \cdot \vec{dl} = \oint B\, dl \cos 0° = \oint B\, dl \qquad ...(1.23)$$

The magnitude of magnetic field due to the current carrying straight conductor point P is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r}$$

In fact, the magnitude of magnetic field is same for all the points on the circular ath around the conductor. Substituting for B in equation (1.23), we have

$$\oint \vec{B} \cdot \vec{dl} = \oint \frac{\mu_0}{4\pi} \cdot \frac{2I}{r}\, dl = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r} \oint dl$$

Now, $\oint dl$ = circumference of the circle of radius $r = 2\pi r$

$$\therefore \quad \oint \vec{B} \cdot \vec{dl} = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r} \cdot 2\pi r \quad \text{or} \quad \oint \vec{B} \cdot \vec{dl} = \mu_0 I$$

It proves Ampere's circuital law.

It may be noted that the magnitude of magnetic field at a point on the circular ath changes with the change in radius of the circular path but the line integral f $\vec{B}$ over any closed circular path will be independent of its radius *i.e.* equal to μ_0 mes the current threading the circle.

(b) To prove Ampere's circuital law for any arbitrary path. Consider any arbitrary closed path around a long straight conductor XY carrying current I as shown in Fig. 1.10. Divide the circular path into a large number of segments of infinitesimally small lengths $\overrightarrow{AB}\ (=\vec{dl_1})$, $\overrightarrow{BC}\ (=\vec{dl_2})$, $\overrightarrow{CD}\ (=\vec{dl_3})$, ... Suppose that these segments of small lengths subtend angles $d\theta_1, d\theta_2, d\theta_3$ ..... at the point O, through which the conductor passes. Obviously,

$$d\theta_1 + d\theta_2 + d\theta_3 ..... = 2\pi \qquad ...(1.24)$$

Suppose that all the segments AB, BC, CD, ... are small circular arcs of radii r_1, r_2, r_3, .. respectively. Then,

$$d\theta_1 = \frac{dl_1}{r_1}, d\theta_2 = \frac{dl_2}{r_2}, d\theta_3 = \frac{dl_3}{r_3}, ... \qquad ...(1.25)$$

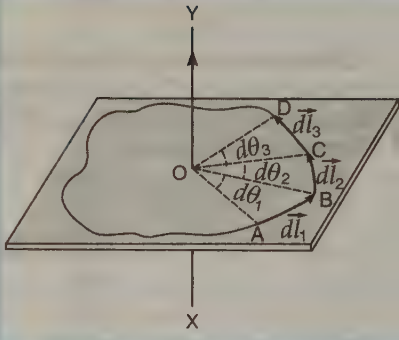

Fig. 1.10

If $\vec{B_1}, \vec{B_2}, \vec{B_3}$..... are strengths of $\vec{B}$ along $\vec{dl_1}, \vec{dl_2}, \vec{dl_3}$ ...., then the line integral of $\vec{B}$ along the arbitrary closed path can be expressed as

$$\oint \vec{B} \cdot \vec{dl} = \vec{B_1} \cdot \vec{dl_1} + \vec{B_2} \cdot \vec{dl_2} + \vec{B_3} \cdot \vec{dl_3} + ... = B_1(dl_1) + B_2(dl_2) + B_3(dl_3) + ...$$

Now, $$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r_1}; B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r_2}; B_3 = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r_3}; .....$$

$$\therefore \quad \oint \vec{B} \cdot \vec{dl} = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r_1}(dl_1) + \frac{\mu_0}{4\pi} \cdot \frac{2I}{r_2}(dl_2) + \frac{\mu_0}{4\pi} \cdot \frac{2I}{r_3}(dl_3) + ...$$

$$= \frac{\mu_0}{4\pi} \cdot 2I\left(\frac{dl_1}{r_1} + \frac{dl_2}{r_2} + \frac{dl_3}{r_3} + ...\right)$$

Using equation (1.25), we obtain

$$\oint \vec{B} \cdot \vec{dl} = \frac{\mu_0}{4\pi} \cdot 2I(d\theta_1 + d\theta_2 + d\theta_3 + ...)$$

Again, using equation (1.24), we have

$$\oint \vec{B} \cdot \vec{dl} = \frac{\mu_0}{4\pi} \cdot 2I(2\pi)$$

or $$\oint \vec{B} \cdot \vec{dl} = \mu_0 I$$

It proves Ampere's circuital law in a general case.

1.09. APPLICATIONS OF AMPERE'S CIRCUITAL LAW

We now apply Ampere's circuital law so as to obtain expressions for magnetic field due to current flowing through a long straight conductor, a long straight solenoid and a toroidal solenoid.

1. Magnetic field due to a long current carrying wire. Consider an infinitely long wire XY carrying current I as shown in Fig. 1.09. Suppose that P is the point at a distance r from the conductor, where the magnetic field due to the current carrying wire is to be determined. Draw a circle of radius r passing through point P, such that the wire XY is normal to the plane of the circle and passes through its centre. If $\vec{B}$ is the magnetic field at point P due to the current carrying wire and $\overrightarrow{PQ} = \vec{dl}$ is small element of the circle drawn around the wire, then

line integral of magnetic field along the circular path $= \oint \vec{B} . \vec{dl}$

Since the current threading the circular path is I ; according to Ampere's circuital law, we have

$$\oint \vec{B} . \vec{dl} = \mu_0 I \qquad ...(1.26)$$

Now, the angle between the vectors $\vec{B}$ and $\vec{dl}$ is 0°. Therefore,

$$\oint \vec{B} . \vec{dl} = \oint B\, dl \cos 0° = \oint B\, dl = B \oint dl$$

But $\oint dl = 2\pi r =$ circumference of all the circular path of radius r

$$\therefore \quad \oint \vec{B} . \vec{dl} = B \times 2\pi r \qquad ...(1.27)$$

From equations (1.26) and (1.27), we have

$$B \times 2\pi r = \mu_0 I$$

or
$$B = \frac{\mu_0 I}{2\pi r} = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r}$$

It gives the strength of magnetic field due to an infinitely long current carrying wire at a point at distance r from it.

2. Magnetic field due to a long straight solenoid. *A solenoid is a tightly wound helical loop from an insulated wire, such that its length is very large as compared to its diameter.*

Consider a long straight solenoid having n turns per unit length and wound on a cylindrical former. When current I is passed through it, magnetic field is produced due to the solenoid as shown in Fig. 1.11.

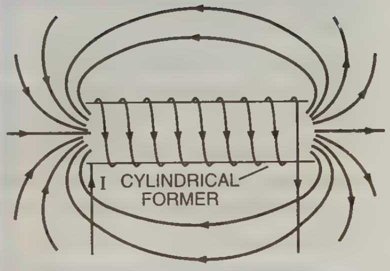

Fig. 1.11

It may be pointed out that the magnetic field produced by a straight solenoid is similar to that produced by a magnetic dipole. At points well inside the solenoid, the magnetic field is uniform and parallel to the length of the solenoid. Let $\vec{B}$ be the strength of the magnetic field at a point well inside the solenoid.

In order to determine $\vec{B}$, consider a rectangular closed path ABCD as shown in Fig. 1.12. Let the length of the rectangle be AB = L. Obviously, the number of turns of the solenoid enclosed by the rectangle is equal to n L. Since the current threads the rectangle nL times, according to Ampere's circuital law, line integral of magnetic field $\vec{B}$ along the path ABCD is equal to μ_0 (n L I), *i.e.*

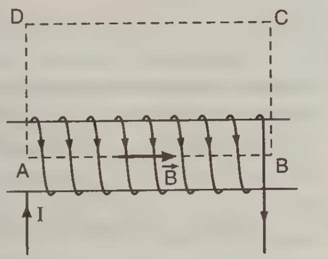

Fig. 1.12

$$\oint_{ABCD} \vec{B} \cdot \vec{dl} = \mu_0 (n L I) \qquad \text{...(1.28)}$$

Now,
$$\oint_{ABCD} \vec{B} \cdot \vec{dl} = \int_A^B \vec{B} \cdot \vec{dl} + \int_B^C \vec{B} \cdot \vec{dl} + \int_C^D \vec{B} \cdot \vec{dl} + \int_D^A \vec{B} \cdot \vec{dl} \qquad \text{...(1.29)}$$

Since direction of $\vec{B}$ is perpendicular to BC and AD,

$$\int_B^C \vec{B} \cdot \vec{dl} = \int_D^A \vec{B} \cdot \vec{dl} = 0$$

For a solenoid, whose length is much larger than its diameter, the magnetic field at points outside the solenoid is practically zero. Therefore,

$$\int_C^D \vec{B} \cdot \vec{dl} = 0$$

Using the above results, equation (1.29) becomes

$$\oint_{ABCD} \vec{B} \cdot \vec{dl} = \int_A^B \vec{B} \cdot \vec{dl} + 0 + 0 + 0 = \int_A^B \vec{B} \cdot \vec{dl}$$

As along the path AB, $\vec{B}$ and $\vec{dl}$ are along the same direction, the angle between $\vec{B}$ and $\vec{dl}$ is zero. Therefore,

$$\oint_{ABCD} \vec{B} \cdot \vec{dl} = \int_A^B B\, dl \cos 0° = B \int_A^B dl$$

Now, $\int_A^B dl$ = length of the side AB of the rectangle ABCD = L

$$\therefore \qquad \oint_{ABCD} \vec{B} \cdot \vec{dl} = B L \qquad \text{...(1.30)}$$

From equations (1.28) and (1.30), we have

$$B L = \mu_0 (n L I)$$

or $$B = \mu_0 n I \qquad ...(1.31)$$

It may be pointed out that in case of a straight long solenoid, magnetic field is given by the above formula only at a point well inside the solenoid. At points near its end, the magnetic field is given by

$$B_{end} = \frac{1}{2} \mu_0 \, n I \qquad ...(1.32)$$

Note. If the solenoid is wound on a core of a material having relative permeability μ_r, then

$$B = \mu_0 \mu_r n I \qquad ...(1.33)$$

Since $\mu_0 \mu_r = \mu$, the absolute permeability of the material of the core,

$$\therefore \quad B = \mu n I \qquad ...(1.34)$$

3. Magnetic field due to a toroidal solenoid. Consider a toroidal solenoid consisting of an anchor ring of radius r, over which a large number of turns of a metallic wire are wound. Let n be the number of turns per unit length and the point O be its centre [Fig. 1.13].

The jargon

A toroidal solenoid is an anchor ri
(torus), around which a large number
turns of a metallic wire are wound.

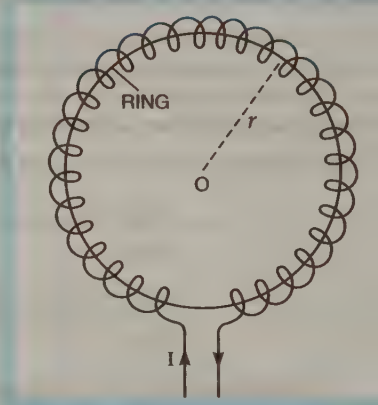

Fig. 1.13

Suppose that the current I is passed through the solenoid. The magnetic field produced will be the same at all points on the circumference of the ring of the solenoid and at any point, the direction of the magnetic field is along tangent to the ring.

According to Ampere's circuital law,

$$\oint \vec{B} \cdot \vec{dl} = \mu_0 \times \text{(the current threading the ring)} \qquad ...(1.35)$$

The current threading the ring is not simply equal to I. In fact, the current threads the ring as many times as there are turns in the solenoid wound on the ring of radius r. Since number of turns in the solenoid of radius r is equal to $2\pi r n$,

the total current threading the ring of radius r

$$= I\,(2 \pi r n) \qquad ...(1.36)$$

Further, $\vec{B}$ and $\vec{dl}$ are along same direction.

$$\therefore \quad \oint \vec{B} \cdot \vec{dl} = \oint B\, dl = B \oint dl = B\,(2 \pi r) \qquad ...(1.37)$$

Using equations (1.36) and (1.37), equation (1.35) becomes

$$B\,(2 \pi r) = \mu_0 \times I\,(2 \pi r n)$$

or $$B = \mu_0 n I \qquad ...(1.38)$$

It may be noted that magnetic field due to a toroidal solenoid depends upon its number of turns per unit length and the magnitude of the current passing through it. It does not depend upon the radius of the ring, over which the solenoid is wound.

SOLVED NUMERICAL PROBLEMS

Type A. On Magnetic field due to a straight conductor

Problem 1.01. A horizontal overhead power line carries a current of 90 A in the east to west direction. What is the magnitude and direction of magnetic field due to the current at a point 1·5 m below the line ? *(Text Problem)*

Sol. Here, $I = 90$ A ; $a = 1{\cdot}5$ m

Now, $$B = \frac{\mu_0}{4\pi} \cdot \frac{2I}{a} = 10^{-7} \times \frac{2 \times 90}{1{\cdot}5} = \mathbf{1{\cdot}2 \times 10^{-5}\ T}$$

Right hand thumb rule tells that for a current in east to west direction, the direction of magnetic field at a point below the line will be **towards south.**

Problem 1.02. A straight wire carries a current of 3 A. Calculate the magnitude of the magnetic field at a point 15 cm away from the wire. Draw a diagram to show the direction of the magnetic field. *(C.B.S.E. 1996)*

Sol. Here, $I = 3$ A ; $a = 15$ cm $= 0{\cdot}15$ m

Now, $$B = \frac{\mu_0}{4\pi} \cdot \frac{2I}{a} = \frac{10^{-7} \times 2 \times 3}{0{\cdot}15} = \mathbf{4 \times 10^{-6}\ T}$$

The direction of magnetic field will be perpendicula
the plane of paper and in inward direction as shown in F
1.14.

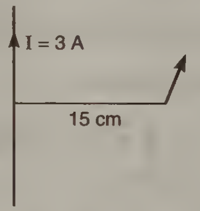

Fig. 1.14

Problem 1.03. Fig. 1.15 shows a right angled isosce triangle PQR having its base equal to a. A current c ampere is passing downwards along a thin straight w cutting the plane of the paper normally as shown at Likewise a similar wire carries an equal current passi normally upwards at R. Find the magnitude and directi

the magnetic induction B at P. Assume the wires to be initely long. (*I.C.S.E. 1997*)

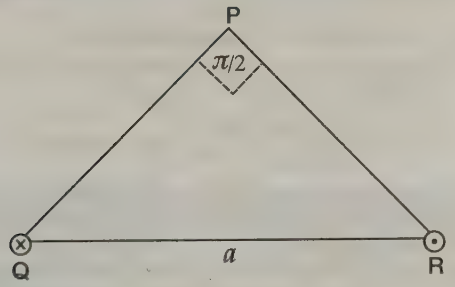

Fig. 1.15

Ans. It follows that ∠ PQR = ∠ PRQ = 45°.

Therefore, $PQ = PR = QR \sin 45° = a \times \frac{1}{\sqrt{2}} = \frac{a}{\sqrt{2}}$

Magnetic induction at point P due to current through nductor at point Q,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2I}{PQ} = \frac{\mu_0}{4\pi} \cdot \frac{2\sqrt{2}\,I}{a} \qquad \text{(along PR)}$$

Also, magnetic induction at point P due to current rough conductor at point R,

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2I}{PR} = \frac{\mu_0}{4\pi} \cdot \frac{2\sqrt{2}\,I}{a} \qquad \text{(along PQ)}$$

The resultant magnetic induction at point P is given by

$$B = \sqrt{B_1^2 + B_2^2 + 2\,B_1 B_2 \cos \pi/2} = \sqrt{B_1^2 + B_2^2}$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \sqrt{(2\sqrt{2})^2 + (2\sqrt{2})^2} = \frac{\mu_0}{4\pi} \cdot \frac{4I}{a} = \frac{\mu_0 I}{\pi a}$$

The direction of the resultant magnetic induction will be ong bisector of ∠ QPR and towards the line joining the ints Q and R.

Problem 1.04. Calculate the magnetic field induction the centre of a coil bent in the form of a square of side cm carrying current of 10 A. (*P.S.S.C.E. 2001*)

Sol. Let B′ be the magnetic field induction at the centre of the square due to current passing through one side of e square. Since the magnetic field induction at point O due all the four sides is same and perpendicular to the plane the paper in outward direction, the total magnetic field duction due to the square,

$$B = 4\,B'$$

Now, $B' = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} (\sin \phi_1 + \sin \phi_2)$,

here a is the perpendicular distance of point O from any side the square [Fig. 1.16].

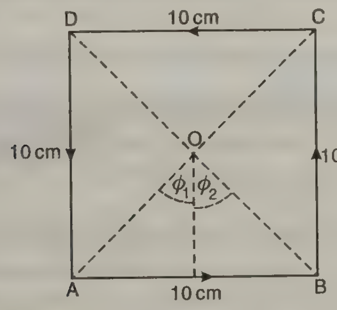

Fig. 1.16

Here, $I = 10\text{ A}, a = \frac{AD}{2} = \frac{10}{2} = 5\text{ cm} = 0{\cdot}05\text{ m}$

and $\phi_1 = \phi_2 = 45°$

$$\therefore \quad B' = 10^{-7} \times \frac{10}{0{\cdot}05} (\sin 45° + \sin 45°) = 2{\cdot}83 \times 10^{-5}\text{ T}$$

Hence, magnetic field induction due to the whole square,

$$B = 4 \times 2{\cdot}83 \times 10^{-5} = 1{\cdot}13 \times 10^{-4}\text{ T}$$

(perpendicular to paper in outward direction)

Type B. On Magnetic field due to a circular coil at its centre

Problem. 1.05. The plane of a circular coil is horizontal. It has 10 turns, each of 8 cm radius. A current of 2 A flows through it, which appears clockwise from a point vertically above it. Find the magnitude and direction of the magnetic field at the centre of the coil due to the current.

Sol. Here, $n = 10\,;\ a = 8\text{ cm} = 0{\cdot}08\text{ m}\,;\ I = 2\text{ A}$

We know, $\frac{\mu_0}{4\pi} = 10^{-7}\text{ Wb A}^{-1}\text{ m}^{-1}$

Now, magnetic field at the centre of the coil,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} = \frac{10^{-7} \times 2\pi \times 10 \times 2}{0{\cdot}08}$$

$$= 1{\cdot}57 \times 10^{-4}\text{ T}$$

Since the current is clockwise as seen from a point vertically above the coil, the direction of the field is **vertically downwards.**

Problem 1.06. The radius of the first electron orbit of a hydrogen atom is 0·5 Å. The electron moves in this orbit with a uniform speed of 2·2 ×10^{-6} m s^{-1}. What is the magnetic field produced at the centre of the nucleus due to the motion of this electron ? Use $\frac{\mu_0}{4\pi} = 10^{-7}$ N A^{-2} and electronic charge = 1·6 × 10^{-19} C. (*I.S.C.E. 1998*)

Sol. Here, uniform speed of electron,

$$v = 2{\cdot}2 \times 10^{-6}\text{ m s}^{-1}\,;$$

Radius of the electron orbit in hydrogen atom,

$$a = 0{\cdot}5\text{ Å} = 0{\cdot}5 \times 10^{-10}\text{ m}\,;$$

and charge on electron, $e = 1{\cdot}6 \times 10^{-19}$ C

and $\frac{\mu_0}{4\pi} = 10^{-7}\text{ N A}^{-2}$

Time taken by the electron to complete one revolution in the orbit of hydrogen atom,

$$T = \frac{\text{circumference of orbit}}{\text{speed of electron}} = \frac{2\pi a}{v}$$

Therefore, at any point on the electron orbit, a charge equal to e (charge on the electron) crosses after every T seconds. Therefore, revolution of the electron in the orbit is equivalent to the current I, given by

$$I = \frac{q}{t} = \frac{e}{T} = \frac{e\,v}{2\pi a}$$

$$= \frac{1{\cdot}6 \times 10^{-19} \times 2{\cdot}2 \times 10^{6}}{2\pi \times 0{\cdot}5 \times 10^{-10}} = 1{\cdot}12 \times 10^{-3}\text{ A}$$

If B is the magnetic field produced at the centre of the nucleus due to the motion of the electron, then

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{a} = \frac{10^{-7} \times 2\pi \times 1{\cdot}12 \times 10^{-3}}{0{\cdot}5 \times 10^{-10}}$$

$$= 14{\cdot}07\text{ T}$$

Problem 1.07. A straight wire carrying a current of 12 A is bent into a semicircular arc of radius 2·0 cm as shown in Fig. 1.17.

(i) What is the direction and magnitude of magnetic field at the centre of the arc ? (*P.S.S.C.E. 1991*)

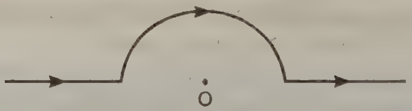

Fig. 1.17

(ii) Would your answer change, if the wire were bent into a semicircular arc of the same radius but in the opposite way as shown in Fig. 1.18 ? (*Text Problem*)

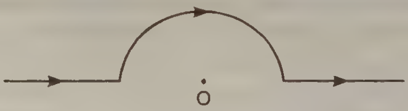

Fig. 1.18

Sol. (*i*) ***For Fig. 1.17*** **:** The magnetic field at the centre of a current carrying circular coil is given by

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2\pi I}{a}$$

For magnetic field at the centre O of the semicircular conductor, the above equation will modify to

$$B = \frac{1}{2}\times\frac{\mu_0}{4\pi}\cdot\frac{2\pi I}{a} = \frac{\mu_0}{4\pi}\cdot\frac{\pi I}{a}$$

Here, $I = 12$ A ; $a = 2{\cdot}0$ cm $= 2{\cdot}0\times10^{-2}$ m

$$\therefore \quad B = 10^{-7}\times\frac{\pi\times12}{2{\cdot}0\times10^{-2}} = \mathbf{1{\cdot}885\times10^{-4}\ T}$$

The direction of the field will be **normal to plane of the paper** and in **inward direction.**

(*ii*) ***For Fig. 1.18*** **:** The field will be of the same magnitude *i.e.* **$1{\cdot}885\times10^{-4}$ T**, but its direction will be **normal to the plane of paper** and in **outward direction.**

Problem 1.08. The wire shown in the Fig. 1.19. carries a current of 10 A. Determine the magnitude of magnetic field induction at the centre O. Given that radius of the bent coil is 3 cm. (*P.S.S.C.E. 2001*)

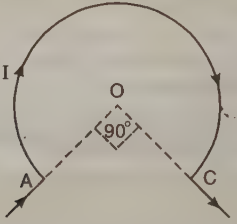

Fig. 1.19

Sol. The magnetic field induction at the centre of a current carrying circular wire of radius *a* is given by

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2\pi I}{a}$$

A circular wire subtends an angle of 2 π radians at its centre. Suppose that the given circular part ABC of the wire subtends an angle θ at its centre. Then, magnetic field at point O due to circular part ABC is given by

$$B' = B\times\frac{\theta}{2\pi} = \frac{\mu_0}{4\pi}\cdot\frac{2\pi I}{a}\times\frac{\theta}{2\pi}$$

or $$B' = \frac{\mu_0}{4\pi}\cdot\frac{I}{a}\theta$$

Here, $I = 10$ A ; $a = 3$ cm $= 0{\cdot}03$ m

and $\theta = 360° - 90° = 270° = \dfrac{3\pi}{2}$ rad

$$\therefore \quad B' = \frac{10^{-7}\times10\times3\pi}{0{\cdot}03\times2} = \mathbf{1{\cdot}57\times10^{-4}\ T}$$

Note. The two end straight parts of the coil do no produce any magnetic field at point O. It is because, point lies on these straight parts.

Problem 1.09. As shown in Fig. 1.20, a cell is connecte across points X and Y of a uniform circular conductor. Prov that the magnetic field at its centre will be zero. (*P.S.S.C.E. 1999*

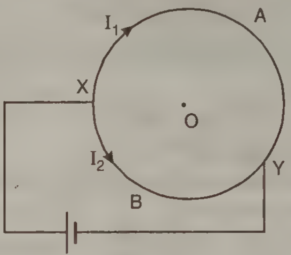

Fig. 1.20

Sol. Let I_1 and I_2 be the currents flowing through th parts XAY and XBY of the circular conductor. Suppose tha the parts XAY and XBY subtend angles θ_1 and θ_2 at the centr O. If *a* is radius of the circular conductor, then magnetic fiel due to part XAY at point O,

$$B_1 = \frac{\mu_0}{4\pi}\cdot\frac{I_1}{a}\theta_1 \quad \text{...(}$$

(perpendicular to paper and in inward directio

Also, magnetic field due to part XBY at point O,

$$B_2 = \frac{\mu_0}{4\pi}\cdot\frac{I_2}{a}\theta_2 \quad \text{...(}i$$

(perpendicular to paper and in outward directio

If *r* is resistance per unit length of the circular conducto then resistances of the parts XAY and XBY are given by

$$R_1 = (a\,\theta_1)\,r \quad \text{and} \quad R_2 = (a\,\theta_2)\,r$$

Since the two parts are connected between the same tw points, potential difference across their ends will be same *i.*

$$I_1 R_1 = I_2 R_2 \quad \text{or} \quad I_1\,(a\,\theta_1)\,r = I_2\,(a\,\theta_2)\,r$$

or $$I_1\,\theta_1 = I_2\,\theta_2$$

From equations (*i*) and (*ii*), it follows that magnetic fiel B_1 and B_2 due to the two parts of the circular conductor a equal and opposite. Hence, the magnetic field at the centr of the circular conductor is **zero.**

Type C. On Magnetic field due to a circular coil at point on axis

Problem 1.10. Calculate the magnetic field due to circular coil of 500 turns and of diameter 0·1 m, carrying current of 7 A (*a*) at a point on the axis of the coil dista 0·12 m (*b*) at the centre of the coil.

Sol. (*a*) Here $n = 500$; $I = 7$ A ; $a = \dfrac{0{\cdot}1}{2} = 0{\cdot}05$ m ;

$x = 0{\cdot}12$ m

Now, magnetic field at a point on axis of the coil,

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2\pi n I a^2}{(a^2+x^2)^{3/2}} = \frac{10^{-7}\times2\pi\times500\times7\times(0{\cdot}05)^2}{\{(0{\cdot}05)^2+(0{\cdot}12)^2\}^{3/2}}$$

$$= \frac{2\pi\times500\times7\times25\times10^{-4}\times10^{-7}}{(0\cdot0169)^{3/2}}$$

$= 2\cdot5\times10^{-3}$ **tesla**

(*b*) Now, magnetic field at the centre of the coil,

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2\pi n I}{a} = \frac{10^{-7}\times2\pi\times500\times7}{0\cdot05}$$

$= 4\cdot4\times10^{-2}$ **tesla**

Problem 1.11. An electric current is flowing in a cular wire of radius *a*. At what distance from the centre the axis of the circular wire will the magnetic field be th of its value at the centre ?

Sol. Let B be the magnetic field at the centre of the cular wire, when a current I passes through it. Then,

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2\pi I}{a} \qquad ...(i)$$

Let x be the distance on the axis of the circular wire from centre, where the magnetic field is $\frac{B}{8}$. Then,

$$\frac{B}{8} = \frac{\mu_0}{4\pi}\cdot\frac{2\pi I a^2}{(a^2+x^2)^{3/2}} \qquad ...(ii)$$

From equations (*i*) and (*ii*), we have

$$\frac{\mu_0}{4\pi}\cdot\frac{2\pi I a^2}{(a^2+x^2)^{3/2}} = \frac{1}{8}\times\frac{\mu_0}{4\pi}\cdot\frac{2\pi I}{a}$$

or $$\frac{a^2}{(a^2+x^2)^{3/2}} = \frac{1}{8a}$$

or $(a^2+x^2)^{3/2} = 8a^3$ or $a^2+x^2 = 4a^2$

or $x = \sqrt{3}\,a$

pe D. On Ampere's Circuital law

Problem 1.12. A long straight solid conductor of radius m carries a current of 2 A, which is uniformly distributed er its circular cross-section. Find the magnetic field duction at a distance of 3 cm from the axis of the nductor.

Sol. To find the magnetic field at a point P at distance = 3 cm) due to current carrying conductor, imagine a cular path of radius *r* around the conductor, such that int P lies on it. If R is the radius of the solid conductor, en current enclosed by the circular path,

$$I' = \frac{I}{\pi R^2}\times\pi r^2 = \frac{I r^2}{R^2}$$

. Let B be magnetic field at point P due to the current carr- ng conductor. The magnetic field B acts tangential to the cular path and its magnitude is same at every point on it. Therefore, according to Ampere's circuital law,

$$\oint \vec{B}\cdot\vec{dl} = \mu_0 I'$$

or $$B\times2\pi r = \mu_0\frac{I r^2}{R^2}$$

or $$B = \frac{\mu_0}{2\pi}\cdot\frac{I r}{R^2} = \frac{\mu_0}{4\pi}\cdot\frac{2 I r}{R^2}$$

Here, $I = 2$ A, $r = 3$ cm $= 0\cdot03$ m and R = 5 cm = 0·05 m

$$\therefore \quad B = \frac{10^{-7}\times2\times2\times0\cdot03}{(0\cdot05)^2} = 4\cdot8\times10^{-6}\ \mathrm{T}$$

Note. As the point lies inside the conductor, the magnetic field produced will be μ_r times the value obtained above, where μ_r is permeability of the material of the conductor.

Type E. On Magnetic field due to a Solenoid

Problem 1.13. A 0·5 m long solenoid has 500 turns and has a flux density of $2\cdot52\times10^{-3}$ T at its centre. Find the current in the solenoid. Given, $\mu_0 = 4\pi\times10^{-7}$ H m^{-1}.
(*I.S.C.E. 1995*)

Ans. Here, $B = 2\cdot52\times10^{-3}$ T ; $\mu_0 = 4\pi\times10^{-7}$ H m^{-1}

Length of solenoid, $l = 0\cdot5$ m ; total number of turns in the solenoid, N = 500

Therefore, number of turns per unit length of the solenoid,

$$n = \frac{N}{l} = \frac{500}{0\cdot5} = 1000\ \mathrm{m^{-1}}$$

If I is the current through the solenoid, then

$$B = \mu_0 n I$$

or $$I = \frac{B}{\mu_0 n} = \frac{2\cdot52\times10^{-3}}{4\pi\times10^{-7}\times1000} = 2\cdot0\ \mathrm{A}$$

Problem 1.14. A solenoid is 2 · 0 m long and 3 · 0 cm in diameter. It has 5 layers of winding of 1000 turns each and carries a current of 5 · 0 A. What is the magnetic field at its centre ? Use the standard value of μ_0. (*P.S.S.C.E. 1997 S*)

Sol . Here, current in the solenoid, I = 5 · 0 A ;
length of the solenoid, $l = 2\cdot0$ m
number of turns in each layer of winding = 1000 ;
number of layers = 5

Therefore, total number of turns in the solenoid,

N = 1000 × 5 = 5000

and the number of turns per unit length of the solenoid,

$$n = \frac{N}{l} = \frac{5000}{2\cdot0} = 2500\ \mathrm{m^{-1}}$$

Now, $B = \mu_0 n I$

Since $\mu_0 = 4\pi\times10^{-7}$ N A^{-2}, we have

$B = 4\pi\times10^{-7}\times2500\times5\cdot0 = 1\cdot57\times10^{-2}$ **T**

TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 1.15. Two concentric circular coils X and Y of radii 16 cm and 10 cm respectively lie in the same rtical plane containing the north-south direction. Coil X s 20 turns and carries a current of 16 A ; coil Y has 25 rns and carries a current of 18 A. The sense of the rrent in X is anticlockwise and in Y clockwise for an server looking at the coils facing west. Give the magnitude and direction of the net magnetic field due to the coils at their centres. (*Text Problem*)

Sol. *For coil X* : $a = 16$ cm $= 16\times10^{-2}$ m ; $n = 20$; I = 16 A

Magnetic field at the centre of the coil X,

$$B_x = \frac{\mu_0}{4\pi}\cdot\frac{2\pi n I}{a} = 10^{-7}\times\frac{2\pi\times20\times16}{16\times10^{-2}}$$

$= 4\pi\times10^{-4}$ T (towards east)

For coil Y : $a = 10 \text{ cm} = 10 \times 10^{-2}$ m ; $n = 25$; I = 18 A
Magnetic field at the centre of the coil Y,

$$B_y = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} = 10^{-7} \times \frac{2\pi \times 25 \times 18}{10 \times 10^{-2}}$$

$$= 9\pi \times 10^{-4} \text{ T (towards west)}$$

Therefore, net magnetic field at the centre of the two coils,

$$B = B_y - B_x = 9\pi \times 10^{-4} - 4\pi \times 10^{-4} = 5\pi \times 10^{-4} \text{ T}$$

(towards west)

Problem 1.16. Two infinitely long straight current carrying conductors are held at right angles to each other so that their common end lies at the origin [Fig. 1.21]. If both the conductors carry the same current I as shown in the figure, find the value of magnetic field at the point P (*a*, *b*).

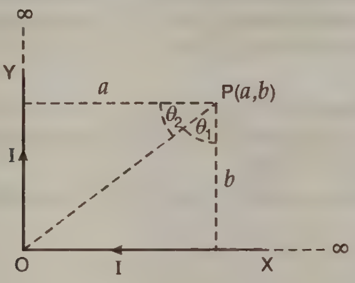

Fig. 1.21

Sol. The magnetic field due to a straight conductor is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} (\sin \phi_1 + \sin \phi_2) \quad ...(i)$$

Let B_1 and B_2 be the magnetic fields at point P due to the conductors lying along X-axis and Y-axis respectively.

For the conductor lying along X-axis,

$$\phi_1 = \theta_1 ; \phi_2 = \pi/2 \text{ and } a = b$$

$$\therefore \quad B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I}{b} (\sin \theta_1 + \sin \pi/2)$$

$$\text{or} \quad B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I}{b} \left(\frac{a}{\sqrt{a^2 + b^2}} + 1 \right)$$

For the conductor lying along Y-axis,

$$\phi_1 = \theta_2 ; \phi_2 = \pi/2 \text{ and } a = a$$

$$\therefore \quad B_2 = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} (\sin \theta_2 + \sin \pi/2)$$

$$\text{or} \quad B_2 = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \left(\frac{b}{\sqrt{a^2 + b^2}} + 1 \right)$$

According to the right hand thumb rule, both B_1 and B_2 act perpendicular to the plane of paper and in inward direction. Therefore, resultant magnetic field at point P,

$$B = B_1 + B_2$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I}{b} \left(\frac{a}{\sqrt{a^2 + b^2}} + 1 \right) + \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \left(\frac{b}{\sqrt{a^2 + b^2}} + 1 \right)$$

$$= \frac{\mu_0 I}{4\pi} \cdot I \left[\frac{1}{\sqrt{a^2 + b^2}} \left(\frac{a}{b} + \frac{b}{a} \right) + \left(\frac{1}{b} + \frac{1}{a} \right) \right]$$

$$= \frac{\mu_0}{4\pi} I \left[\frac{1}{\sqrt{a^2 + b^2}} \left(\frac{a^2 + b^2}{a b} \right) + \frac{a + b}{a b} \right]$$

$$\text{or} \quad B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a b} \left[\sqrt{a^2 + b^2} + a + b \right]$$

Problem 1.17. An infinitely long conductor is bent ir the shape as shown in Fig. 1.22. The part semicircul in shape lies in YZ-plane, while of the two straight par one is along X-axis and the other parallel to Y-axis a distance *r* from it. If the conductor carries a current I shown in the figure, find the magnetic field at the cent C of the semi-circular loop.

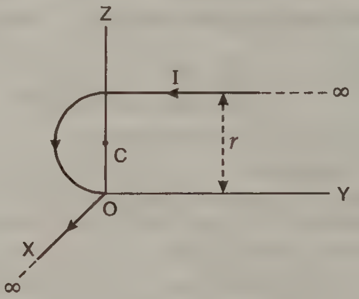

Fig. 1.22

Sol. Let $\vec{B}_1$, $\vec{B}_2$ and $\vec{B}_3$ be respectively the magne fields at point C due to straight part lying along X-axis, sen circular part and straight part lying parallel to Y-axis.

Due to a current carrying straight conductor,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} (\sin \phi_1 + \sin \phi_2)$$

For straight part lying along X-axis

$$\phi_1 = \pi/2, \quad \phi_2 = 0 \text{ and } \quad a = r/2$$

$$\therefore \quad B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r/2} (\sin \pi/2 + \sin 0)$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{2I}{r} \quad \text{(along negative Y-axis)}$$

$$\therefore \quad \vec{B}_1 = -\frac{\mu_0}{4\pi} \cdot \frac{2I}{r} \hat{j}$$

The semicircular part subtends angle π at its centre. Al radius of semi-circular part is $r/2$. Therefore, for semi-circu part lying in YZ-plane.

$$\therefore \quad B_2 = \frac{\mu_0}{4\pi} \cdot \frac{I}{(r/2)} \pi$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r} \quad \text{(along positive X-axis)}$$

$$\text{or} \quad \vec{B}_2 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r} \hat{i}$$

For straight part lying parallel to Y-axis,

$$\phi_1 = \pi/2, \quad \phi_2 = 0 \text{ and } \quad a = r/2$$

$$\therefore \quad B_3 = \frac{\mu_0}{4\pi}\cdot\frac{I}{r/2}(\sin \pi/2 + \sin 0)$$

$$= \frac{\mu_0}{4\pi}\cdot\frac{2I}{r} \text{ (along positive X-axis)}$$

or $$\vec{B}_3 = \frac{\mu_0}{4\pi}\cdot\frac{2I}{r}\hat{i}$$

Therefore, total magnetic field at point C,

$$\vec{B} = \vec{B}_1 + \vec{B}_2 + \vec{B}_3$$

$$= -\frac{\mu_0}{4\pi}\cdot\frac{2I}{r}\hat{j} + \frac{\mu_0}{4\pi}\cdot\frac{2\pi I}{r}\hat{i} + \frac{\mu_0}{4\pi}\cdot\frac{2I}{r}\hat{i}$$

$$= \frac{\mu_0}{4\pi}\cdot\frac{2I}{r}\left[(\pi+1)\hat{i} - \hat{j}\right]$$

Problem 1.18. A toroid has a core (non-ferromagnetic) of inner radius 25 cm and outer radius 26 cm around vhich 3500 turns of a wire are wound. If the current in the vire is 11 A, what is the magnetic field (*a*) outside the toroid b) inside the core of the toroid (*c*) in the empty space urrounded by the toroid ? (*Text Problem*)

Sol. Here, I = 11 A ; total number of turns = 3500

Mean radius of toroid,

$$r = \frac{25+26}{2} = 25\cdot5 \text{ cm} = 25\cdot5\times10^{-2} \text{ m}$$

Total length (circumference) of the toroid

$$= 2\pi r = 2\pi\times 25\cdot5\times10^{-2} = 51\cdot0\times10^{-2}\,\pi \text{ m}$$

Therefore, number of turns per unit length,

$$n = \frac{3500}{51\cdot0\times10^{-2}\,\pi}$$

(*a*) The field is non-zero only inside the core surrounded by the windings of the toroid. Therefore, the field outside the toroid is **zero.**

(*b*) The field inside the core of the toroid,

$$B = \mu_0 n I = 4\pi\times10^{-7}\times\frac{3500}{51\cdot0\times10^{-2}\,\pi}\times 11$$

$$= \mathbf{3\cdot02\times10^{-2}\ T}$$

(*c*) For the reason given in (*a*), the field in the empty space surrounded by the toroid is also zero.

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 1.01. Is the source of magnetic field analogue to the ource of electric field ? (*H.S.S.C.E. 1992*)

Ans. No. It is because, the source of magnetic field is not magnetic charge. In case of electric field, the source of lectric field is electric charge.

Q. 1.02. State Biot Savart's law. (*I.S.C.E. 1994*)

Ans. It states that magnetic field due to small conductor f length *dl*, carrying a current I at a point at distance *r*, is given y

$$dB = \frac{\mu_0}{4\pi}\cdot\frac{I\,dl\sin\theta}{r^2},$$

vhere θ is the angle between the direction of flow of urrent and the line joining the small conductor to the bservation point.

Q. 1.03. A conductor carrying current is placed somevhere. What is the magnitude and direction of the force due o a small part of the conductor at a point near it ? (*P.S.S.C.E. 1996*)

Or

Write Biot Savart expression for the magnetic field due o a current element in vector form. (*C.B.S.E. 1991 S, 1991*)

Ans. $$d\vec{B} = \frac{\mu_0}{4\pi}\cdot\frac{I\,d\vec{l}\times\vec{r}}{r^3},$$

vhere the letters have their usual meanings.

Q. 1.04. What is the SI unit of permeability ? (*I.S.C.E. 1996*)

Ans. The SI unit of permeability is **weber ampere^{-1} netre^{-1}(Wb A^{-1}m^{-1})** or **tesla ampere^{-1} metre (T A^{-1} m).**

Q. 1.05. What is the value of constant $\frac{\mu_0}{4\pi}$?

Sol. $\frac{\mu_0}{4\pi} = 10^{-7}$ T A^{-1} m

Q. 1.06. Write the dimensional formula of μ_0.

Sol. The dimensional formula of μ_0 is [M L T^{-2} A^{-2}].

Q. 1.07. Write an expression for the magnetic field produced by an infinitely long straight wire carrying a current I, at a short perpendicular distance *a* from itself. (*I.S.C.E. 1998*)

Ans. It is given by

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2I}{a}$$

Q. 1.08. What kind of magnetic field is produced due to a current carrying straight conductor ?

Sol. Magnetic field lines are concentric circles lying in a plane perpendicular to the straight conductor. The centres of the circular magnetic lines of force lie on the conductor.

Q. 1.09. Show the magnetic lines of force around a straight conductor carrying current. (*P.S.S.C.E. 1997 S*)

Ans. Refer to Fig. 1.04.

Q. 1.10. State the rule that is used to find the direction of field acting at a point near a current carrying straight conductor. (*P.S.S.C.E. 1998*)

Ans. Right hand thumb rule can be used to find the direction of magnetic field at a point near a current carrying conductor.

For statement, refer to section 1.04.

Q. 1.11. Does a current carrying circular coil produce uniform magnetic field ?

Sol. No, magnetic field produced due to a current carrying circular coil is not uniform. However, it may be considered as uniform at the centre of the circular coil.

Q. 1.12. What is the effect of increasing the number of turns on magnetic field produced due to a circular coil ?

Ans. The magnetic field produced by a coil of *n* turns is *n* times the magnetic field produced by a coil of single turn.

Q. 1.13. How will the magnetic field intensity at the centre of a circular coil carrying current change, if the current through the coil is doubled and the radius of the coil is halved ? (*C.B.S.E. 2001*)

Sol. The magnetic field at the centre of a circular coil is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a}$$

$$\therefore \quad \frac{B'}{B} = \frac{I'}{a'} \times \frac{a}{I} \qquad \text{(number of turns unchanged)}$$

If $I' = 2I$ and $a' = a/2$, then

$$\frac{B'}{B} = \frac{2I}{a/2} \times \frac{a}{I} = 4 \quad \text{or} \quad B' = 4B$$

Q. 1.14. Looking at a circular coil, the current is found to be flowing in anticlockwise direction. Predict the direction of magnetic field produced at a point on the axis of the coil on the same side as the observer.

Ans. The direction of magnetic field is perpendicular to the plane of the coil and directed towards the observer.

Q. 1.15. Write down an expression for the flux density B inside a long straight solenoid, explaining the symbol used. (*I.S.C.E. 1995*

Or

How much is the flux density B at the centre of a lon solenoid ? (*I.S.C.E. 1997*

Ans. Magnetic field due to a long straight solenoid at point well inside is given by

$$B = \mu_0 n I$$

Here, μ_0 is the permeability of free space, n is th number of turns per unit length and I is the current flowin through it.

Q. 1.16. What kind of magnetic field is produced du to straight solenoid ?

Ans. The magnetic field produced by a straight solenoi is similar to that produced by a bar magnet.

Q. 1.17. What is a toroid ?

Ans. An anchor ring, around which a large number o turns of a metallic wire are wound, is called a toroid.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 1.01. What is the basic difference between magnetic and electric field ? (*P.S.S.C.E. 2002*)

Or

In what way is an electric field different from a magnetic field ?

Ans. A charged particle always experiences force due to an electric field. It does not matter ; whether the charged particle is at rest or is in motion. However, due to magnetic field, force on a charged particle acts only, when it moves inside the magnetic field and its motion is not along the direction of the magnetic field. Further, when electric field acts, the kinetic energy of the charged particle is affected. However, there is no effect on the kinetic energy of a charged particle due to its motion inside the magnetic field.

Q. 1.02. In what respect does a wire carrying a current differ from a wire, which carries no current ? (*P.S.S.C.E. 1996*)

Ans. A current carrying wire produces magnetic field. It is because, when current flows through a wire, electrons move inside it along a definite direction. On the other hand, in a wire which carries no current, electrons are in motion in random direction. Such a wire does not produce any magnetic field.

Q. 1.03. Explain the rule, with illustration, related to the direction of current through a conductor and magnetic field. (*P.S.S.C.E. 1997*)

Sol. When current passes through a straight conductor, magnetic field is in the form of concentric circles, whose centres lie on the conductor. The sense of the circular field lines can be known by using ***right hand thumb rule.***

For statement of right hand thumb rule, refer to section 1.04.

Q. 1.04. A metallic wire is bent into a square of each side *a*. If a current I is passed through the wire, what is the magnetic field at the centre of the square ?

Sol. Refer to Fig. 1.17. Then, magnetic field at the centre of the square is given by

$$B = 4 \times \frac{\mu_0}{4\pi} \cdot \frac{I}{a/2} (\sin 45° + \sin 45°)$$

$$= 4 \times \frac{\mu_0}{4\pi} \cdot \frac{2I}{a}\left(\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}\right) = \frac{\mu_0}{4\pi} \cdot \frac{8\sqrt{2}\, I}{a}$$

Q. 1.05. A long wire is first bent into a circular coil o one turn and then into a circular coil of smaller radiu having *n* turns. If the same current passes in both the cases find the ratio of the magnetic fields produced at the centre in the two cases.

Sol. Let *r* be the radius of the coil formed, when the give wire is bent into a smaller circular coil of one turn. Then magnetic field produced at the centre of the coil,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r}$$

Let *r′* be the radius of the coil formed, when the give wire is bent into a smaller circular coil of *n* turns. Then magnetic field produced at the centre of the coil,

$$B' = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{r'}$$

Now, $n(2\pi r') = 2\pi r$ or $r' = r/n$

$$\therefore \quad B' = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{r/n} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n^2 I}{r} = n^2 B$$

Q. 1.06. An electron revolves in a circular orbit o radius *r* with uniform angular speed ω. From the expression for magnetic field due to a current carrying circula conductor, deduce the expression for magnetic field at th centre of the electron orbit.

Sol. Magnetic field due to current carrying circular conductor of radius *r* is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r} \qquad \text{...(i}$$

The period of revolution of the electron, $T = \frac{2\pi}{\omega}$

The motion of electron in circular orbit is equivalent t current given by

$$I = \frac{e}{T} = \frac{e}{2\pi/\omega} = \frac{e\omega}{2\pi}$$

Substituting for I in equation (*i*), we have

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi}{r} \cdot \frac{e\omega}{2\pi} = \frac{\mu_0 e\omega}{4\pi r}$$

Q. 1.07. Consider the circuit as shown in Fig. 1.23, where APB and AQB are semi-circles. What will be the magnetic field at the centre C of the circular loop ? (*C.B.S.E. 1995*)

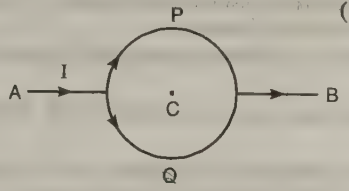

Fig. 1.23

Sol. The magnitude of magnetic field due to current flowing through semi-circular part APB or AQB is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{a}$$

The direction of magnetic field due to the part APB is erpendicular to the paper in inward direction, while that due to part AQB is in outward direction.

Further, the parts APB and AQB produce equal and pposite magnetic fields at the centre C. Hence, the magnetic ield at the centre C is zero.

Q. 1.08. A wire loop is formed by joining two semi-ircular wires of radii r_1 and r_2 as shown in Fig. 1.24. If the oop carries a current I, find the magnetic field at the entre O.

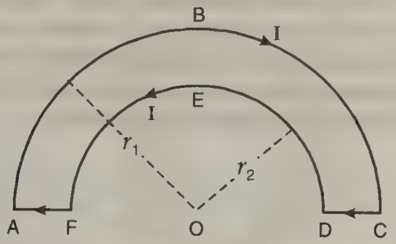

Fig. 1.24

Sol. Magnetic field at O due to semicircular part ABC,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_1} \text{ (inwards)}$$

Magnetic field at O due to semicircular part DEF,

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_2} \text{ (outwards)}$$

The point O lies on the straight parts AF and CD of the vire. Hence, magnetic field due to these straight parts at point) is zero.

Therefore, net magnetic field at point O due to wire loop,

$$B = B_2 - B_1 = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_2} - \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_1}$$

or $$B = \frac{\mu_0}{4\pi} \cdot \pi I \left(\frac{1}{r_2} - \frac{1}{r_1} \right) \textbf{ (in outward direction)}$$

Q. 1.09. A wire loop is formed by joining two semi-ircular wires of radii r_1 and r_2 as shown in Fig. 1.25. If the oop carries a current I, find the magnetic field at the entre O.

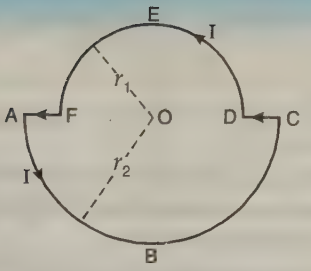

Fig. 1.25

Sol. Magnetic field at O due to semicircular part ABC,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_1} \qquad \text{(outwards)}$$

Magnetic field at O due to semicircular part DEF,

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_2} \qquad \text{(outwards)}$$

Since point O lies on the straight parts AF and CD of the loop, the magnetic field due to these parts at point O is zero.

Therefore, net magnetic field at point O due to wire loop,

$$B = B_1 + B_2 = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_1} + \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r_2}$$

or $$B = \frac{\mu_0}{4\pi} \cdot \pi I \left(\frac{1}{r_1} + \frac{1}{r_2} \right) \textbf{ (in outward direction)}$$

Q. 1.10. Two circular segments of a metallic wire having radii r_1 and r_2 are joined to form a wire loop [Fig. 1.26]. The two segments subtend an angle θ at the centre O. If a current I passes through the wire loop in the direction as shown in figure, find the magnetic field at the centre O.

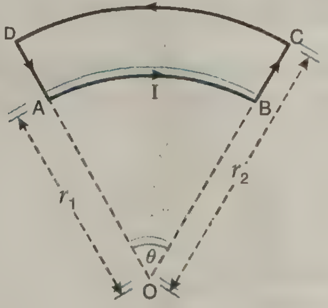

Fig. 1.26

Sol. For a current carrying circular segment of radius *a* subtending an angle θ at its centre, magnetic field* at the centre is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{a} \theta$$

Therefore, magnetic field at O due to circular segment AB,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r_1} \theta \qquad \text{(inwards)}$$

and magnetic field at O due to circular segment CD,

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r_2} \theta \qquad \text{(outwards)}$$

Since point O lies on the straight parts AD and BC of the loop, the magnetic field due to these parts at point O is zero.

Therefore, net magnetic field at point O due to wire loop,

---

*For details, refer to solved numerical problem no. 1.08.

$$B = B_1 - B_2 = \frac{\mu_0}{4\pi}\cdot\frac{I}{r_1}\theta - \frac{\mu_0}{4\pi}\cdot\frac{I}{r_2}\theta$$

or $$B = \frac{\mu_0}{4\pi}\cdot I\theta\left(\frac{1}{r_1} - \frac{1}{r_2}\right)$$ **(in inward direction)**

Q. 1.11. Give expressions for magnetic field due to circular coil (at its centre) and due to long straight wire, when these are carrying currents.

Ans. Magnetic field due to a circular coil at its centre,

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2\pi n I a^2}{(a^2 + x^2)^{3/2}}$$

and magnetic field due to a long straight wire,

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2I}{a}$$

Here, the letters have their usual meanings.

Q. 1.12. What is a solenoid ? Give the magnitude of magnetic field developed at a point well inside a solenoid carrying current. *(H.S.S.C.E. 1998)*

Ans. A solenoid is a circular coil of a large number turns, such that the turns of the solenoid run parallel to it length.

Magnetic field at a point well inside the solenoid,

$$B = \mu_0 n I$$

Here, n is number of turns per unit length of the solenoi

Q. 1.13. An air-core solenoid having N turns of lengt l is carrying a current I ampere.

(*i*) Sketch the pattern of magnetic lines of force in th solenoid.

(*ii*) If an iron core is inserted in it, how is its fiel modified ?

(*iii*) Write down the expression for the magnetic fiel at the centre of the solenoid along its axis.*(C.B.S.E. 1998 S*

Ans. (*i*) For the pattern of magnetic field, refer to Fi 1.12.

(*ii*) The magnetic field lines come closer to each othe

(*iii*) The magnetic field at the centre of the solenoid,

$$B = \mu_0 \frac{N}{l} I$$

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 1.01. Assuming that the earth's magnetic field is due to a large circular loop of current in the interior of the earth, what is the plane of the loop and what is the direction of the current around it ?

Ans. The direction of magnetic field at the centre of the earth is from north to south (It is on the surface of the earth that the magnetic field is from south to north). The magnetic field will be produced along the NS direction [Fig. 1.27], if the circular loop is held in equitorial plane and the current flows in clockwise direction, when seen from north of the earth.

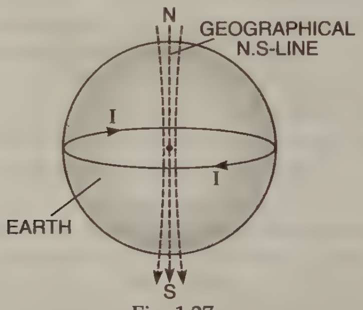

Fig. 1.27

Q. 1.02. Obtain the dimensional formula of (*a*) ε_0 (permittivity of the vacuum) and (*b*) μ_0 (permeability of the vacuum) in terms of M (mass), L (length), T (time) and I (electric current). *(I.I.T. 1998)*

Ans. (*a*) From Coulomb's law in electrostatics, we have

$$F = \frac{1}{4\pi\varepsilon_0}\cdot\frac{q_1 q_2}{r^2}$$

$$\therefore \quad [\varepsilon_0] = \frac{[q_1][q_2]}{[F][r^2]} = \frac{[I\,T][I\,T]}{[M L T^{-2}][L^2]}$$

$$= [M^{-1} L^{-3} T^4 I^2]$$

(*b*) Force per unit length between two infinitely long current carrying conductors,

$$F = \frac{\mu_0}{4\pi}\cdot\frac{2 I_1 I_2}{r}$$

Since F stands for force per unit length, its dimensiona formula is $[M L^0 T^{-2}]$

$$\therefore \quad [\mu_0] = \frac{[F][r]}{[I_1][I_2]} = \frac{[M L^0 T^{-2}][L]}{[I][I]} = [M L T^{-2} I^{-2}]$$

Q. 1.03. A circular branching made from a unifor conductor is connected to a battery as shown i Fig. 1.28. What force will the magnetic field of the curren in the branching exert on the magnetic pole placed at i centre O ? Deduce the result qualitatively.

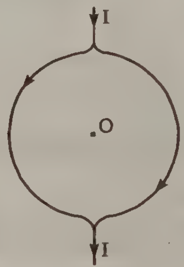

Fig. 1.28

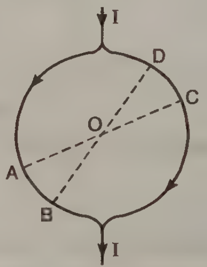

Fig. 1.29

Ans. Suppose that the circular branching is divided int a large number of elementary portions. Consider tw elementary portions AB and CD of equal lengths situate diametrically opposite to each other [Fig. 1.29]. The intensitie of magnetic field produced by the portions AB and CD a point O will be equal in magnitude but opposite in directio The net magnetic field due to the portions AB and CD at poi O will be zero. Similarly, the magnetic fields due to the othe elementary portions will cancel out at point O in pairs. Thu magnetic field due to the complete circular branching at poi O will be zero. Hence, the force on magnetic pole placed a point O will be **zero**.

Q. 1.04. A circular loop of radius R carrying current lies in XY-plane with its centre at origin. What is th magnetic flux through the XY-plane ? *(I.I.T. 199*

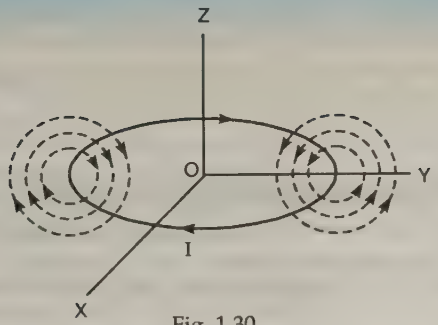

Fig. 1.30

Ans. The magnetic flux in the region of XY-plane lying inside the circular loop will be directed along negative Z-axis, while in the region outside the circular loop, equal magnetic flux will be directed along positive Z-axis as shown in Fig. 1.30. Hence, due to the circular loop, the magnetic flux through the XY-plane will be **zero.**

Q. 1.05. A current I flows along an infinite straight thin-walled pipe [Fig. 1.31]. What is the intensity of the magnetic field inside the pipe ? Assume that current is distributed uniformly along the entire section of the pipe.

Ans. The current flowing along the pipe may be regarded as the sum of many identical currents uniformly distributed over the surface of the pipe. The intensity of magnetic field at any point in the space inside the pipe may be considered as the sum of the intensities of the magnetic fields produced by such linear currents.

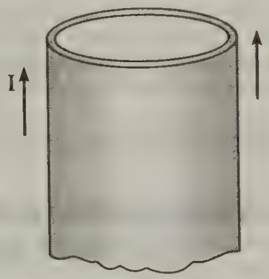

Fig. 1.31

Fig. 1.32 shows the flow of current through the cross-section of the pipe. To find intensity of magnetic field at point P inside the pipe, let us first find the intensities of the magnetic field produced at this point by the linear currents passing through the elementary portions AB and CD.

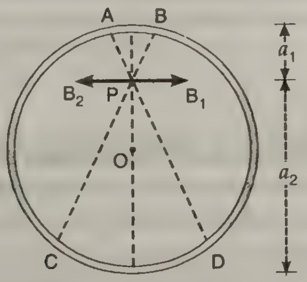

Fig. 1.32

Let I_1 and I_2 be the currents flowing through the portions AB and CD respectively. Obviously,

$$\frac{I_1}{I_2} = \frac{AB}{CD}$$

Let a_1 and a_2 be the distances of the portions AB and CD from the point P. If dB_1 and dB_2 are the intensities of the magnetic fields produced by currents I_1 and I_2 flowing through the elementary portions AB and CD, then

$$dB_1 = \frac{\mu_0}{4\pi} \cdot \frac{2I_1}{a_1} \text{ and } dB_2 = \frac{\mu_0}{4\pi} \cdot \frac{2I_2}{a_2}$$

From the right hand thumb rule, it follows that if dB_1 is towards right, then dB_2 will be towards left. Thus, the resultant intensity of the magnetic field due to portions AB and CD is given by

$$dB = dB_1 - dB_2 = \frac{\mu_0}{4\pi} \cdot \frac{2I_1}{a_1} - \frac{\mu_0}{4\pi} \cdot \frac{2I_2}{a_2}$$

$$= \frac{\mu_0}{2\pi}\left(\frac{I_1}{a_1} - \frac{I_2}{a_2}\right) \qquad ...(ii)$$

Since triangles PAB and PCD are similar,

$$\frac{AB}{CD} = \frac{a_1}{a_2} \qquad ...(iii)$$

From equations (*i*) and (*iii*), we have

$$\frac{I_1}{I_2} = \frac{a_1}{a_2} \text{ or } \frac{I_1}{a_1} = \frac{I_2}{a_2}$$

Setting $\frac{I_1}{a_1} = \frac{I_2}{a_2}$ in equation (*ii*), we have

$$dB = 0$$

Similarly, the contribution to the intensity of the magnetic field at point P by other such pairs of elementary portions of the cross-section of the pipe will be zero. Hence, the intensity of the magnetic field inside an infinite straight pipe carrying current is zero.

Q. 1.06. A current I flows upwards along the inner conductor of a co-axial cable [Fig. 1.33] and returns down along the external shell of the cable. What is the intensity of the magnitude field at points inside the cable ?

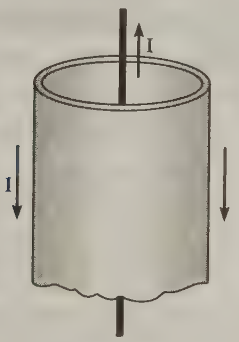

Fig. 1.33

Ans. At a point inside the cable, the magnetic field will be produced only due to the inner conductor. The magnetic field produced due to the external shell of the cable will be zero as proved in conceptual SAQ 1.06.

At a point at distance *a* from the inner conductor, the magnetic field due to the infinitely long inner conductor will be

$$B = \frac{\mu_0}{4\pi} \frac{2I}{a}$$

Q. 1.07. The magnetic field at a point near the centre but outside a current carrying solenoid is zero. Explain, why.

Ans. Consider a vertical plane through the centre of the solenoid and perpendicular to its length. The plane divides the solenoid into two equal parts. At a point outside th solenoid on this plane, corresponding turns of the two halve of the solenoid produce equal and opposite magnetic fields Hence, magnetic field at such a point is zero.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. State and explain Biot-Savart's theorem for a current carrying finite conductor. (*P.S.S.C.E., 2002, 2000*)
2. State Biot-Savart law for magnetic field produced at a point due a small current element. How will you find the direction of magnetic field ? (*P.S.S.C.E. 1996 ; H.S.S.C.E. 1992 ; C.B.S.E. 1991*)
3. State Biot Savart law for the magnetic field produced at a point due to a current element. How will you find the direction of magnetic field ? Define SI unit of magnetic field and give its dimensional formula. (*P.S.S.C.E. 1995*)
4. State Biot Savart law. Use it to obtain an expression for magnetic field at the centre of a current carrying circular loop. (*H.S.S.C.E. 2002 ; C.B.S.E. 1999, 1995*)
5. State Biot-Savart law. Using Biot-Savart law, derive an expression for the magnetic field at the centre of a circular coil of number of turns *n*, radius *r* carrying a current I. (*C.B.S.E. 2002*)
6. Write the expression for Biot-Savart law for the magnetic field due to a small current carrying element. Using the expression, calculate the magnetic field at the centre of current carrying circular coil of radius *r* having *n* number of turns. (*C.B.S.E. 2001 S*)
7. Using Biot Savart law, calculate the magnetic field at the centre of a circular coil. (*C.B.S.E. 2000 ; P.S.S.C.E. 2000, 1999, 1991*)
8. Derive a relation for the magnetic field due to a current carrying circular coil at a point on its axis. (*H.S.S.C.E. 2002, 2001 ; P.S.S.C.E. 1999 S, 1992 H.P.S.S.C.E. 1997*
9. Derive an expression for the magnetic field at the centr of a circular coil of *n* turns. (*I.S.C.E. 1996*
10. State Biot-Savart's law. Use this law to find the magneti field at point on the axis of a circular coil carrying curren (*H.P.S.S.C.E. 2001*
11. Write the expression for Biot-Savart's law for the magneti field due to a small current element. Using this expressior calculate the magnetic field intensity at a point on the axi of a circular current carrying conductor.(*C.B.S.E. 2001 S*
12. State Biot Savart law. Obtain an expression for the magneti field at a point situated at a distance of *x* metre from th centre of a circular coil of *n* turns and of *r* metre radiu carrying a current of I A. (*H.S.S.C.E. 1992*
13. State Ampere's circuital law and prove the Ampere' circuital law for a circular path around a long curren carrying conductor. (*H.P.S.S.C.E. 1998*
14. State and prove Ampere's circuital law. (*H.S.S.C.E. 2001, 1998 S ; P.S.S.C.E. 1995 S*
15. Calculate, using Ampere circuital law, the magnetic fiel at a point well inside a straight solenoid carrying curren
16. Calculate using Ampere's circuital theorem, the magneti field due to an infinitely long wire carrying current I. (*C.B.S.E. 1990*
17. Find the magnetic field intensity for a toroidal solenoid (*H.S.S.C.F. 2000*

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. State the Biot-Savart law. Derive an expression for the magnetic field at a point near a long straight wire carrying a current. (*H.S.S.C.E. 1997 ; Pre degree, Kerala 1994 ; I.S.C.E. 1993*)
2. Using Biot-Savart law, derive an expression for magnetic field intensity produced at a point due to the current flowing through an infinite long straight conductor. (*P.S.S.C.E. 2002, 2000, 1999, 1998 S*)
3. Find the magnetic field intensity at a distance *a* from a current carrying infinitely long, straight, thin metallic conductor. Also draw the sketch of magnetic field. (*P.S.S.C.E. 2000, 1999 S ; H.P.S.S.C.E. 1995*)
4. State Biot Savart's law. Using this law, obtain an expressio for the magnetic field induction at a point situated on th axis of a current carrying circular coil. (*P.S.S.C.E. 2001*
5. State and explain Ampere's circuital law. Derive a expression for magnetic field due to current in a toroid. (*P.S.S.C.E. 2001 ; H.P.S.S.C.E. 1998*
6. State and explain Ampere's circuital law. By applying thi law, obtain an expression for the magnetic field at a poin well inside the solenoid carrying current. (*P.S.S.C.E. 2000, 1999 S, 1999, 1995*

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Magnetic field due to a straight conductor

1. A current of 5 A is flowing south to north in a wire kept along north-south direction. Find the magnetic field due to a 1 cm piece of the wire at a point 2 m north-east from the piece of wire. **[Ans.** $8{\cdot}34 \times 10^{-10}$ T (vertically downwards)]
2. Calculate the magnetic field at a distance of 5 m from an infinite straight conductor carrying a current of 100 A. **[Ans.** 4×10^{-6} T]
3. A current of 10 A is flowing east to west in an infinitel long wire kept along east-west direction. Find magneti field in a horizontal plane at a distance (*a*) 20 cm north an (*b*) 10 cm south from the wire. **[Ans.** (*a*) 10^{-5} T (vertically downwards (*b*) 2×10^{-5} T (vertically upwards)
4. A current of 5 A is flowing east to west in an infinitel long wire kept along east-west direction. Find magneti field in a vertical plane at a distance (*i*) 50 cm below th

wire and (*ii*) 40 cm above the wire.

[**Ans.** (*i*) 2×10^{-6} T (horizontally southwards)
(*ii*) $2{\cdot}5 \times 10^{-6}$ T (horizontally northwards)]

5. Earth's magnetic field is 5×10^{-5} T. A cable is 10 m above the ground. Calculate the current in the cable, so that it may produce a neutral point with earth's magnetic field on the surface of the earth just below it. [**Ans.** 2500 A]

6. Two straight long conductors AOB and COD are perpendicular to each other and carry currents I_1 and I_2 respectively. Find the magnitude of magnetic field at a point P at a distance *a* from the point O in a direction perpendicular to the plane ABCD.

$$\left[\textbf{Ans.}\ \frac{\mu_0}{4\pi}\cdot\frac{2\,(I_1^{\,2}+I_2^{\,2})^{1/2}}{a}\right]$$

7. Calculate the magnetic field induction at the centre of a coil bent in the form of a square of perimeter 40 cm carrying a current of 8 A. (*P.S.S.C.E. 2001*)
[**Ans.** $9{\cdot}04 \times 10^{-5}$ in outward direction]

8. A rectangular loop of metallic wire is of length *a* and breadth *b* and carries a current I. Find the magnitude of magnetic field at the centre O of the loop.

$$\left[\textbf{Ans.}\ \frac{\mu_0}{4\pi}\cdot\frac{8\sqrt{a^2+b^2}\,I}{a\,b}\right]$$

9. A hexagonal loop of a metallic wire is of each side *a* and carries a current I. Find the magnitude of magnetic field at the centre of the loop.

$$\left[\textbf{Ans.}\ \frac{\mu_0}{4\pi}\cdot\frac{4\sqrt{3}\,I}{a}\right]$$

Type B. On Magnetic field due to a circular coil at its centre

10. Calculate the current in a circular coil of radius 5 cm and 100 turns to produce a field of 2×10^{-5} T at its centre.
[**Ans.** $1{\cdot}59 \times 10^{-2}$ A]

11. The electron in a hydrogen atom circles around the proton with a speed of $2{\cdot}18 \times 10^{6}$ m s^{-1} in an orbit of radius $5{\cdot}3 \times 10^{-11}$ m. Calculate (*i*) the equivalent current, (*ii*) magnetic field produced at the proton. Given that $e = 1{\cdot}6 \times 10^{-19}$ C and $\mu_0 = 4\pi \times 10^{-7}$ SI units.
[**Ans.** (*i*)$1{\cdot}047 \times 10^{-3}$ A ; (*ii*) 12·41 T]

12. Calculate the strength of magnetic field due to an electron revolving in a circle of radius 2×10^{-10} m with a speed of 5×10^{6} m s^{-1} at its centre. [**Ans.** 2 T]

13. In Bohr model of hydrogen atom, the electron circulates around the nucleus in a path of radius $5{\cdot}1 \times 10^{-11}$m at a frequency of $6{\cdot}8 \times 10^{15}$ Hz. What is the value of magnetic field set up at the centre of the orbit ?
(*H.S.S.C.E. 1997 S*) [**Ans.** 13·4 T]

14. In an atom, the radius of the electron orbit is 4×10^{-11} m. The electron revolves with frequency of 10^{15} revolutions per second. Charge on the electron is $1{\cdot}6 \times 10^{-19}$ C. Calculate the magnetic field at the centre of the orbit.
[**Ans.** 2·513 T]

15. Two identical coils each of radius *r* and having number of turns *n* are lying in perpendicular planes, such that they have common centre. Find the magnetic field at the centre of the coils, if they carry currents equal to I and $\sqrt{3}$ I respectively.

$$\left[\textbf{Ans.}\ \frac{\mu_0\, n I}{r}\right]$$

16. A semicircular arc of radius 20 cm carries a current of 10 A. Calculate the magnitude of magnetic field at the centre of the arc. (*C.B.S.E. 2002*) [**Ans.** $1{\cdot}57 \times 10^{-5}$ T]

17. An electric current I is flowing through an infinitely long conductor bent into a loop of the shape as shown in Fig. 1.34. Find the magnitude and direction of magnetic field at the centre O of the circular part of the loop.

$$\left[\textbf{Ans.}\ \frac{\mu_0}{4\pi}\cdot\frac{2I}{r}(\pi+1) \text{ in outward direction}\right]$$

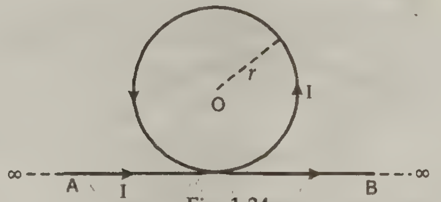

Fig. 1.34

18. An electric current I is flowing through an infinitely long conductor bent into a loop of the shape as shown in Fig. 1.35. Find the magnitude and direction of magnetic field at the centre O of the circular part of the loop.

$$\left[\textbf{Ans.}\ \frac{\mu_0}{4\pi}\cdot\frac{2I}{r}(\pi-1) \text{ in inward direction}\right]$$

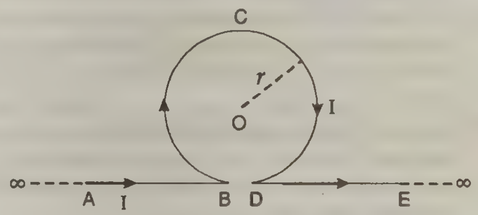

Fig. 1.35

19. An electric current I is flowing through an infinitely long conductor bent into the form as shown in Fig. 1.36. Find the magnitude and direction of magnetic field at the centre of the semi-circular part of the conductor.

$$\left[\textbf{Ans.}\ \frac{\mu_0}{4\pi}\cdot\frac{I}{r}(\pi+2) \text{ in outward direction}\right]$$

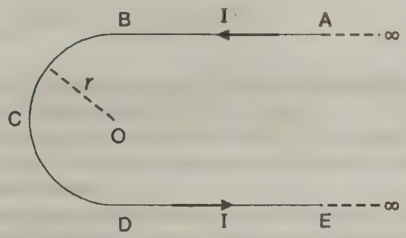

Fig. 1.36

20. A circular segment of radius 0·1 m subtends an angle of 60° at its centre as shown in Fig. 1.37. A current of 6 A is flowing through it. Find the magnitude and direction of the magnetic field produced at the centre O.
[**Ans.** $6{\cdot}28 \times 10^{-6}$ T]

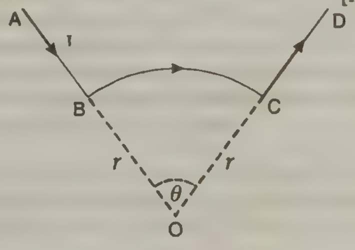

Fig. 1.37

21. A metallic wire is bent into the form as shown in Fig. 1.38 and carries a current I. If point O is the common centre of all the three circular segments of the wires of radii r, $2r$ and $3r$, find the magnetic field at point O.

$$\left[\textbf{Ans. } \frac{\mu_0}{4\pi}\cdot\frac{5\,I}{6\,r}\,\theta \text{ in inward direction}\right]$$

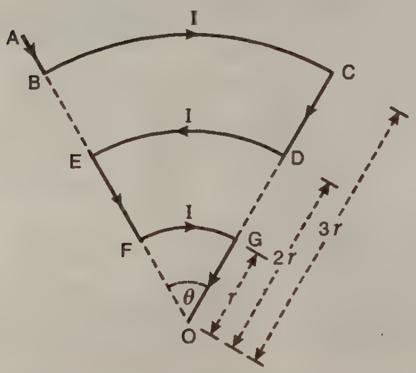

Fig. 1.38

Type C. On Magnetic field due to a circular coil at a point on axis

22. A current of 10 A flows through a circular coil of 50 turns. Calculate the magnetic field at a point situated at a distance of 3 m on the axis from the centre of the coil. The radius of the coil is 10 cm. **[Ans.** $1{\cdot}162 \times 10^{-7}$ T**]**

23. Show that the magnetic field along the axis of a current carrying circular coil of radius a at a distance x ($x << a$) from the centre of the coil is smaller by a factor $1{\cdot}5\, x^2/a^2$ than the field at the centre of the coil.

Type D. On Ampere's circuital law

24. A long straight metallic conductor of radius R carries a current I, which is uniformly distributed over its circular cross-section. Find the magnetic field induction at a point at distance r from the axis of the wire, when the point lies (*a*) outside and (*b*) inside the conductor.

$$\left[\textbf{Ans. } (a)\ \frac{\mu_0}{4\pi}\cdot\frac{2\,I}{r},\quad (b)\ \frac{\mu_0}{4\pi}\cdot\frac{2\,\mu_r\,I\,r}{R^2}\right]$$

Type E. On Magnetic field due to a solenoid

25. Length of a solenoid is 0·2 m and it has 120 turns. Find the magnetic field in its interior, if a current of 2·5 A is flowing through it. Given, $\mu_0 = 4\,\pi \times 10^{-7}$ SI units. **[Ans.** $1{\cdot}885 \times 10^{-3}$ T**]**

26. A solenoid 50 cm long has 4 layers of windings of 350 turns each. If the current carried is 6·0 A, estimate the magnitude of magnetic field (*a*) near the centre of the solenoid on its axis (*b*) near its ends on its axis. (*c*) outside the solenoid near its centre. **[Ans.** (*a*) $2{\cdot}1 \times 10^{-2}$ T ; (*b*) $1{\cdot}05 \times 10^{-2}$ T ; (*c*) zero**]**

27. A solenoid of length 1 m and 3 cm in diameter has five layers of windings of 850 turns each and carries a current of 5 A. What is the magnetic field through a cross-sectional end of the solenoid ? Also calculate the magnetic flux through the cross-section of the solenoid at its centre. **[Ans.** $1{\cdot}335 \times 10^{-2}$ T, $9{\cdot}44 \times 10^{-6}$ Wb**]**

MISCELLANEOUS PROBLEMS

28. Two insulating infinitely long wires are lying mutually perpendicular to each other as shown in Fig. 1.39. If the two wires carry currents I_1 and I_2 as shown in the figure, find the magnetic field at point P (a, b).

$$\left[\textbf{Ans. } \frac{\mu_0}{2\pi}\cdot\left(\frac{I_2}{b}-\frac{I_1}{a}\right) \text{ in inward direction}\right]$$

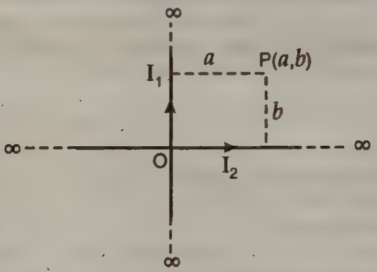

Fig. 1.39

29. Two insulating infinitely long wires are lying mutually perpendicular to each other as shown in Fig. 1.40. If the two wires carry currents I_1 and I_2 as shown in figure, find the locus of the point, where the magnetic field due to two wires is zero.

$$\left[\textbf{Ans. } y = \frac{I_2}{I_1}\,x\right]$$

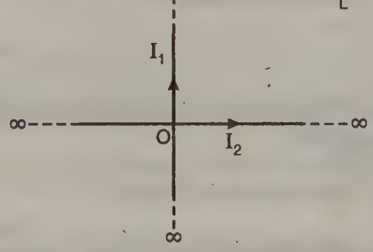

Fig. 1.40

30. A metallic wire carrying a current I is bent into the form as shown in Fig. 1.41. The circular portion ABC of the wire is of radius r and the straight portion AC subtends an angle $2\,\theta$ at the centre O. Find the magnetic field due to the conductor at point O.

$$\left[\textbf{Ans. } \frac{\mu_0}{2\pi}\cdot\frac{I}{r}(\pi-\theta+\tan\theta) \text{ in inward direction}\right]$$

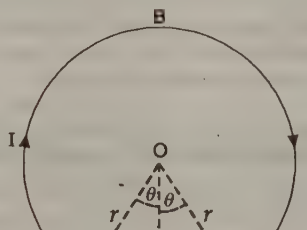

Fig. 1.41

31. A current I is flowing in an infinitely long metallic conductor bent into the form as shown in Fig. 1.42. If the radius of the curved path is r, find the magnetic field at the centre O.

$$\left[\textbf{Ans. } \frac{\mu_0}{4\pi}\cdot\frac{I}{r}\left(\frac{3\pi}{2}+1\right) \text{ in outward direction}\right]$$

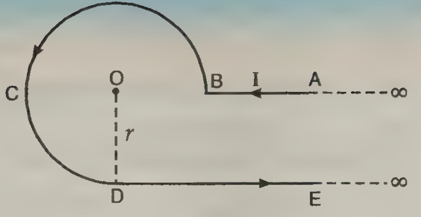

Fig. 1.42

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. $dB = \frac{\mu_0}{4\pi}\cdot\frac{I\,dl\,\sin\theta}{r^2}$

Since the wire is kept along north-south direction and observation point is north-east from the piece of wire, $\theta = 45°$.

$$\therefore \quad dB = \frac{10^{-7}\times 5\times 10^{-2}\sin 45°}{(2)^2}$$

$$= 8{\cdot}34 \times 10^{-10}\ \text{T (Vertically downwards)}$$

2. $B = \frac{\mu_0}{4\pi}\cdot\frac{2I}{a} = \frac{10^{-7}\times 2\times 100}{5} = 4\times 10^{-6}\ \text{T}$

3. (*a*) $B = \frac{\mu_0}{4\pi}\cdot\frac{2I}{a} = \frac{10^{-7}\times 2\times 10}{20\times 10^{-2}} = 10^{-5}\ \text{T (downwards)}$

(*b*) $B = \frac{\mu_0}{4\pi}\cdot\frac{2I}{a} = \frac{10^{-7}\times 2\times 10}{10\times 10^{-2}} = 2\times 10^{-5}\ \text{T (upwards)}$

4. Proceed as in problem no. 3.

5. So as to produce neutral point, magnetic field due to the current carrying cable at that point should be equal and opposite to the earth's magnetic field at that point. Thus,

$$\frac{\mu_0}{4\pi}\cdot\frac{2I}{a} = 5\times 10^{-5} \quad \text{or} \quad \frac{10^{-7}\times 2\times I}{10} = 5\times 10^{-5}$$

or $\quad I = 2500\ \text{A}$

6. Let B_1 and B_2 be magnetic fields produced at point O by conductors AOB and COD respectively. Then,

$$B_1 = \frac{\mu_0}{4\pi}\cdot\frac{2I_1}{a} \quad \text{and} \quad B_2 = \frac{\mu_0}{4\pi}\cdot\frac{2I_2}{a}$$

Since the two conductors are perpendicular to each other, magnetic fields B_1 and B_2 will also be perpendicular to each other. The resultant magnetic field is given by

$$B = \sqrt{B_1^2 + B_2^2} = \left[\left(\frac{\mu_0}{4\pi}\cdot\frac{2I_1}{a}\right)^2 + \left(\frac{\mu_0}{4\pi}\cdot\frac{2I_2}{a}\right)^2\right]^{1/2}$$

or $\quad B = \frac{\mu_0}{4\pi}\cdot\frac{2\,(I_1^2 + I_2^2)^{1/2}}{a}$

7. Proceed as in solved problem no. 1.04.

8. Suppose that current flows through the rectangle loop ABCD as shown in Fig. 1.43. The magnetic fields produced due to all the four sides at the centre O will be perpendicular to the plane of the loop and in outward direction.

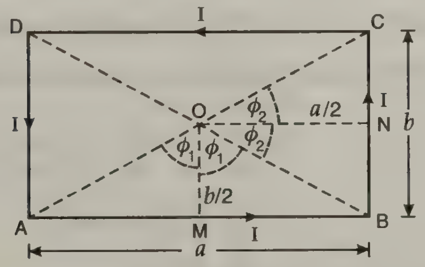

Fig. 1.43

Therefore, total magnetic field at point O,

$$B = B_1 + B_2 + B_3 + B_4,$$

where B_1, B_2, B_3 and B_4 are magnetic fields produced due to sides AB, BC, CD and DA respectively.

$$\text{Now,} \quad B_1 = B_3 = \frac{\mu_0}{4\pi}\cdot\frac{I}{(b/2)}(\sin\phi_1 + \sin\phi_1)$$

$$= \frac{\mu_0}{4\pi}\cdot\frac{4I}{b}\sin\phi_1$$

From right angled Δ OMA, we have

$$\sin\phi_1 = \frac{AM}{OA} = \frac{a/2}{\sqrt{a^2+b^2}/2} = \frac{a}{\sqrt{a^2+b^2}}$$

$$\therefore \quad B_1 = B_3 = \frac{\mu_0}{4\pi}\cdot\frac{4I}{b}\times\frac{a}{\sqrt{a^2+b^2}}$$

Similarly, it can be obtained that

$$B_2 = B_4 = \frac{\mu_0}{4\pi}\cdot\frac{4I}{a}\times\frac{b}{\sqrt{a^2+b^2}}$$

$$\therefore \quad B = \frac{\mu_0}{4\pi}\cdot\frac{4I}{\sqrt{a^2+b^2}}\left[\frac{a}{b}+\frac{b}{a}+\frac{a}{b}+\frac{b}{a}\right]$$

$$= \frac{\mu_0}{4\pi}\cdot\frac{4I}{\sqrt{a^2+b^2}}\times\frac{a^2+b^2+a^2+b^2}{ab}$$

$$\text{or} \quad B = \frac{\mu_0}{4\pi}\cdot\frac{8\sqrt{a^2+b^2}\,I}{ab}$$

9. Suppose that the current flows through the hexagonal loop ABCDEF as shown in the Fig. 1.44.

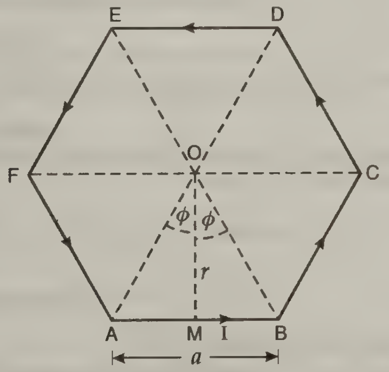

Fig. 1.44

The magnetic field produced at point O due to each of the six sides of the hexagonal loop is same and perpendicular to its plane and in outward direction. If perpendicular distance of point O from the side AB *i.e.* OM = r, then magnetic field at point O due to side AB of the loop,

$$B' = \frac{\mu_0}{4\pi} \cdot \frac{I}{r} (\sin\phi + \sin\phi) = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r} \sin\phi$$

Here $\phi = 30°$

Also, from right angled Δ AMO, we have

$$\tan\phi = \frac{AM}{OM} \quad \text{or} \quad \tan 30° = \frac{a/2}{r}$$

or $$r = \frac{a}{2\tan 30°} = \frac{\sqrt{3}\,a}{2}$$

∴ $$B' = \frac{\mu_0}{4\pi} \cdot \frac{2I}{\sqrt{3}\,a/2} \sin 30° = \frac{\mu_0}{4\pi} \cdot \frac{2I}{\sqrt{3}\,a}$$

Hence, magnetic field due to the whole hexagonal loop,

$$B = 6\,B' = \frac{\mu_0}{4\pi} \cdot \frac{4\sqrt{3}\,I}{a}$$

10. Proceed as in solved problem no. 1.05.

11. Proceed as in solved problem no. 1.06.

12. Proceed as in solved problem no. 1.06.

13. If ν is frequency of revolution of electron, then

$$I = e\nu$$

Now, proceed as in solved problem no. 1.06.

14. Proceed as in problem no. 13.

15. Let B_1 and B_2 be magnetic fields produced by the two coils. Then,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I_1}{r} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{r} = \frac{\mu_0 n I}{2r}$$

and $$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I_2}{r} = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n \times \sqrt{3}\,I}{r} = \frac{\sqrt{3}\,\mu_0 n I}{2r}$$

Since the planes of the two coils are perpendicular to each other, magnetic fields B_1 and B_2 produced by them will also be perpendicular to each other. The resultant magnetic field is given by

$$B = \sqrt{B_1^2 + B_2^2} = \left[\left(\frac{\mu_0 n I}{2r}\right)^2 + \left(\frac{\sqrt{3}\,\mu_0 n I}{2r}\right)^2\right]^{1/2}$$

$$= \frac{\mu_0 n I}{2r}(1+3)^{1/2} = \frac{\mu_0 n I}{r}$$

16. Proceed as in solved problem no. 1.07.

17. Let B_1 and B_2 be magnetic fields produced due to circular and straight parts of the loop. Then,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r}$$ (perpendicular to the plane of loop and in outward direction)

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r}$$ (perpendicular to the plane of loop and in outward direction)

Since B_1 and B_2 are in same direction, total magnetic field produced by the loop,

$$B = B_1 + B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r} + \frac{\mu_0}{4\pi} \cdot \frac{2I}{r}$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{2I}{r}(\pi + 1)$$ **in outward direction**

18. Proceed as in problem no. 17.

Here, B_1 will be perpendicular to plane of loop and in inward direction, while B_2 will be in outward direction. Therefore,

$$B = B_1 - B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r}(\pi - 1)$$ **in inward direction**

19. Let B_1, B_2 and B_3 be the magnetic fields produced at p
O by straight part AB, semicircular part BCD and strai
part DE of the current carrying conductor ABCDE. Th

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r}(\sin\phi_1 + \sin\phi_2)$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I}{r}(\sin 90° + \sin 0°)$$

or $$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r},$$ (perpendicular to the pl
and in outward directi

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r},$$ (perpendicular to the pl
and in outward directi

and $$B_3 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r}(\sin\phi_1 + \sin\phi_2)$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I}{r}(\sin 90° + \sin 0°)$$

or $$B_3 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r}$$ (perpendicular to the pl
and in outward durecti

Therefore, total magnetic field produced by the conduc

$$B = B_1 + B_2 + B_3 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r} + \frac{\mu_0}{4\pi} \cdot \frac{\pi I}{r} + \frac{\mu_0}{4\pi} \cdot \frac{I}{r}$$

or $$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{r}(\pi + 2)$$ **in outward direction**

20. Let B_1, B_2 and B_3 be the magnetic fields produced at p
O by the straight part AB, circular part BC and straight
CD of the current carrying conductor ABCD. Since p
O lies on straight parts AB and CD,

$$B_1 = B_3 = 0$$

Further, as circular segment BC subtends angle θ at p
O,

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{r} \times \frac{\theta}{2\pi} = \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{r}$$

$$= \frac{10^{-7} \times 6 \times \pi/3}{0 \cdot 1} = 6 \cdot 28 \times 10^{-6}\ \text{T}$$

Hence, total magnetic field at point O,

$$B = B_1 + B_2 + B_3 = 0 + 6{\cdot}28 \times 10^{-6} + 0$$

$$= \mathbf{6{\cdot}28 \times 10^{-6}\ T}$$

21. For the reason explained in problem no. 20, magnetic fi
produced at point O by the straight parts AB, CD, EF
GO of the conductor will be zero. Let B_1, B_2 and B
magnetic fields produced at point O due to circular p
BC, DE and FG respectively. Then,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{3r},$$ (in inward direction)

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{2r}$$ (in outward direction)

and $$B_3 = \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{r}$$ (in inward direction)

Therefore, total magnetic field produced by the conduc

$$B = B_1 - B_2 + B_3$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{3r} - \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{2r} + \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{r}$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I\theta}{r}\left(\frac{1}{3} - \frac{1}{2} + 1\right)$$

or $$B = \frac{\mu_0}{4\pi} \cdot \frac{5I\theta}{6r}$$ **(in inward direction)**

22. Proceed as in solved problem no. 1.10.

23. Let B be magnetic field at a point at distance x from the centre of the coil and B_0, at the centre of the coil.

Then, $$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I a^2}{(a^2+x^2)^{3/2}} \quad \text{...(i)}$$

and $$B_0 = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I}{a} \quad \text{...(ii)}$$

It follows that the magnetic field at a point on the axis of the coil is smaller than that at its centre by an amount, $B_0 - B$. Hence, the factor by which B is smaller than B_0,

$$n = \frac{B_0 - B}{B_0} = 1 - \frac{B}{B_0}$$

Using equations (*i*) and (*ii*), we have

$$n = 1 - \frac{\mu_0}{4\pi} \cdot \frac{2\pi I a^2}{(a^2+x^2)^{3/2}} \times \frac{4\pi}{\mu_0} \cdot \frac{a}{2\pi I}$$

$$= 1 - \frac{a^3}{(a^2+x^2)^{3/2}} = 1 - \frac{a^3}{a^3(1+x^2/a^2)^{3/2}}$$

$$= 1 - \left(1 + \frac{x^2}{a^2}\right)^{-3/2} = 1 - \left(1 - \frac{3}{2}\frac{x^2}{a^2} + \ldots\right)$$

$$= 1 - \left(1 - \frac{3}{2}\frac{x^2}{a^2}\right) = \frac{3}{2}\frac{x^2}{a^2} = 1.5\frac{x^2}{a^2}$$

24. Proceed as in solved problem no. 1.12.

25. $$B = \mu_0 n I = \mu_0 \frac{N}{l} I = 4\pi \times 10^{-7} \times \frac{120}{0.2} \times 2.5$$
$$= 1.885 \times 10^{-3}\ \text{T}$$

26. **(a)** Proceed as in solved problem no. 1.14

(b) Magnetic field near the end on axis is equal to one half of that at the centre of the solenoid.

(c) Outside the solenoid, magnetic field is zero.

For explanation, refer to conceptual SAQ 1.07.

27. **(a)** Proceed as in problem no. 26 (*b*)

(b) Magnetic flux, $\phi = B_{end} \times \frac{\pi D^2}{4}$

28. $$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1}{a} \text{ (in inward direction)}$$

and $$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2 I_2}{a} \text{ (in outward direction)}$$

As $b < a$, $B_2 > B_1$

Therefore, net magnetic field at point P,

$$B = B_2 - B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2 I_2}{b} - \frac{\mu_0}{4\pi} \cdot \frac{2 I_1}{a}$$

$$= \frac{\mu_0}{2\pi}\left(\frac{I_2}{b} - \frac{I_1}{a}\right)$$

29. Let magnetic field be zero at a point, whose coordinates are (x, y).

Then, $$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1}{x} \text{ (in inward direction)}$$

and $$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2 I_2}{y} \text{ (in outward direction)}$$

As magnetic field at the observation point is zero,

$B_1 = B_2$ (in magnitude)

or $$\frac{\mu_0}{4\pi} \cdot \frac{2 I_1}{x} = \frac{\mu_0}{4\pi} \cdot \frac{2 I_2}{y} \quad \text{or} \quad y = \frac{I_2}{I_1} x$$

30. Let B_1 and B_2 be magnetic fields produced at point O due to circular part ABC and straight part AC of the current carrying metallic wire.

The circular part ABC of the metallic wire subtends an angle $2\pi - 2\theta$ at the centre O.

$$\therefore \quad B_1 = \frac{\mu_0}{4\pi} \cdot \frac{I(2\pi - 2\theta)}{r}$$

$$= \frac{\mu_0}{2\pi} \cdot \frac{I}{r}(\pi - \theta) \quad \text{(in inward direction)}$$

Let ON = a. Then,

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{I}{a}(\sin\theta + \sin\theta)$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{2I}{a}\sin\theta \quad \text{(in inward direction)}$$

From right angled Δ ANO, we have

ON = OA cos θ or $a = r\cos\theta$

$$\therefore \quad B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2I}{r\cos\theta}\sin\theta = \frac{\mu_0}{2\pi} \cdot \frac{I}{r}\tan\theta$$

Hence, total magnetic field at point O,

$$B = B_1 + B_2 = \frac{\mu_0}{2\pi} \cdot \frac{I}{r}(\pi - \theta) + \frac{\mu_0}{2\pi} \cdot \frac{I}{r}\tan\theta$$

$$= \frac{\mu_0}{2\pi} \cdot \frac{I}{r}(\pi - \theta + \tan\theta) \text{ in inward direction}$$

31. Let B_1, B_2 and B_3 be magnetic fields produced at point O due to straight part AB, circular part BCD and straight part DE of the current carrying conductor.

As point O lies on the straight part AB,

$B_1 = 0$

The circular part BCD subtends an angle of 270° *i.e.* $\frac{3\pi}{2}$ at the centre O. Therefore,

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r} \times \frac{3\pi}{2} \text{ (in outward direction)}$$

Also, $$B_3 = \frac{\mu_0}{4\pi} \cdot \frac{I}{r}(\sin 90° + \sin 0°) = \frac{\mu_0}{4\pi} \cdot \frac{I}{r}(1+0)$$

$$= \frac{\mu_0}{4\pi} \cdot \frac{I}{r} \text{ (in outward direction)}$$

Therefore, resultant magnetic field at point O,

$$B = B_1 + B_2 + B_3 = 0 + \frac{\mu_0}{4\pi} \cdot \frac{I}{r} \times \frac{3\pi}{2} + \frac{\mu_0}{4\pi} \cdot \frac{I}{r}$$

or $$B = \frac{\mu_0}{4\pi} \cdot \frac{I}{r}\left(\frac{3\pi}{2} + 1\right) \text{ in outward direction}$$

CHAPTER

2

Motion of Charged Particle

2.01. MOTION OF A CHARGED PARTICLE INSIDE ELECTRIC FIELD

Suppose that a uniform electric field is set up in the plane of paper along OY by applying potential difference between two plates parallel to horizontal [Fig. 2.01]. If V is the potential difference between the parallel plates held at a distance d apart, then strength of the electric field,

$$E = \frac{V}{d} \qquad ...(2.01)$$

Suppose that a positively charged particle having charge q and mass m enters the electric field along OX (normal to the direction of electric field) with velocity v. Due to the action of the electric field, the path of the charged particle no longer remains straight. Suppose that the charged particle moves along the curved path OA. On emerging out of the electric field, it will move along the straight path AB, tangent to the curved path OA at point A. As the particle moves along path OA, it covers a horizontal distance OQ = x and a vertical distance QA = y.

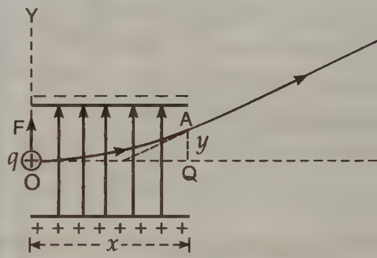

Fig. 2.01

Due to the electric field, force acts on the charged particle only along OY and it does not experience any force along OX. Therefore, the horizontal distance x is covered by the charged particle with uniform velocity v. Therefore, time taken by the charged particle to cover the horizontal distance OQ = x is given by

$$t = \frac{x}{v}$$

Along vertical direction OY, the charged particle has zero initial velocity. Due to electric field, it experiences a force,

$$F = qE \qquad \text{(along OY)}$$

and the acceleration in the path of charged particle along OY is given by

$$a = \frac{qE}{m}$$

The distance y covered along OY is given by

$$y = (0)\,t + \frac{1}{2}at^2 = \frac{1}{2}\frac{qE}{m}\cdot\left(\frac{x}{v}\right)^2$$

or

$$y = \frac{qE}{2mv^2}x^2 \qquad ...(2.02)$$

This is the equation of a parabola and hence inside the electric field, a charged particle moves along the curved path OA, which is ***parabolic*** in nature.

Key point

A charge always experiences a force
electric field, whether it is stationary o
in motion.

2.02. FORCE ON A CHARGE MOVING IN A MAGNETIC FIELD

Consider that a charge $+q$ is moving inside the magnetic field of strength $\vec{B}$. Suppose that the magnetic field acts along Z-axis, while the charge $+q$ moves with velocity $\vec{v}$ in YZ-plane making angle θ with the direction of $\vec{B}$ and as shown in Fig. 2.02.

As such, the charge $+q$ experiences force $\vec{F}$ along X-axis. It is found that the magnitude of the force is :

(*i*) *directly proportional to the magnitude of the strength of magnetic field i.e.*

$$F \propto B$$

(*ii*) *directly proportional to the magnitude of the charge i.e.*

$$F \propto q$$

(*iii*) *directly proportional to the component of velocity along a direction perpendicular to the direction of magnetic field i.e.*

$$F \propto v \sin\theta$$

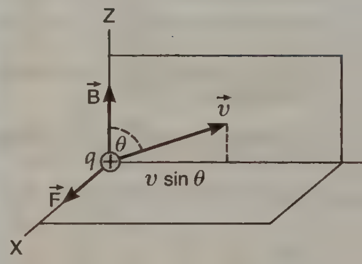

Fig. 2.02

Combining the three factors, we have

$$F \propto B\,q\,v \sin\theta$$

or $$F = k\,B\,q\,v \sin\theta,$$

here k is the constant of proportionality. In SI, when B is measured in tesla, q in ulomb and v in metre second^{-1}, the value of the constant k is found to be 1. herefore,

$$F = B\,q\,v \sin\theta, \qquad ...(2.03)$$

The force on a charged particle moving inside a magnetic field is called *agnetic Lorentz force*. The equation (2.03) gives the magnitude of the magnetic orentz force on a charged particle. In vector notation,

$$\vec{F} = q(\vec{v} \times \vec{B}) \qquad ...(2.04)$$

The equation (2.04) gives both the magnitude and the direction of the magnetic orentz force on the charged particle moving inside the magnetic field. Thus, if the harged particle moves along Y-axis with velocity $\vec{v}$ and the magnetic field $\vec{B}$ is irected along Z-axis [Fig. 2.03], then force on the charge $+q$ acts in the direction of $\vec{v} \times \vec{B})$ *i.e.* along X-axis.

Key point

The force on a charge moving inside a magnetic field results due to interaction between the magnetic field produced by the moving charge (which is equivalent to current) and the applied field.

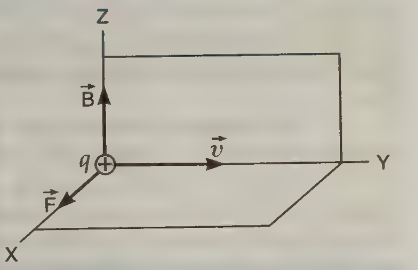

Fig. 2.03

Special cases. Let us consider the following cases :

1. ***When the charged particle is at rest.*** If the charged particle is at rest, hen $v = 0$. From equation (2.03), the force on charged particle,

$$F = B\,q\,(0) \sin\theta = 0$$

Thus, a charged particle at rest inside the magnetic field does not experience ny force due to a magnetic field.

2. ***When the charged particle moves parallel to the magnetic field.*** If $\vec{v}$ is arallel to $\vec{B}$, then $\theta = 0°$ or 180°. Then, from equation (2.03), the force on the charged article,

$$F = B\,q\,v\,(0) = 0 \qquad (\because \sin 0° = \sin 180° = 0)$$

In other words, a charged particle experiences force inside a magnetic field nly if it does not move parallel to the direction of the magnetic field.

Key point

1. A stationary charge does not experience any force in magnetic field.
2. A moving charge experiences force in magnetic field, provided it is not moving parallel to the direction of the field.

3. ***When the charged particle moves perpendicular to the magnetic field.*** If $\vec{v}$ is erpendicular to $\vec{B}$, then $\theta = 90°$. In that case, from equation (2.03), the force xperienced by the charged particle,

$$F = B\,q\,v\,(1) = B\,q\,v \textit{ (maximum)} \qquad (\because \sin 90° = 1)$$

Unit of strength of magnetic field. In SI, the unit of strength of magnetic field s **tesla (T).** The equation (2.03) may be used to define the unit of magnetic field as xplained below :

From equation (2.03), we have

$$B = \frac{F}{q\,v \sin\theta}$$

Therefore, $$\mathbf{1\ tesla\ (T)} = \frac{\mathbf{1\,N}}{\mathbf{1\,C \times 1\,m\,s^{-1} \times 1}} = \mathbf{1\,N\,A^{-1}\,m^{-1}} \qquad (\because C\,s^{-1} = A)$$

The strength of magnetic field at a point is called one tesla, if a charge of one coulomb, when moving with a velocity of 1 m s^{-1} along a direction perpendicular to the direction of the magnetic field, experiences a force of one newton.

Note. 1. The strength of magnetic field at a point is also measured as the magnetic flux crossing per unit area normally at that point.

The strength of magnetic field at a point is called one tesla, if a magnetic flux of one weber crosses an area of 1 m^2 along normal to the surface.

Thus $$\mathbf{1\ tesla\ (T) = 1\ weber\ metre^{-2}\ (Wb\ m^{-2})}$$

2. The strength of magnetic field is commonly expressed as **gauss (G).**

$$\mathbf{1\ gauss\ (G) = 10^{-4}\ tesla\ (T)}$$

2.03. LORENTZ FORCE

When a charge q moves with velocity $\vec{v}$ inside magnetic field of strength $\vec{B}$, then force on the charge,

$$\vec{F} = q(\vec{v} \times \vec{B})$$

It is called ***magnetic Lorentz force*** on the charge due to its motion inside the magnetic field.

If in addition to magnetic field of strength $\vec{B}$, an electric field of strength $\vec{E}$ also acts, then total force on the charge q is given by

$$\vec{F} = q\vec{E} + q(\vec{v} \times \vec{B}) \qquad ...(2.05)$$

The force $\vec{F}$ given by equation (2.05) is called the ***total Lorentz force*** on the charge q.

Key point

If a charge is moving along the directio of electric field, only magnitude of it velocity is affectd. The direction o motion is affected, when the charge enter the field obliquely.

The following points may be noted about Lorentz force :

1. The magnetic Lorentz force is in the direction of vector $\vec{v} \times \vec{B}$ *i.e.* perpendicular to both the direction of motion of charge and the direction of magnetic field.

2. The magnetic Lorentz force does no work on the charge, as it always acts perpendicular to the motion of the charge.

3. Magnetic Lorentz force on a charge, in addition to the strength of the magnetic field, depends upon its velocity also, whereas force on the charge due to electric field depends only on the strength of the electric field. These facts can be used to tell whether the charge is moving inside an electric or magnetic field as discussed below :

(a) *If at a point, a charge moving in a field experiences force, which varies directly as the strength of the field (but does not depend upon the velocity of the charge), then the charge is moving inside electric field only.*

(b) *If at a point, a charge moving in a field experiences force, which varies directly as the strength of the field as well as its velocity (becomes zero, when charge is at rest), then the charge is moving inside magnetic field only.*

Key point

In a field, if the force experienced by charge depends only upon the field an does not depend upon the velocity of th particle, the field must be electric i nature.

2.04 MOTION OF A CHARGED PARTICLE INSIDE A UNIFORM MAGNETIC FIELD

When a charged particle having charge q moves inside a magnetic field $\vec{B}$ with velocity $\vec{v}$, it experiences a force given by

$$\vec{F} = q(\vec{v} \times \vec{B}) \qquad ...(2.06)$$

The direction of force on the charged particle due to magnetic field is always in a direction perpendicular to both its velocity $\vec{v}$ and the magnetic field $\vec{B}$. Let us study the motion of the charged particle inside magnetic field in the following two cases :

***(a)* When $\vec{v}$ is perpendicular to $\vec{B}$**. Consider that the uniform magnetic field of strength $\vec{B}$ is directed along OZ and the charged particle is moving in XY-plane. Suppose that at any instant, the charged particle is at point A, so that the vectors representing its velocity $\vec{v}$ and the magnetic field $\vec{B}$ are perpendicular to each other as shown in Fig. 2.04. For the orientations of $\vec{v}$ and $\vec{B}$ at point A, the equation (2.06) tells that the force $\vec{F}$ on the charged particle acts along AO *i.e.* along perpendicular to both $\vec{v}$ and $\vec{B}$. Since the force $\vec{F}$ acts on the charged particle perpendicular to its velocity, *it does not do any work.* Hence, magnitude of the velocity of the charged particle remains constant and the force on the charged particle brings about a change only in the direction of the velocity of the charged particle. In other words, the force $\vec{F}$ on the charged particle acts as the centripetal force and makes it to move along a circular path. At points B and C in the XY-plane, the charged particle experiences force along BO and CO respectively. If m is the mass of the charged particle and r, the radius of the circular path followed by it, then

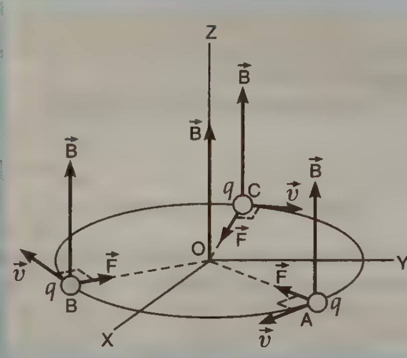

Fig. 2.04

$$|q(\vec{v} \times \vec{B})| = \frac{mv^2}{r} \qquad ...(2.07)$$

Since $\vec{v}$ and $\vec{B}$ are at right angles to each other, we have

$$|q(\vec{v} \times \vec{B})| = Bqv \qquad ...(2.08)$$

Therefore, from equations (2.07) and (2.08), we have

$$\mathrm{B}\,q\,v = \frac{m\,v^2}{r}$$

or
$$r = \frac{m\,v}{\mathrm{B}\,q} \qquad \text{...(2.09)}$$

It follows that

(*i*) *faster the particle moves (v large), the larger is the radius of circular path and*
(*ii*) *heavier the charged particle (m large), the larger is the radius of the circular path.*

The period of circular motion of the charged particle is given by

$$\mathrm{T} = \frac{2\pi r}{v} = \frac{2\pi}{v} \times \frac{m\,v}{\mathrm{B}\,q}$$

or
$$\mathrm{T} = \frac{2\pi m}{\mathrm{B}\,q} \qquad \text{...(2.10)}$$

The angular frequency of the charged particle moving inside the uniform agnetic field is given by

$$\omega = \frac{2\pi}{\mathrm{T}} = 2\pi \Big/ \frac{2\pi m}{\mathrm{B}\,q}$$

or
$$\omega = \frac{\mathrm{B}\,q}{m} \qquad \text{....(2.11)}$$

From equations (2.10) and (2.11), it follows that the period of the circular motion nd the angular frequency of a charged particle moving in a uniform magnetic field *either depends upon the magnitude of its velocity nor upon the radius of the circular path.* his fact is made use of to accelerate positive ions and such an accelerator is called *yclotron*. The angular frequency ω is oftenly called ***cyclotron frequency***.

(*b*) **When $\vec{v}$ and $\vec{\mathrm{B}}$ are inclined to each other.** Suppose that at any instant, the harged particle is moving with velocity $\vec{v}$ inside the uniform magnetic field $\vec{\mathrm{B}}$ naking an angle θ with the direction of the magnetic field as shown in Fig. 2.05.

The velocity $\vec{v}$ of the charged particle can be resolved into the following two omponents :

(*i*) The component v_B along the direction of the magnetic field *i.e.* along OZ. It is given by

$$v_\mathrm{B} = v\cos\theta$$

(*ii*) The component v_n along normal to the direction of magnetic field *i.e.* in XY-plane. It is given by

$$v_n = v\sin\theta$$

As the magnetic field acts perpendicular to the velocity component v_n, the harged particle moves along a circular path. Therefore, as obtained in equation 2.09), the radius of the circular path followed by the charged particle is given by

$$r = \frac{m\,v_n}{\mathrm{B}\,q} = \frac{m\,v\sin\theta}{\mathrm{B}\,q} \qquad \text{...(2.12)}$$

The period of the circular path is given by

$$\mathrm{T} = \frac{2\pi r}{v_n} = \frac{2\pi}{v\sin\theta} \times \frac{m\,v\sin\theta}{\mathrm{B}\,q}$$

or
$$\mathrm{T} = \frac{2\pi m}{\mathrm{B}\,q} \qquad \text{...(2.13)}$$

It is the same expression as given by equation (2.10). It implies that the period of revolution of the charged particle remains same, whether $\vec{v}$ is parallel to or nclined to $\vec{\mathrm{B}}$.

As the charged particle moves along circular path in XY-plane due to the velocity component v_n, it also advances linearly along OZ due to the velocity component v_B. As a result, the charged particle will move along the path as shown n Fig. 2.06. Such a path is called ***helical path***.

Key point

When a charge moves inside the magnetic field, magnitude of its velocity is not affected by the field. However, direction of motion of the charge changes continuously and it moves along a circular path..

Key point

A charge follows circular path, when it enters a magnetic field in a direction perpendicular to the field. In case charge enters the field obliquely, it follows helical path due to component of its velocity along the field.

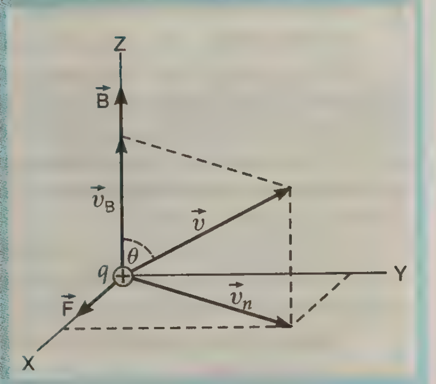

Fig. 2.05

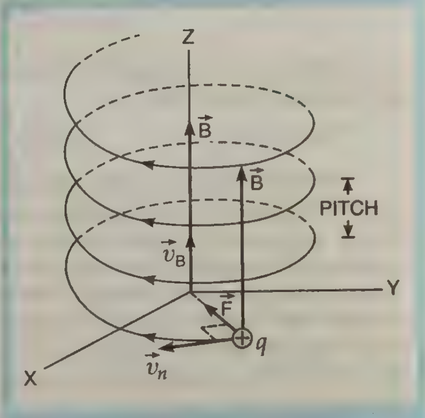

Fig. 2.06

The distance travelled by the charged particle, along the direction of magnetic field in a time it completes one revolution, is called ***pitch of the helical path.*** Therefore,

$$\text{pitch of the helical path} = v_B \times T = v \cos\theta \times \frac{2\pi m}{Bq}$$

or

$$\text{pitch} = \frac{2\pi m v \cos\theta}{Bq} \qquad \text{...(2.14)}$$

Note. Pitch of the helical path is equal to the spacing between its two consecutive circular paths.

2.05. CYCLOTRON

A cyclotron is used for accelerating positive ions, so that they acquire energy large enough to carry out nuclear reactions. Another accelerator, called ***linear accelerator***, was also developed for this purpose. However, it has a main drawback that its length would very large, if the positive ions are to be accelerated to a very high energy. It is because, the cylindrical tubes of increasing lengths have to be used, as the positive ions gain more and more energy.

Cyclotron was designed by Lawrence and Livingstone in 1931 in order to overcome the drawbacks of the linear accelerator. In a cyclotron, the positive ions cross again and again the same alternating (radio frequency) electric field and thereby gain the energy. It is achieved by making them to move along spiral path under the action of a strong magnetic field. It is also known as ***magnetic resonance accelerator.***

Principle. It is based on the principle that *a positive ion can acquire sufficiently large energy with a comparatively smaller alternating potential difference by making them to cross the same electric field time and again by making use of a strong magnetic field.*

Construction. It consists of two D-shaped hollow semicircular metal chambers D_1 and D_2, called *dees*. The two dees are placed horizontally with a small gap separating them. The dees are connected to the source of high frequency electric field. The dees are enclosed in a metal box containing a gas at a low pressure of the order of 10^{-3} mm mercury. The whole apparatus is placed between the two poles of a strong electromagnet NS as shown in Fig. 2.07. The magnetic field acts perpendicular to the plane of the dees.

The positive ions are produced in the gap between the two dees by the ionisation of the gas. To produce proton, hydrogen gas is used ; while for producing alpha-particles, helium gas is used.

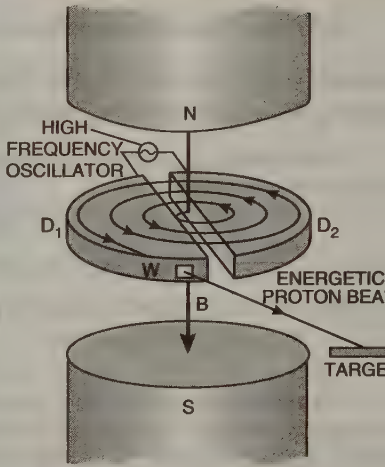

Fig. 2.07

Theory. Consider that a positive ion is produced at the centre of the gap at the time, when the dee D_1 is at positive potential and the dee D_2 is at a negative potential. The positive ion will move from dee D_1 to dee D_2. As the magnetic field acts normally to the motion of the positive ion, the positive ion experiences force. The force on the positive ion due to magnetic field provides the centripetal force to the positive ion and it is deflected along a circular path. If B is strength of the magnetic field and m, v and q, are respectively the mass, velocity and charge of the positive ion, then

$$B q v = \frac{m v^2}{r} \qquad \text{...(2.15)}$$

Here, r is the radius of the semi-circular path along which the positive ion will move inside the dee D_2.

Thus,

$$r = \frac{m v}{B q} \qquad \text{...(2.16)}$$

After moving along the semi-circular path inside the dee D_2, the positive ion reaches the gap between the dees. At this stage, the polarity of the dees just reverses due to alternating* electric field *i.e.* dee D_1 becomes negative and dee D_2 becomes positive. The positive ion again gains the energy, as it is attracted by the dee D_1. After moving along the semi-circular path inside the dee D_1, the positive ion again reaches the gap and it again gains the energy. This process repeats itself time and again. It is because, *the positive ion spends the same time inside a dee irrespective of its velocity or the radius of the circular path.* It can be proved as below :

---

*The alternating electric field used is of radio-frequency.

The time spent inside a dee to cover semi-circular path,

$$t = \frac{\text{length of the semi circular path}}{\text{velocity}} = \frac{\pi r}{v}$$

Using equation (2.16), we have

$$t = \frac{\pi m}{Bq} \qquad ...(2.17)$$

As required, the time which a positive ion of mass m and charge q spends inside dee is indeed independent of its velocity and radius of the semi-circular path. It ay again be pointed out that decrease in time spent inside a dee due to increasing elocity of positive ions is exactly compensated by the increase in length of the semi-rcular path. Due to this condition, the positive ion always crosses the alternating ectric field across the gap in correct phase.

Key point ✓

Time period of revolution of a charged particle inside the dees (magnetic field) is independent of the speed and radius of the circular path described. It depends upon the value of its charge, mass and strength of the field.

Cyclotron frequency. Under the action of the given magnetic field (B fixed), the ven positive ion (e/m fixed) will cover the semi-circular path in a fixed time only, t in equation (2.17) is equal to $\frac{T}{2}$ where T is the time period of the electric field.

$$\therefore \qquad \frac{T}{2} = \frac{\pi m}{Bq}$$

$$\text{or} \qquad T = \frac{2\pi m}{Bq}$$

The cyclotron angular frequency, $\omega = \frac{2\pi}{T} = \frac{Bq}{m}$ ...(2.18)

Also, cyclotron frequency, $\nu = \frac{1}{T} = \frac{Bq}{2\pi m}$ ...(2.19)

It is also known as ***magnetic resonance frequency*** (non-relativistic).

Maximum energy of the positive ions. Let v_{max} be the velocity acquired by the ositive ions, when it moves along the largest circular path *i.e.* path of radius equal the radius R of the dees. Then,

Key point ✓

A charged particle gets accelerated only due to the electric field. There is no effect of magnetic field on velocity (or kinetic energy) of the charged particle. The magnetic field simply makes the charged particle to cross the electric field again and again by making it to move along circular path.

$$B q v_{max} = \frac{m v_{max}^2}{R}$$

$$\text{or} \qquad v_{max} = \frac{BqR}{m} \qquad ...(2.20)$$

Therefore, maximum kinetic energy gained by the positive ion,

$$E_{max} = \frac{1}{2} m v_{max}^2 = \frac{1}{2} m \left(\frac{BqR}{m}\right)^2$$

$$\text{or} \qquad E_{max} = \frac{1}{2}\frac{B^2 q^2 R^2}{m} \qquad ...(2.21)$$

The maximum energy acquired by the positive ion can be expressed in nother form as given below :

If V is the potential difference applied between the dees and N is the number f times, the positive ion crosses the gap between the dees before leaving the dees, en

$$E_{max} = N(Vq) \qquad ...(2.22)$$

Obviously, $N = 2n$, where n is the number of rotations completed by the positive n before the radius of its circular path becomes equal to that of the dees.

Limitations of cyclotron. 1. When a charged particle is accelerated, its mass so starts increasing with increase in its speed. When its speed becomes comparable that of light, the mass of the charged particle becomes quite large as compared its rest mass. If m_0 is rest mass, then mass of charged particle when moving with eed v is given by

$$m = \frac{m_0}{\sqrt{1 - v^2/c^2}}$$

Substituting for m in equation (2.17), we have

time spent inside a dee, $t = \dfrac{\pi m_0}{qB\sqrt{1 - v^2/c^2}}$

Therefore, as v increases, t also increases *i.e.* the charged particle starts taking more and more time to complete the semi-circular path inside the dee. Since electric field changes the polarity of the dees after a fixed interval, the charged particle starts lagging behind the electric field and it is ultimately lost by colliding against the walls of the dees. However, this problem is overcome in the following two ways :

(*a*) As v increases, $\sqrt{1-v^2/c^2}$ decreases. Therefore, B is increased in such a manner that the factor $B\sqrt{1-v^2/c^2}$ and hence t always remains constant. Such a cyclotron, in which the strength of magnetic field is adjusted to overcome the problem due to relativistic variation in mass of the positive ion, is called ***synchrotron.***

(*b*) The frequency of revolution of charged particle inside the dees may be expressed as

$$\nu = Bq\frac{\sqrt{1-v^2/c^2}}{2\pi m_0}$$

It follows that as v increases, $\sqrt{1-v^2/c^2}$ decreases and hence ν decreases. If frequency of the electric field is adjusted to be always equal to the frequency of revolution of the charged particle, then such a cyclotron is called ***synchro-cyclotron*** or ***frequency modulated cyclotron.***

2. Cyclotron is used to accelerate heavy charged particles, such as protons. It is not suitable for accelerating electrons.

The reason is that due to small mass, the electrons gain in speed quickly and likewise the relativistic variation in mass quickly makes them out of step with the oscillating electric field.

Note. The charge on a proton is represented by the symbol e. In such a case, the symbol q may be replaced by e in the expressions obtained above.

2.06. FORCE ON A CURRENT CARRYING CONDUCTOR PLACED IN A MAGNETIC FIELD (FORCE ON A CURRENT)

Consider a straight conductor PQ of length l placed along Y-axis. Suppose that a uniform magnetic field of strength $\vec{B}$ acts along Z-axis *i.e.* perpendicular to the length of the conductor [Fig. 2.08]. Further suppose that current I flows through the conductor from its end P to Q, so that the vector $\vec{I\,l}$ (current element vector) is along OY.

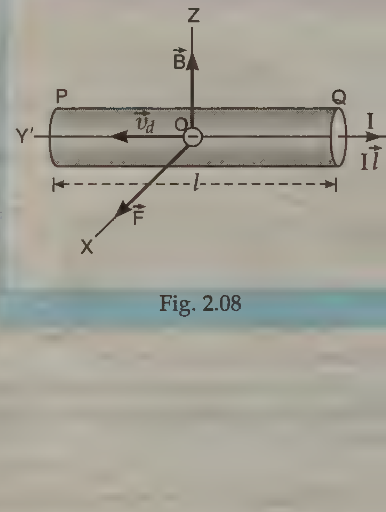

Fig. 2.08

H.A. Lorentz was the first to suggest that the electric current in metals is due to the flow of electrons. In a conductor, current flows due to drift velocity (v_d) of the electrons. If the conductor has area of cross-section A and the number of free electrons per unit volume equal to n, then the current flowing through the conductor is given by

$$I = nAev_d$$

Multiplying both sides by l, we have

$$Il = nAlev_d$$

The direction of flow of the conventional current I is opposite to that of the drift velocity of the electrons. In other words, $\vec{I\,l}$ and $\vec{v}_d$ have opposite directions and likewise the above equation may be written as

$$\vec{I\,l} = -nAle\,\vec{v}_d \qquad ...(2.23)$$

The magnetic Lorentz force on an electron having charge $-e$ and moving with velocity $\vec{v}_d$ inside the magnetic field of strength $\vec{B}$ is given by

$$\vec{f} = -e(\vec{v}_d \times \vec{B}) \qquad ...(2.24)$$

Each of the free electron inside the conductor experiences force $\vec{f}$ under the effect of magnetic field. If N is the total number of electrons in the conductor, then force on the current carrying conductor placed inside the magnetic field is given by

$$\vec{F} = N \times \vec{f} \qquad ...(2.25)$$

Now, the total number of free electrons in the conductor,

$$N = n \times \text{volume of conductor} = n\,A\,l$$

Substituting for N and $\vec{f}$ in equation (2.25), the force on the conductor,

$$\vec{F} = n\,A\,l\left(-e\,(\vec{v}_d \times \vec{B})\right) = (-n\,A\,l\,e\,\vec{v}_d) \times \vec{B}$$

Using equation (2.23), we have

$$\vec{F} = \mathrm{I}\,\vec{l} \times \vec{B} \qquad \text{...(2.26)}$$

Magnitude of force. From equation (2.26), the magnitude of the force on the urrent carrying conductor is given by

$$F = B\,I\,l \sin\theta, \qquad \text{...(2.27)}$$

here θ is the angle between the direction of magnetic field and the direction of flow f current.

(*i*) If $\theta = 0°$ or $180°$ *i.e.* $\sin\theta = 0$, then

$$F = B\,I\,l\,(0) = 0$$

Thus, if the current carrying conductor is placed ***parallel*** to the direction of agnetic field, it ***does not*** experience any force.

(*ii*) If $\theta = 90°$, then

$$F = B\,I\,l \sin 90° = B\,I\,l \qquad \textit{(maximum)}$$

In other words, a current carrying conductor experiences ***maximum*** force in a agnetic field, when it is placed ***perpendicular*** to the direction of magnetic field.

Direction of force. If $\mathrm{I}\,\vec{l}$ and $\vec{B}$ are oriented along OY and OZ respectively as hown in Fig. 2.08, then equation (2.26) tells that the force $\vec{F}\;(= \mathrm{I}\,\vec{l} \times \vec{B})$ on the onductor will act along OX.

In practice, to find the direction of force on a current carrying conductor, ***leming's left hand rule*** is used.

2.07. FLEMING'S LEFT HAND RULE

It states that *if the fore-finger, central finger and the thumb of left hand are stretched utually perpendicular to each other, such that the fore-finger points in the direction of agnetic field* ($\vec{B}$) *and the central finger in the direction of current (I), then the thumb points the direction of the force* ($\vec{F}$) *experienced by the conductor.*

The rule has been illustrated in Fig. 2.09.

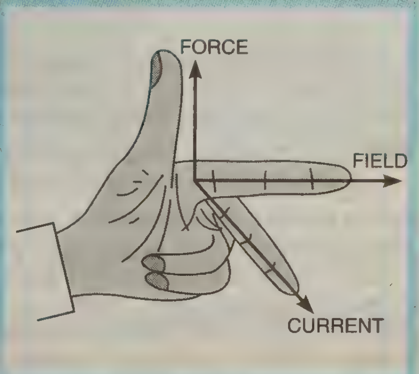

Fig. 2.09

Note. The equation (2.26) holds only *if the magnetic field is uniform over the whole ngth of the conductor.* If magnetic field is uniform over a small element of length dl nly, then force on the small element of the conductor is given by

$$d\vec{F} = \mathrm{I}\,d\vec{l} \times \vec{B} \qquad \text{...(2.28)}$$

2.08. FORCE BETWEEN TWO INFINITELY LONG PARALLEL CURRENT CARRYING CONDUCTORS

Consider two infinitely long conductors X_1Y_1 and X_2Y_2 placed parallel to each ther at a distance r apart. The currents I_1 and I_2 are flowing through the conductors $_1Y_1$ and X_2Y_2 in the same direction as shown in Fig. 2.10.

Let us find the *force experienced per unit length* by the current carrying conductor $_1Y_1$ due to the magnetic field produced by the current carrying conductor X_2Y_2.

Magnetic field at point P (on the conductor X_1Y_1) due to curernt I_2 flowing rough the infinitely long conductor X_2Y_2 is given by

$$B_2 = \frac{\mu_0}{4\pi}\cdot\frac{2I_2}{r}$$

According to the right hand thumb rule, the direction of the magnetic field B_2 point P is perpendicular to the plane of paper and in inward direction. Now, e conductor X_1Y_1 carrying current I_1 lies in the magnetic field B_2 produced by the onductor X_2Y_2. Since $F = B\,I\,l$, the force experienced by the *unit length* of the onductor X_1Y_1 due to magnetic field B_2 is given by

$$F = B_2 \times (I_1 \times 1) = \frac{\mu_0}{4\pi}\cdot\frac{2I_2}{r} \times I_1$$

or

$$F = \frac{\mu_0}{4\pi}\cdot\frac{2I_1 I_2}{r} \qquad \text{...(2.29)}$$

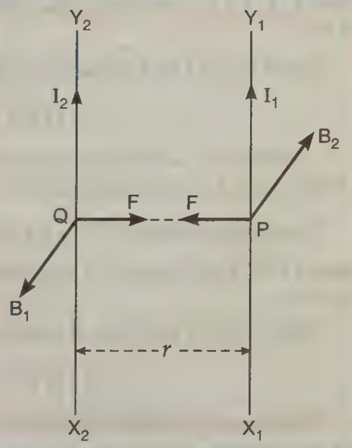

Fig. 2.10

Applying Fleming's left hand rule, it follows that the force F on the conductor X_1Y_1 acts in the plane of the paper and towards left. If we proceed in a similar manner, then it can be proved that the conductor X_2Y_2 experiences an equal force in the plane of the paper but towards right.

Therefore, the two parallel conductors carrying currents in the same direction attract each other and the magnitude of force, that each conductor exerts on the unit length of the other conductor, is given by equation (2.29).

On the other hand, it can be easily shown *that if the two parallel conductors carry currents in opposite directions, they repel each other* and the magnitude of the force experienced per unit length by one conductor due to the other is same as given by equation (2.29).

Definition of ampere. Let $I_1 = I_2 = 1$ A ; $r = 1$ m

Then, from equation (2.29), we have

$$F = \frac{10^{-7} \times 2 \times 1 \times 1}{1} = 2 \times 10^{-7} \text{ N m}^{-1}$$

Thus, *one ampere is that current, which when flowing through each of the two parallel conductors of infinite length and placed in free space at a distance of one metre from each other, produces between them a force of* 2×10^{-7} *newton per metre of their lengths.*

Note. When two infinitely long current carrying conductors are placed parallel to each other, then equation (2.29) for force experienced per unit length by one conductor due to the other has been obtained in a qualitative manner. A general expression for force can be obtained between two short parallel current carrying conductors by making use of equation (2.28) for force on a short current carrying conductor placed inside magnetic field. It can be proved that when two short conductors of lengths dl_1 and dl_2 and carrying currents I_1 and I_2 respectively are placed parallel to each other at a distance r apart, then force on one short conductor due to the other is given by

$$F = \frac{\mu_0}{4\pi} \cdot \frac{I_1 I_2 \, dl_1 \, dl_2}{r^2} \qquad \text{...(2.30)}$$

When the current flows in same direction through the two elements, they attract each other and when the two parallel conductors carry currents in opposite directions, then the current elements repel each other with equal forces.

2.09. TORQUE ON A CURRENT LOOP PLACED IN A MAGNETIC FIELD

Consider that a rectangular coil ABCD is suspended in a uniform magnetic field $\vec{B}$ acting in the plane of the paper from left to right [Fig. 2.11]. Let l be length (AB or CD) and b be breadth (AD or BC) of the coil. Suppose that the coil carries current I in the direction ABCD and the normal to the plane of the coil makes an angle θ with the direction of the magnetic field. Let $\vec{F_1}, \vec{F_2}, \vec{F_3}$ and $\vec{F_4}$ be the forces acting on the four current carrying arms DA, BC, AB and CD of the coil respectively due to the magnetic field. It follows that the force on arm AD,

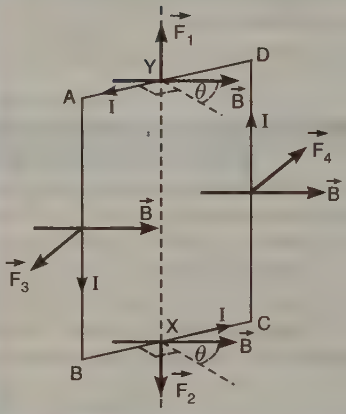

Fig.2.11

$$\vec{F_1} = I(\overrightarrow{DA}) \times \vec{B},$$

where $I(\overrightarrow{DA})$ is a vector in the direction of flow of current through the arm DA of the coil.

Since $I(\overrightarrow{DA})$ and $\vec{B}$ make angle $(90° + \theta)$, we have

$$F_1 = |I(\overrightarrow{DA})| \; |\vec{B}| \sin(90° + \theta) = (I\,b)\,B \cos\,\theta = B\,I\,b \cos\,\theta$$

The force $\vec{F_1}$ acts on arm DA in the direction of vector $I(\overrightarrow{DA}) \times \vec{B}$ *i.e.* in the plane of the coil and in upward direction.

The force on arm BC, $\vec{F_2} = I(\overrightarrow{BC}) \times \vec{B}$,

where $I(\overrightarrow{BC})$ is a vector in the direction of flow of current through the arm BC of the coil.

Since $I(\overrightarrow{BC})$ and $\vec{B}$ and make angle $(90° - \theta)$, we have

$$F_2 = |I(\overrightarrow{BC})| \; |\vec{B}| \sin(90° - \theta) = (I\,b)\,B \cos\,\theta = B\,I\,b \cos\,\theta$$

The force $\vec{F_2}$ acts in the direction of vector $I(\overrightarrow{BC}) \times \vec{B}$ *i.e.* in the plane of the coil and in downward direction.

Thus, forces $\vec{F_1}$ and $\vec{F_2}$ acting on the coil are equal in magnitude and opposite in direction. As the forces $\vec{F_1}$ and $\vec{F_2}$ have the same line of action, their resultant effect on the coil is zero.

Now, the force on arm AB, $\vec{F_3} = I(\overrightarrow{AB}) \times \vec{B}$,

where $I(\overrightarrow{AB})$ is the vector in the direction of flow of current through the arm AB of the coil.

The angle between the direction of magnetic field $\vec{B}$ and the side AB is 90°.

Therefore, $F_3 = |I(\overrightarrow{AB})|\,|\vec{B}|\sin 90° = (I\,l)\,B\,(1) = B\,I\,l$

The force $\vec{F_3}$ acts in the direction of vector $I(\overrightarrow{AB}) \times \vec{B}$ *i.e.* perpendicular to the paper and towards the reader.

Finally, the force on arm CD, $\vec{F_4} = I(\overrightarrow{CD}) \times \vec{B}$,

where $I(\overrightarrow{CD})$ is the vector in the direction of flow of current through the arm CD of the coil.

As the angle between the direction of magnetic field $\vec{B}$ and the side CD is 90°, we have

$$F_4 = |I(\overrightarrow{CD})|\,|\vec{B}|\sin 90° = (I\,l)\,B\,(1) = B\,I\,l$$

The force $\vec{F_4}$ acts in the direction of vector $I(\overrightarrow{CD}) \times \vec{B}$ *i.e.* perpendicular to the plane of the paper and away from the reader.

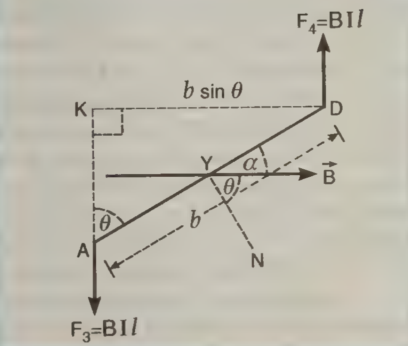

Fig. 2.12

Thus, the two forces $\vec{F_3}$ and $\vec{F_4}$ are equal in magnitude and opposite in direction. Fig. 2.12 shows the orientations of the forces $\vec{F_3}$ and $\vec{F_4}$ on the arms AB and CD, when seen from the top of the coil. As the two forces have different lines of action, they constitute a torque, whose magnitude is given by

$$\tau = \text{either force} \times KD,$$

where KD is the perpendicular distance between the forces $\vec{F_3}$ and $\vec{F_4}$.

As already said, the direction of the magnetic field $\vec{B}$ makes an angle θ with the normal (YN or Y′N′) to plane of the coil. Therefore, ∠ KAD = θ*. From right angled triangle AKD, we have

$$KD = AD \sin\theta = b \sin\theta$$

$$\therefore \quad \tau = BI\,l \times b \sin\theta$$

Since $l \times b = A$, the area of the coil ABCD, it follows that

$$\tau = B\,I\,A \sin\theta \qquad \text{...(2.31)}$$

As seen from top of the coil, the torque so produced will rotate the coil in anticlockwise direction. In vector notation,

$$\vec{\tau} = (I\,\vec{A}) \times \vec{B}, \qquad \text{...(2.32)}$$

where $\vec{A}$ is the vector representing the area of the coil and is directed along YN (or Y′N′), normal to the plane of the coil.

Key point

Torque on a planar current loop depends upon current, strength of magnetic field and area of the loop. It is independent of the shape of the loop.

Now, $I\,\vec{A} = \vec{M}$, the magnetic dipole moment of the current loop. Therefore,

$$\vec{\tau} = \vec{M} \times \vec{B} \qquad \text{...(2.33)}$$

Note. 1. If the coil has n turns, then

$$\tau = n\,B\,I\,A \sin\theta \qquad \text{...(2.34)}$$

2. If the direction of the magnetic field makes an angle α with the plane of the coil as shown in Fig. 2.12, then

$$\theta + \alpha = 90° \quad \text{or} \quad \theta = 90° - \alpha \quad \text{or} \quad \sin\theta = \sin(90° - \alpha) = \cos\alpha$$

Then, equation (2.34) becomes

$$\tau = n\,B\,I\,A \cos\alpha \qquad \text{...(2.35)}$$

3. The above expressions for the torque on the coil has been obtained for a rectangular loop. In fact, these expressions hold for a planar current loop of any shape.†

---

*Since the angle between two lines is same as the angle between their perpendiculars, it can be easily shown that ∠ KAD = θ.

†For detailed explanation, refer to S.A.Q. 2.27.

2.10. MOVING COIL GALVANOMETER

The moving coil galvanometer was first devised by Kelvin and later on modified by D' Arsonaval. It is also known as ***American type galvanometer.***

It is a device used to detect small current flowing in an electric circuit. With suitable modifications, a moving coil galvanometer can be used to measure current and potential difference.

Principle. *When a current carrying coil is placed in a magnetic field, it experiences a torque.*

Construction. It consists of a coil ABCD suspended between the poles of a permanent magnet NS as shown in Fig. 2.13. The coil is wound on a non-metallic frame and has a central soft iron core. The coil is suspended from the torsion head with a phosphor bronze wire. The other end of the coil is attached to a hair spring. A small concave mirror M is attached to the suspension wire. The whole arrangement is enclosed in a non-magnetic case to avoid disturbance due to air. The galvanometer can be levelled with the help of levelling screws, so that the coil can rotate freely without touching the iron core or the poles of the magnet.

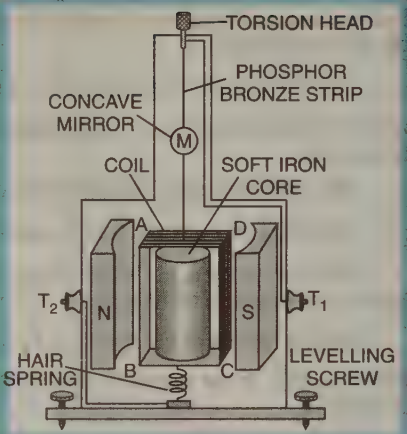

Fig. 2.13

To connect the galvanometer in the circuit, the binding screws T_1 and T_2 are provided at the back of the case of the galvanometer.

Theory. Suppose that the rectangular coil ABCD having n turns is of length l (= AB or CD) and breadth b (= AD or BC). Let B be the strength of the magnetic field due to the magnet NS. Initially *i.e.* (before passing the current through the galvanometer), the plane of the coil is parallel to the magnetic field. When current is passed through the coil, forces act on all the arms of the coil. The forces on arms DA and BC being equal and opposite*, cancel the effect of each other. If current is passed in the direction of ABCD, then

force on arm AB, $F = n\,B\,I\,l$ (normally outwards)

and force on arm CD, $F = n\,B\,I\,l$ (normally inwards)

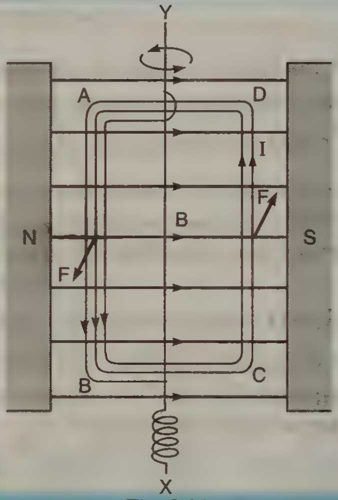

Fig. 2.14

The two forces are equal, opposite, parallel and act at different points as shown in Fig. 2.14. Hence, the two forces constitute a torque. As the coil rotates under the effect of the torque, the suspension wire gets twisted and a restoring torque is developed in the suspension wire. The coil will rotate, till *the deflecting torque acting on the coil due to flow of current is balanced by the restoring torque developed in the suspension wire due to twisting.* Therefore, in equilibrium,

deflecting torque = restoring torque (in magnitude)

Suppose the coil comes to rest after rotating through an angle α. In this position, the plane of the coil makes angle α with the direction of the field as shown in Fig. 2.15. The perpendicular distance between the forces acting on arms AB and CD is given by

$$DK = AD\cos\alpha = b\cos\alpha$$

Therefore, deflecting torque acting on coil = either force × DK = $n\,B\,I\,l \times b\cos\alpha$

$$= n\,B\,I\,A\cos\alpha, \qquad ...(2.36)$$

where $A = l \times b$ is the area of the coil. If k is the restoring torque per unit twist for the material of the suspension wire, then

$$\text{restoring torque} = k\,\alpha$$

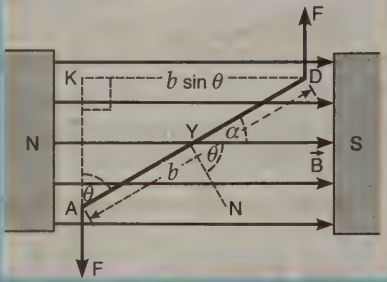

Fig. 2.15

Since in equilibrium, the restoring torque is just equal and opposite to the deflecting torque,

$$n\,B\,I\,A\cos\alpha = k\,\alpha$$

or
$$I = \frac{k}{n\,B\,A}\cdot\frac{\alpha}{\cos\alpha}$$

Since the factor $\dfrac{k}{n\,B\,A}$ is constant for the given galvanometer,

$$I \propto \frac{\alpha}{\cos\alpha}$$

As the deflection (α) produced is not directly proportional to the current (I) passing through the galvanometer, a linear scale cannot be used for measuring the current. In order that deflection produced in the coil of the galvanometer may be directly proportional to the current passed, the poles of the magnet are made concave so as to produce ***radial magnetic field.*** In such a field, the plane of the coil is parallel to the magnetic lines of force in all positions of the coil [Fig. 2.16] and hence

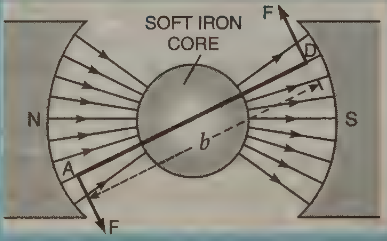

Fig. 2.16

---

* For details refer to section 2.09.

rpendicular distance between the forces on the two arms of the coil is always equal b, the breadth of the coil. Therefore, in case of radial magnetic field,

deflecting torque $= n\,B\,I\,l \times b = n\,B\,I\,A$

In equilibrium, $n\,B\,I\,A = k\,\alpha$

or $$I = \frac{k}{n\,B\,A}\,\alpha \qquad ...(2.37)$$

or $$I = G\,\alpha, \qquad ...(2.38)$$

here $G = \dfrac{k}{n\,B\,A}$ is constant for a galvanometer and is called ***galvanometer nstant.***

Hence, $I \propto \alpha$

deflection produced is directly proportional to the current passed through the lvanometer. Such a galvanometer will have a linear scale.

Sensitivity. *A galvanometer is said to be sensitive, if it gives a large deflection, even nen a small current is passed through it or a small voltage is applied across its coil.*

Current sensitivity. *It is defined as the deflection produced in the galvanometer on ssing unit current through its coil.* Therefore, if α is the deflection produced on passing rrent I, then

$$\text{current sensitivity } \frac{\alpha}{I} = \frac{n\,B\,A}{k} \qquad ...(2.39)$$

Voltage sensitivity. *It is defined as the deflection produced in the galvanometer, hen a unit voltage is applied across its coil.* Therefore, if α is the deflection produced n applying voltage V, then

$$\text{voltage sensitivity} = \frac{\alpha}{V}$$

If R is the resistance of coil and I is the current that passes through coil on pplying voltage V, then

$$V = I\,R$$

Therefore, voltage sensitivity, $$\frac{\alpha}{V} = \frac{\alpha}{I\,R} = \frac{n\,B\,A}{k\,R} \qquad ...(2.40)$$

It follows that a galvanometer will be highly sensitive, if

(*i*) *n is large ;* (*ii*) *B is large ;* (*iii*) *A is large ;* (*iv*) *k is small* and (*v*) *R is small.*

However, n and A cannot be increased beyond a certain limit, as otherwise the ze of the galvanometer and its resistance will become large. Therefore, B is made s large as possible and k is made as small as possible. To increase B, a very strong ermanent magnet is used. To decrease k, the suspension wire is made of phosphor ronze ; as for this material, k is very small. The value of k further decreases, if the vire is hammered in to a flat strip. In very sensitive galvanometers, quartz fibre is sed for suspension of the coil ; as for quartz, k is still smaller.

2.11. AMMETER

An ammeter is an instrument used for measuring current in the electrical circuits.

A galvanometer is a low resistance instrument and as such it cannot be used o measure current in a circuit. It is because, when even a small current is passed hrough the galvanometer, it produces full scale deflection. If a large current is assed, the galvanometer may be damaged because of the following two reasons :

(*i*) The large current will cause the coil of the galvanometer to deflect through large angle and the pointer of the galvanometer, in an attempt to go out of scale, nay break.

(*ii*) The large current on its passage through the coil of the galvanometer will roduce a large amount of heat. The excessive heating may also damage the alvanometer.

However, when a galvanometer is converted into ammeter, it can measure urrents without causing any damage to it.

To convert a galvanometer into an ammeter. Suppose that the galvanometer s to be converted into an ammeter of range 0 to I ampere. Further, suppose that he galvanometer gives full scale deflection, when current I_g (usually very small as compared to I) is passed through it. In order to convert the galvanometer into an ammeter of the required range, a small resistance S is connected in parallel to he coil of the galvanometer. Its value is so adjusted that when current I is passed, only the part I_g passes through the coil of the galvanometer and the remaining part $(I - I_g)$ flows through the resistance S [Fig. 2.17].

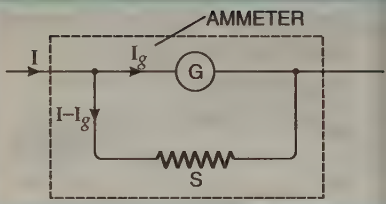

Fig. 2.17

Let G be the resistance of the coil of the galvanometer. Since the coil of the galvanometer and the shunt are connected across the same two points,

potential difference across shunt = potential difference across the coil

i.e. $$(I - I_g) \times S = I_g \times G$$

or $$S = \frac{I_g}{I - I_g} G \qquad ...(2.41)$$

Knowing the values of I_g, I and G, the value of S can be calculated. By connecting shunt of this value, the given galvanometer will work as an ammeter of the given range (0 to I ampere).

Note. 1. The parallel combination of galvanometer and the shunt constitutes the ammeter.

2. The ammeter so obtained has the resistance R_A, which is given by

$$\frac{1}{R_A} = \frac{1}{G} + \frac{1}{S} = \frac{S + G}{GS}$$

or $$R_A = \frac{GS}{S + G} \qquad ...(2.42)$$

In practice, G is large as compared to S. Therefore, practically $R_A \approx S$. Thus, resistance of the ammeter formed will be very low as compared to that of galvanometer. However, an ideal ammeter has ***zero resistance.***

3. As ammeter is an instrument of low resistance, it is always connected in series with the circuit. Because of the low resistance of the ammeter, on its introduction in the circuit, the resistance of the circuit practically remains unchanged and consequently the current in the circuit also remains unaffected.

Key point

1. The resistance of an ammeter is always much smaller than the resistance of the galvanomter, from which it is obtained.

2. The range of an ammeter can be increased but it cannot be decreased.

2.12. VOLTMETER

A voltmeter is an instrument used for measuring potential difference across the two ends of a conductor carrying current.

A galvanometer cannot be used to measure potential difference across a conductor in the circuit. It is because, when a galvanometer is connected in parallel to the conductor in order to measure potential difference across it ; due to low resistance of the galvanometer, a large part of the current will flow through it. As a result, current flowing through the conductor and hence potential difference across it will decrease on connecting galvanometer across it. Therefore, a galvanometer is converted into a voltmeter, so that it can measure potential difference across a conductor without causing any change (decrease) in the current flowing through it.

To convert a galvanometer into a voltmeter. Suppose the galvanometer is to be converted into a voltmeter of range 0 to V volt. Further, suppose that the galvanometer gives full scale deflection, when current I_g is passed through it. The resistance R is connected in series to the galvanometer so as to convert it into the required voltmeter [Fig. 2.18]. For this, the value of R is adjusted so that when a battery of V volt (maximum value of potential difference to be measured) is connected across the series combination of galvanometer and resistance R, the galvanometer gives full scale deflection *i.e.* current equal to I_g flows through it. If G is the resistance of the galvanometer, then

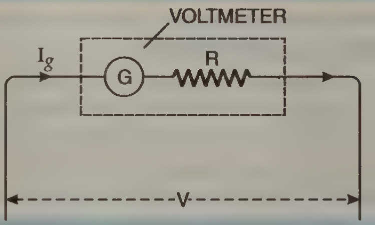

Fig. 2.18

$$I_g = \frac{V}{G + R}$$

or $$R = \frac{V}{I_g} - G \qquad ...(2.43)$$

Knowing V, I_g and G, the value of the R can be found. When the resistance of this value is connected in series to the galvanometer, it will work as a voltmeter of range 0 to V volt.

Note. 1. The series combination of galvanometer and the resistance R constitutes the voltmeter.

2. The voltmeter so obtained has resistance,

$$R_V = G + R \qquad ...(2.44)$$

In practice, it is found that R_V is very large as compared to the value of G. Hence, voltmeter is a high resistance instrument. An ideal voltmeter should possess *ıfinite resistance.*

3. Because of the high resistance of the voltmeter, it is connected in parallel to ıe conductor across which potential difference is to be measured. It is because, as ıe voltmeter will not practically draw any current due to its high resistance, the ırrent through the conductor will not change.

Key point

1. The resistance of a voltmeter is very large as compared to the resistance of the galvanometer, from which it is obtained.
2. The range of a voltmeter can be both increased and decreased.

ype A. On Motion of Charged Particle inside Electric field

Problem 2.01. A proton is initially travelling with orizontal velocity $v_x = 5{\cdot}0 \times 10^8$ cm s^{-1}. Calculate the ansverse deflection in travelling horizontal distance, = 10 cm in electric field of $E_y = 200$ volt cm^{-1}. Mass of proon, $m = 1{\cdot}6 \times 10^{-24}$ g ; charge on electron, $e = 1{\cdot}6 \times 10^{-19}$ C.

Sol. Here, $m = 1{\cdot}6 \times 10^{-24}\text{ g} = 1{\cdot}6 \times 10^{-27}\text{ kg}$;

$$e = 1{\cdot}6 \times 10^{-19}\text{ C}$$

Strength of electric field along Y-axis,

$$E_y = 200\text{ V cm}^{-1} = 200\text{ V} \times \left(\frac{1}{100}\text{ m}\right)^{-1} = 2 \times 10^4\text{ V m}^{-1}$$

Distance travelled along X-axis, $x = 10\text{ cm} = 0{\cdot}1\text{ m}$

Velocity along X-axis,

$$v_x = 5{\cdot}0 \times 10^8\text{ cm s}^{-1} = 5{\cdot}0 \times 10^6\text{ m s}^{-1}$$

If t is the time for which electron remains inside the ectric field, then

$$t = \frac{x}{v_x} = \frac{0{\cdot}1}{5{\cdot}0 \times 10^6} = 2 \times 10^{-8}\text{ s}$$

Force on proton along Y-axis,

$$F_y = e\,E_y = 1{\cdot}6 \times 10^{-19} \times 2 \times 10^4\text{ N}$$

Therefore, acceleration of proton along Y-axis,

$$a = \frac{F_y}{m} = \frac{1{\cdot}6 \times 10^{-19} \times 2 \times 10^4}{1{\cdot}6 \times 10^{-27}} = 2 \times 10^{12}\text{ m s}^{-2}$$

Initial velocity along Y-axis, $u = 0$;

time for which electric field acts, $t = 2 \times 10^{-8}$ s

Therefore, displacement along Y-axis,

$$y = u\,t + \frac{1}{2}a\,t^2$$

$$= (0) \times 2 \times 10^{-8} + \frac{1}{2} \times 2 \times 10^{12} \times (2 \times 10^{-8})^2$$

$$= 4 \times 10^{-4}\text{ m} = \mathbf{0{\cdot}4\text{ mm}}$$

ype B. On Force on a charge moving in magnetic field

Problem 2.02. Copper has $8{\cdot}0 \times 10^{28}$ conduction ectrons per metre^3. A copper wire of length 1 m and crossectional area $8{\cdot}0 \times 10^{-6}$ m^2 carrying a current and lying at ght angle to a magnetic field of strength 5×10^{-3} T periences a force of $8{\cdot}0 \times 10^{-2}$ N. Calculate the drift velocity f free electrons in the wire. (*C.B.S.E. Sample Q. Paper*)

Sol. In a copper wire of length l, area of cross-section A nd having number of free electrons per unit volume equal n, the total charge in the wire in the form of free electrons,

q = volume of wire × number of electrons per unit volume × charge on electron

$$= (A\,l) \times n \times e = n\,A\,l\,e$$

If v_d is drift velocity of the electron, then force on the opper wire,

$$F = B\,q\,v_d \qquad (\text{angle between } \vec{B} \text{ and } \vec{v}_d \text{ is } 90°)$$

or $$v_d = \frac{F}{B\,q} = \frac{F}{B\,n\,A\,l\,e}$$

Here, $n = 8{\cdot}0 \times 10^{28}\text{ m}^{-2}$; $l = 1$ m ; $A = 8{\cdot}0 \times 10^{-6}\text{ m}^2$;

$B = 5 \times 10^{-3}$ T ; $F = 8{\cdot}0 \times 10^{-2}$ N ;

Also, $e = 1{\cdot}6 \times 10^{-9}$ C

$$\therefore\ v_d = \frac{8{\cdot}0 \times 10^{-2}}{5 \times 10^{-3} \times 8{\cdot}0 \times 10^{28} \times 8{\cdot}0 \times 10^{-6} \times 1 \times 1{\cdot}6 \times 10^{-19}}$$

$$= \mathbf{1{\cdot}5625 \times 10^{-4}\ m\ s^{-1}}$$

Problem 2.03. An electron is moving northwards with a velocity 10^7 m s^{-1} in a magnetic field of 3 T directed eastwards. Calculate the instantaneous force on the electron. Given that charge on electron = $1{\cdot}6 \times 10^{-19}$ C.

Sol. Here, $q = 1{\cdot}6 \times 0^{-19}$ C ; $v = 10^7$ m s^{-1} ; B = 3 T

As electron is moving northwards and the magnetic field is east-wards [Fig. 2.19], the angle between $\vec{v}$ and $\vec{B}$ is 90°.

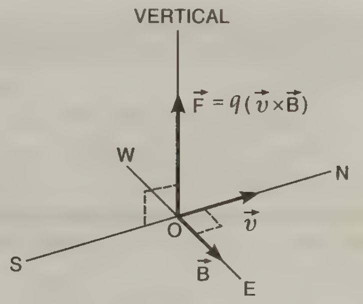

Fig. 2.19

Now, $$F = q\,v\,B \sin 90°$$

$$= 1{\cdot}6 \times 10^{-19} \times 10^7 \times 3 \times 1$$

$$= \mathbf{4{\cdot}8 \times 10^{-12}\ N}$$

Since the charge on electron is negative, force on electron,

$$\vec{F} = -q(\vec{v} \times \vec{B})$$

The direction of force on electron will be that of vector $-q(\vec{v} \times \vec{B})$ *i.e.* along vertically upwards [Fig. 2.19].

Problem 2.04. A long straight wire carries a current of 2 A. An electron travels with a velocity of 4×10^4 m s^{-1} parallel to the wire at a distance of 0·1 m from it and in a direction opposite to the current. What force does the magnetic field of current exert on the moving electron ? Given, $\mu_0 = 4\,\pi \times 10^{-7}$ T A^{-1}m and charge on electron, $q = 1{\cdot}6 \times 10^{-19}$ C.

Sol. Here, I = 2 A ; $\mu_0 = 4\,\pi \times 10^{-7}$ T A^{-1} m

Distance of the observation point from the conductor,

$$a = 0{\cdot}1\text{m}$$

Magnetic field at the observation point,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2I}{a} = \frac{10^{-7} \times 2 \times 2}{0 \cdot 1} = 4 \times 10^{-6} \text{ tesla}$$

The magnetic field acts along normal to the plane, in which the wire and the observation point lies. As the electron moves in a direction parallel to wire and opposite to the current, the angle between $\vec{v}$ and $\vec{B}$ is 90°. Therefore,

force of element, $F = B\,q\,v$

Here $q = 1{\cdot}6 \times 10^{-19}$ C and $v = 4 \times 10^4$ m s^{-1}

$\therefore \quad F = 4 \times 10^{-6} \times 1{\cdot}6 \times 10^{-19} \times 4 \times 10^4$

$= \mathbf{2{\cdot}56 \times 10^{-20}}$ **N**

Problem 2.05. A long straight wire AB carries a current of 4 A. A proton P travels at 4 × 10^6 m s^{-1} parallel to the wire, 0·2 m from it and in a direction opposite to the current as shown in Fig. 2.20. Calculate the force which the magnetic field of current exerts on the proton. Also specify the direction of the force. *(C.B.S.E. 2002)*

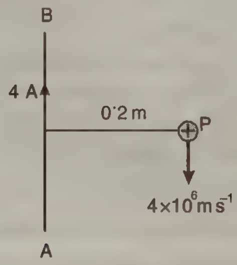

Fig. 2.20

Sol. Here, $I = 4$ A, $a = 0{\cdot}2$ m and $v = 4 \times 10^6$ m s^{-1}

Magnetic field due to a current carrying straight conductor is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2I}{a} = \frac{10^{-7} \times 2 \times 4}{0 \cdot 2}$$

$= 4 \times 10^{-6}$ T

According to right hand thumb rule, the magnetic field will be directed perpendicular to the plane of paper and in inward direction [Fig. 2.21].

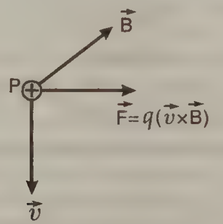

Fig. 2.21

Since proton is moving parallel to the conductor, the magnetic field produced by the current carrying straight wire is perpendicular to the direction of motion of the proton. If q is charge on proton and v is its velocity, then force on the proton due to magnetic field,

$$F = B\,q\,v = 4 \times 10^{-6} \times 1{\cdot}6 \times 10^{-19} \times 4 \times 10^6$$

$= \mathbf{2{\cdot}56 \times 10^{-18}}$ **N**

The direction of force on the proton is given by

$$\vec{F} = q(\vec{v} \times \vec{B})$$

i.e. force on the proton acts **parallel to horizontal towards right.**

Type C. On Motion of a charge inside Magnetic fiel

Problem 2.06. An electron is projected with a velocity of 10^5 m s^{-1} at right angles to a magnetic field of 0·019 G. Calculate the radius of the circular path described by the electron, if $e = 1{\cdot}6 \times 10^{-19}$ C, $m = 9{\cdot}1 \times 10^{-31}$ kg.

(C.B.S.E. Sample Q. Paper

Sol. Here, $v = 10^5$ m s^{-1} ; $e = 1{\cdot}6 \times 10^{-19}$ C ;

$m = 9{\cdot}1 \times 10^{-31}$ kg ;

$B = 0 \cdot 019$ G $= 0 \cdot 019 \times 10^{-4}$ T

Now, $\quad B\,e\,v = \dfrac{m\,v^2}{r}$

or $\quad r = \dfrac{m\,v}{B\,e} = \dfrac{9 \cdot 1 \times 10^{-31} \times 10^5}{0 \cdot 019 \times 10^{-4} \times 1 \cdot 6 \times 10^{-19}} = \mathbf{0 \cdot 299\ m}$

Problem 2.07. Electron (with a charge of 1·6 × 11^{-19} C on each) moving at right angles to the uniform magnetic fiel completes a circular orbit in 10^{-6} s. Calculate the value o magnetic field. Given, mass of electron = 9 × 10^{-31} kg.

Sol. Here, $e = 1{\cdot}6 \times 10^{-19}$ C ; $m = 9 \times 10^{-31}$ kg ; $T = 10^{-6}$

Now, $\quad \dfrac{m\,v^2}{r} = B\,e\,v \quad$ or $\quad v = \dfrac{B\,e\,r}{m}$

Therefore, period of revolution,

$$T = \frac{2\pi r}{v} = \frac{2\pi r}{B\,e\,r/m} = \frac{2\pi m}{B\,e}$$

$$\therefore B = \frac{2\pi m}{e\,T} = \frac{2\pi \times 9 \times 10^{-31}}{1 \cdot 6 \times 10^{-19} \times 10^{-6}} = \mathbf{3 \cdot 534 \times 10^{-5}\ T}$$

Problem 2.08. A proton and an alpha particle having the same kinetic energy are allowed to pass through uniform magnetic field perpendicular to their direction o motion. Compare the radii of the paths of proton and alpha particle. *(C.B.S.E. 1996*

Sol. Let q, m and v be the charge, mass and velocity o proton and Q, M and V be the respective values for alpha particle. Obviously,

$$Q = 2\,q \text{ and } M = 4\,m$$

Let r and R be the radii of circular paths followed by proton and alpha particle, while passing through the magnetic field of strength B.

Then, for proton : $\dfrac{m\,v^2}{r} = B\,q\,v$

or $\quad r = \dfrac{m\,v}{B\,q} \quad$ ...(*i*)

Similarly, for alpha particle : $R = \dfrac{M\,V}{B\,Q} = \dfrac{(4\,m)\,V}{B\,(2\,q)}$

or $\quad R = \dfrac{2\,m\,V}{B\,q} \quad$ ...(*ii*)

Dividing equation (*i*) by (*ii*), we have

$$\frac{r}{R} = \frac{m\,v}{B\,q} \times \frac{B\,q}{2\,m\,V} = \frac{1}{2}\left(\frac{v}{V}\right) \quad \text{...}(iii)$$

Since the proton and alpha particle have the same kinetic energy,

$$\frac{1}{2}\,m\,v^2 = \frac{1}{2}\,M\,V^2$$

or $\quad \dfrac{v}{V} = \sqrt{\dfrac{M}{m}} = \sqrt{\dfrac{4\,m}{m}} = 2 \quad$ ...(*iv*)

From equations (*iii*) and (*iv*), we have

$$\frac{r}{R} = \frac{1}{2} \times 2 = 1$$

ype D. On Cyclotron

Problem 2.09. A cyclotron's oscillator frequency is MHz. What should be the operating magnetic field for celerating protons? If the radius of its 'dees' is 60 cm, what the kinetic energy of the proton beam produced by the celerator ? Given, $e = 1{\cdot}60 \times 10^{-19}$ C, $m = 1{\cdot}67 \times 10^{-27}$ kg. press your answer in units of MeV.

Given, 1 MeV = $1{\cdot}6 \times 10^{-13}$ J. *(Text Problem)*

Sol. Here, $m = 1{\cdot}67 \times 10^{-27}$ kg ; $e = 1{\cdot}60 \times 10^{-19}$ C ;

$$\nu = 10 \text{ MHz} = 10^7 \text{ Hz} ; R = 60 \text{ cm} = 0{\cdot}6 \text{ m}$$

Now, $$\nu = \frac{1}{T} = \frac{Be}{2\pi m}$$

or $$B = \frac{2\pi m \nu}{e} = \frac{2\pi \times 1{\cdot}67 \times 10^{-27} \times 10^7}{1{\cdot}60 \times 10^{-19}}$$

$$= 0{\cdot}656 \text{ T}$$

Now, $$E_{max} = \frac{B^2 e^2 R^2}{2m}$$

$$= \frac{(0{\cdot}656)^2 \times (1{\cdot}60 \times 10^{-19})^2 (0{\cdot}6)^2}{2 \times 1{\cdot}67 \times 10^{-27}}$$

$$= 11{\cdot}874 \times 10^{-13} \text{ J}$$

$$= \frac{11{\cdot}874 \times 10^{-13}}{1{\cdot}6 \times 10^{-13}} = 7{\cdot}421 \text{ MeV}$$

pe E. On force on a current carrying conductor

Problem 2.10. A horizontal wire 0·1 m long carries a rrent of 5 A . Find the magnitude and direction of the gnetic field, which can support the weight of the wire. sume wire to be of mass 3×10^{-3} kg m^{-1}.

Sol. Here, $I = 5$ A ; $l = 0{\cdot}1$ m ;

mass per unit length of the wire $= 3 \times 10^{-3}$ kg m^{-1}

Therefore, weight of the wire,

$$mg = 3 \times 10^{-3} \times 0{\cdot}1 \times 9{\cdot}8 = 2{\cdot}94 \times 10^{-3} \text{ N}$$

Let B be the strength of the magnetic field applied. Then,

$$F = BIl = B \times 5 \times 0{\cdot}1 = 0{\cdot}5 \text{ B}$$

In equilibrium, $F = mg$

$\therefore$ $0{\cdot}5 \text{ B} = 2{\cdot}94 \times 10^{-3}$

or $$B = \frac{2{\cdot}94 \times 10^{-3}}{0{\cdot}5} = 5{\cdot}88 \times 10^{-3} \text{ tesla}$$

pe F. On Force between two long straight current carrying conductors

Problem 2.11. Calculate the force per unit length on ong straight wire carrying current of 4 A due to a allel wire carrying 6 A current. Distance between the es = 3 cm. *(H.S.S.C.E. 1998 ; C.B.S.E. 1991)*

Sol. Here, $I_1 = 4$ A ; $I_2 = 6$ A ; $r = 3$ cm $= 0{\cdot}03$ m

Now, $$F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r} = \frac{10^{-7} \times 2 \times 4 \times 6}{0{\cdot}03}$$

$$= 1{\cdot}6 \times 10^{-4} \text{ N m}^{-1}$$

Problem 2.12. Two long parallel wires are 0·4 m apart air and carry currents of 5 A and 12 A respectively. culate the force on each metre of the wire, if the rents are in (*i*) the same direction and (*ii*) in the osite direction. Given, $\mu_0 = 4\pi \times 10^{-7}$ T A^{-1} m.

Sol. Here, $I_1 = 5$ A ; $I_2 = 12$ A ; $r = 0{\cdot}4$ m ;

$$\mu_0 = 4\pi \times 10^{-7} \text{ T A}^{-1} \text{ m}$$

(i) When currents flow in the same direction. The conductors will *attract* each other. The force on one metre of a wire due to the whole length of the other wire,

$$F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r} = \frac{10^{-7} \times 2 \times 2 \times 5 \times 12}{0{\cdot}4}$$

$$= 3 \times 10^{-5} \text{ N m}^{-1}$$

(ii) When currents flow in the opposite directions. The two conductors will *repel* each other, In this case,

$$F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r} = 3 \times 10^{-5} \text{ N m}^{-1}$$

Problem 2.13. The wires which connect the battery of an automobile to its starting motor carry a current of 300 A (for a short time). What is the force per unit length between the wires, if they are 70 cm long and 1·5 cm apart ? Is the force attractive or repulsive ?

(H.S.S.C.E. 2001 ; P.S.S.C.E. 1995 ; Text Problem)

Sol. Force on a unit length of a current carrying conductor due to another *infinitely long* parallel current carrying conductor is given by

$$F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r}$$

Here $I_1 = I_2 = 300$ A ; $r = 1{\cdot}5$ cm $= 1{\cdot}5 \times 10^{-2}$ m

$\therefore$ $$F = \frac{10^{-7} \times 2 \times 300 \times 300}{1{\cdot}5 \times 10^{-2}} = 1{\cdot}2 \text{ N m}^{-1}$$

$$\left(\because \frac{\mu_0}{4\pi} = 10^{-7} \text{ T A m}^{-1} \right)$$

In the two wires connecting the battery to the starting motor, the current will flow in opposite directions. Hence, the force is **repulsive.**

Type G. On Torque on a current loop

Problem 2.14. Calculate the torque on a 100 turn rectangular coil of length 40 cm and breadth 20 cm, carrying a current of 10 A, when placed making an angle of 60° with a magnetic field of 5 T.

Sol. Here, $I = 10$ A ; $n = 100$;

$A = 40 \text{ cm} \times 20 \text{ cm} = 800 \text{ cm}^2 = 8 \times 10^{-2} \text{ m}^2$; $B = 5$ T ;

$\alpha = 60°$ (angle between field and plane of coil)

Now, $\tau = nBIA\cos\alpha = 100 \times 5 \times 10 \times 8 \times 10^{-2} \times \cos 60°$

$= \mathbf{200 \text{ N m}}$

Problem 2.15. (*a*) A circular coil of 30 turns and radius 8·0 cm carrying a current of 6·0 A is suspended vertically in a uniform horizontal magnetic field of magnitude 1·0 T. The field lines make an angle of 60° with the normal to the coil. Calculate the magnitude of the counter torque, that must be applied to prevent the coil from turning.

(*b*) Would your answer change, if the circular coil in (*a*) were replaced by a planar coil of some irregular shape that encloses the same area ? (All other particulars are also unaltered). *(Text Problem)*

Sol. Here, $n = 30$; $I = 6{\cdot}0$ A ; $B = 1{\cdot}0$ T ;

$\theta = 60°$ (angle between field and normal to coil) ;

radius of coil, $r = 8{\cdot}0 \text{ cm} = 8{\cdot}0 \times 10^{-2}$ m

Therefore, area of coil,

$$A = \pi r^2 = \pi \times (8{\cdot}0 \times 10^{-2})^2 = 2{\cdot}01 \times 10^{-2} \text{ m}^2$$

(*a*) Now, torque acting on the current carrying coil due to magnetic field,

$$\tau = n\,\mathrm{B\,I\,A}\sin\theta = 30 \times 1{\cdot}0 \times 6{\cdot}0 \times 2{\cdot}01 \times 10^{-2} \sin 60°$$
$$= 30 \times 1{\cdot}0 \times 6{\cdot}0 \times 2{\cdot}01 \times 10^{-2} \times 0{\cdot}866 = \mathbf{3{\cdot}133\ N\ m}$$

To prevent the coil from rotating, a torque equal and opposite to $\tau = (= 3{\cdot}133\ \mathrm{N\ m})$ has to be applied.

(*b*) Since torque on a planar loop is independent of its shape (provided area is same), the torque will remain **unchanged.**

Problem 2.16. Given a uniform magnetic field of 100 G in an east to west direction and a 44 cm long wire with a current carrying capacity of at most 10 A. What is the shape and orientation of the loop made of this wire, which yields maximum turning effect on the loop ? What is the magnitude of the maximum torque ? (*Text Problem*)

Sol. Here, $\mathrm{B} = 100\ \mathrm{G} = 100 \times 10^{-4}\ \mathrm{T}$; $\mathrm{I} = 10\ \mathrm{A}$

The torque on a planar loop will be maximum, if it has maximum area. For a given perimeter, a circle encloses maximum area. If 44 cm long wire is bent into a circular loop of radius *r*, then

$$2\pi r = 44$$

or $$r = \frac{44}{2\pi} = \frac{44 \times 7}{2 \times 22} = 7\ \mathrm{cm}$$

Area of loop,

$$\mathrm{A} = \pi r^2 = \pi \times 7^2 = \frac{22}{7} \times 49 = 154\ \mathrm{cm}^2$$
$$= 154 \times 10^{-4}\ \mathrm{m}^2$$

Now, $\tau = \mathrm{B\,I\,A}\sin\theta$

For maximum turning effect, $\theta = 90°$ *i.e.* $\sin\theta = 1$.

$$\therefore \quad \tau_{max} = \mathrm{B\,I\,A} = 100 \times 10^{-4} \times 10 \times 154 \times 10^{-4}$$
$$= \mathbf{1{\cdot}54 \times 10^{-3}\ N\ m}$$

Problem 2.17. A circular coil of 20 turns and radius 10 cm is placed in a uniform magnetic field of 0·10 T normal to the plane of the coil. If the current in the coil is 5·0 A, what is the (*a*) total torque on the coil, (*b*) total force on the coil, (*c*) average force on each electron in the coil due to the magnetic field. The coil is made of copper wire of cross-sectional area $10^{-5}\ \mathrm{m}^2$ and the free electron density in copper is given to be about $10^{29}\ \mathrm{m}^{-3}$.

Sol. Here, $n = 20$; $r = 10\ \mathrm{cm} = 10 \times 10^{-2}\ \mathrm{m}$;
$\mathrm{B} = 0{\cdot}10\ \mathrm{T}$; $\mathrm{I} = 5{\cdot}0\ \mathrm{A}$;
angle between field and normal to the coil, $\theta = 0°$
Area of the coil, $\mathrm{A} = \pi r^2 = \pi \times (10 \times 10^{-2})^2 = \pi \times 10^{-2}\ \mathrm{m}^2$

(*a*) $\tau = n\,\mathrm{B\,I\,A}\sin\theta = 20 \times 0{\cdot}10 \times 5{\cdot}0 \times \pi \times 10^{-2} \sin 0°$
$= 20 \times 0{\cdot}10 \times 5{\cdot}0 \times \pi \times 10^{-2} \times 0 = 0$

(*b*) Net force on a planar current loop in a magnetic field is always zero.

(*c*) Force on one electron $= \mathrm{B}\,e\,v_d = \mathrm{B}\,e\left(\dfrac{\mathrm{I}}{n\,e\,\mathrm{A}}\right) = \dfrac{\mathrm{BI}}{n\,\mathrm{A}}$

Here, $n = 10^{29}\ \mathrm{m}^{-3}$; $\mathrm{A} = 10^{-5}\ \mathrm{m}^2$

Therefore, force on one electron

$$= \frac{0{\cdot}10 \times 5{\cdot}0}{10^{29} \times 10^{-5}} = 5 \times 10^{-25}\ \mathrm{N}$$

Type H. On Moving coil galvanometer

Problem 2.18. A rectangular coil of area $5{\cdot}0 \times 10^{-4}\ \mathrm{m}^2$ and 60 turns is pivoted about one of its vertical sides. The coil is in a radial horizontal field of 90 G ('radial' here means the field lines are in the plane of the coil for ar orientation). What is the torsional constant of the ha springs connected to the coil, if a current of 0·20 m produces an angular deflection of 18° ? (*Text Probler*

Sol. Here, $\mathrm{A} = 5{\cdot}0 \times 10^{-4}\ \mathrm{m}^2$; $n = 60$; $\alpha = 18°$;
$\mathrm{B} = 90\ \mathrm{G} = 90 \times 10^{-4}\ \mathrm{T}$;
$\mathrm{I} = 0{\cdot}20\ \mathrm{mA} = 0{\cdot}20 \times 10^{-3}\ \mathrm{A}$

Now, $$\mathrm{I} = \frac{k}{n\,\mathrm{B\,A}}\,\alpha$$

or $$k = \frac{n\,\mathrm{B\,I\,A}}{\alpha}$$
$$= \frac{60 \times 90 \times 10^{-4} \times 0{\cdot}20 \times 10^{-3} \times 5{\cdot}0 \times 10^{-4}}{18}$$
$$= \mathbf{3{\cdot}0 \times 10^{-9}\ N\ m\ per\ degree}$$

Problem 2.19. Compare the current sensitivity and vo tage sensitivity of the following moving coil galvanometer

Meter A : $n = 30$; $\mathrm{A} = 1{\cdot}5 \times 10^{-3}\ \mathrm{m}^2$; $\mathrm{B} = 0{\cdot}25\ \mathrm{T}$; R = 20

Meter B : $n = 35$; $\mathrm{A} = 2{\cdot}0 \times 10^{-3}\ \mathrm{m}^2$; $\mathrm{B} = 0{\cdot}25\ \mathrm{T}$; R = 30

You are given that the springs in the two meters ha the same torsional constants.

Sol. *For meter A :* *For meter B :*

$n_1 = 30$; $\mathrm{A}_1 = 1{\cdot}5 \times 10^{-3}\ \mathrm{m}^2$ $n_2 = 35$; $\mathrm{A}_2 = 2{\cdot}0 \times 10^{-3}$

$\mathrm{B}_1 = 0{\cdot}25\mathrm{T}$; $\mathrm{R}_1 = 20\Omega$ $\mathrm{B}_2 = 0{\cdot}25\ \mathrm{T}$; $\mathrm{R}_2 = 30\ \Omega$

Current sensitivity of a meter, $\dfrac{\alpha}{\mathrm{I}} = \dfrac{n\,\mathrm{B\,A}}{k}$

$$\therefore \quad \frac{\text{current sensitivity of meter A}}{\text{current sensitivity of meter B}} = \frac{n_1\,\mathrm{B}_1\,\mathrm{A}_1}{k_1} \times \frac{k_2}{n_2\,\mathrm{B}_2\,\mathrm{A}_2}$$

Now, springs in the two meters have same value of *k* i

$$k_1 = k_2$$

$$\therefore \quad \frac{\text{current sensitivity of meter A}}{\text{current sensitivity of meter B}} = \frac{n_1\,\mathrm{B}_1\,\mathrm{A}_1}{n_2\,\mathrm{B}_2\,\mathrm{A}_2}$$
$$= \frac{30 \times 0{\cdot}25 \times 1{\cdot}5 \times 10^{-3}}{35 \times 0{\cdot}25 \times 2{\cdot}0 \times 10^{-3}} = \frac{45}{70} = \frac{9}{14}$$

Voltage sensitivity of a meter, $\dfrac{\alpha}{\mathrm{IR}} = \dfrac{n\,\mathrm{B\,A}}{k\mathrm{R}}$

$$\therefore \quad \frac{\text{voltage sensitivity of meter A}}{\text{voltage sensitivity of meter B}} = \frac{n_1\,\mathrm{B}_1\,\mathrm{A}_1}{k_1\,\mathrm{R}_1} \times \frac{k_2\,\mathrm{R}_2}{n_2\,\mathrm{B}_2\,\mathrm{A}_2}$$

Since $k_1 = k_2$, we have

$$\frac{\text{voltage sensitivity of meter A}}{\text{voltage sensitivity of meter B}} = \frac{n_1\,\mathrm{B}_1\,\mathrm{A}_1\,\mathrm{R}_2}{n_2\,\mathrm{B}_2\,\mathrm{A}_2\,\mathrm{R}_1}$$
$$= \frac{9}{14} \times \frac{30}{20} = \frac{27}{28}$$

Problem 2.20. The current sensitivity of a moving co galvanometer increases by 20%, when its resistance increased by a factor of two. Calculate by what factor, tl voltage sensitivity changes. (*C.B.S.E. 1998*

Sol. Consider that the moving coil galvanometer consis of a coil of *n* turns and possesses area A and resistance When a potential difference V is applied, suppose that current I flows through the galvanometer and the coil deflec through angle α. Then, current sensitivity of the galvanometer, $\frac{\alpha}{I} = \frac{nAB}{k}$ ...(*i*)

and voltage sensitivity of the galvanometer,

$$\frac{\alpha}{V} = \frac{\alpha}{IR} = \frac{nAB}{kR} \quad ...(ii)$$

The resistance of the galvanometer can be increased by increasing n or A or both n and A. Suppose that the resistance of the galvanometer increases by a factor 2 *i.e.* becomes R′= 2 R, when the values of n and A are changed to $n'$and A′respectively. When the same potential difference V is applied, suppose that current I′ flows through the galvanometer and the coil deflects through angle α'.

Then, new current sensitivity of the galvanometer,

$$\frac{\alpha'}{I'} = \frac{n'A'B}{k} \quad ...(iii)$$

and new voltage sensitivity of the galvanometer,

$$\frac{\alpha'}{V} = \frac{\alpha'}{I'R'} = \frac{n'A'B}{2kR} \quad ...(iv)$$

Since on increasing resistance from R to R′ = 2 R, the current sensitivity increases by 20%, it follows that

$$\frac{\alpha'}{I'} = \frac{120}{100} \cdot \frac{\alpha}{I}$$

Using equations (*i*) and (*iii*), we have

$$\frac{n'A'B}{k} = \frac{120}{100} \cdot \frac{nAB}{k}$$

$$\text{or} \qquad n'A' = \frac{6nA}{5} \quad ...(v)$$

From equations (*iv*) and (*v*), we have

$$\frac{\alpha'}{V} = \frac{6nA}{5} \times \frac{B}{2kR} = \frac{3nAB}{5kR} \quad ...(vi)$$

From equations (*ii*) and (*vi*), we have

$$\frac{\alpha'}{V} = \frac{3}{5} \cdot \frac{\alpha}{V}$$

i.e. on increasing resistance of the glavanometer, the voltage sensitivity decreases by a factor of 3/5 *i.e.* it becomes 60% or decreases by 40%.

Type I. On conversion of galvanometer into ammeter and voltmeter

Problem 2.21. A galvanometer of resistance 15 Ω gives full scale deflection for a current of 2 mA. Calculate the shunt resistance needed to convert it to an ammeter of range 0 – 5 A. (*C.B.S.E. 1991*)

Sol. Here, G = 15 Ω ; I_g = 2 mA = 2× 10^{-3} A; I = 5 A

$$\text{Now,} \qquad S = \frac{I_g G}{I - I_g} = \frac{2 \times 10^{-3} \times 15}{5 - 2 \times 10^{-3}} = 0 \cdot 006\,\Omega$$

Problem 2.22. A galvanometer has a resistance of 100 ohm. A difference of potential of 50 millivolt between its terminals gives a full scale deflection. Calculate shunt resistance, which will enable the instrument to read upto 5 ampere.

Sol. Here, V = 50 mV = 50 × 10^{-3} V ; G = 100 Ω

$$\therefore \qquad I_g = \frac{V}{G} = \frac{50 \times 10^{-3}\,V}{100\,\Omega} = 5 \times 10^{-4}\,A$$

$$\text{Now,} \qquad S = \frac{I_g G}{I - I_g} = \frac{5 \times 10^{-4} \times 100}{5 - 5 \times 10^{-4}} = 0 \cdot 01\,\Omega$$

Problem 2.23. An ammeter of resistance 100 Ω can measure a maximum current of 5 mA . What will you do to measure a maximum current of 5 A with it ? (*P.S.S.C.E. 1994*)

Sol. The given ammeter may be considered as a galvanometer of resistance 100 Ω, which can measure a maximum current of 5 mA. Thus,

G = 100 Ω ; I_g = 5 mA = 5 × 10^{-3} A and I = 5 A

For this, a suitable small resistance S has to be connected in parallel to the coil of the given galvanometer. It is given by

$$S = \frac{I_g \times G}{I - I_g} = \frac{5 \times 10^{-3} \times 100}{5 - 5 \times 10^{-3}} = 0 \cdot 1\,\Omega$$

Problem 2.24. A galvanometer has a resistance of 5 Ω and a full scale deflection is produced by 15 mA. Calculate what resistance must be used to enable the galvanometer to read (*a*) 1·5 A ; (*b*) 1·5 volt ? (*Pre-degree Kerala, 1992*)

Sol. Here, G = 5 Ω; I_g = 15 mA = 15 × 10^{-3} A

(*a*) ***To enable galvanometer to read 1·5 A*** :

Here, = 1·5 A

The required resistance,

$$S = \frac{I_g \times G}{I - I_g} = \frac{15 \times 10^{-3} \times 5}{1 \cdot 5 - 15 \times 10^{-3}} = 0 \cdot 05\,\Omega \quad \textbf{(in parallel)}$$

(*b*) ***To enable galvanometer to read 1·5 V*** :

Here, V = 1·5 volt

The required resistance,

$$R = \frac{V}{I_g} - G = \frac{1 \cdot 5}{15 \times 10^{-3}} - 5 = 95\,\Omega \ \textbf{(in series)}$$

Problem 2.25. A moving coil galvanometer of resistance 10 ohm produces full scale deflection, when a current of 25 mA is passed through it. Describe showing full calculations, how will you convert the galvanometer into (*a*) a voltmeter reading upto 120 V (*b*) an ammeter reading upto 20 A. (*I.S.C.E. 1994*)

Sol. Here, G = 10 Ω ; I_g = 24 mA = 25 × 10^{-3} A

(*a*) ***To convert the galvanometer into voltmeter reading upto 120 V.*** To convert a galvanometer into voltmeter of range V, a large resistance R has to be connected in series to it. The value of R is given by

$$R = \frac{V}{I_g} - G$$

Here, V = 120 volt

$$\therefore \qquad R = \frac{120}{25 \times 10^{-3}} - 10 = 4790\,\Omega$$

(*b*) ***To convert galvanometer into ammeter reading upto 20 A.*** To convert a galvanometer into ammeter of range I, a small resistance S has to be connected in parallel to it. The value of S is given by

$$S = \frac{I_g G}{I - I_g}$$

Here, I = 20 A

$$\therefore \qquad S = \frac{25 \times 10^{-3} \times 10}{20 - 25 \times 10^{-3}} = 0 \cdot 0125\,\Omega$$

Type J. On Ammer and Voltmeter

Problem 2.26. A battery of e.m.f. 3 volt and internal resistance *r* is connected in series with a resistor of 55 Ω

through an ammeter of resistance 1 Ω. The ammeter reads 50 mA. Draw the circuit diagram and calculate the value of *r*. *(H.S.S.C.E. 2002 ; Pre-degree Kerala, 1994)*

Sol. The given battery, ammeter and the resistor are connected as shown in Fig. 2.22.

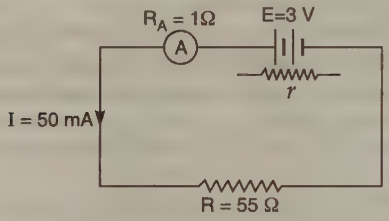

Fig. 2.22

Let R_A be the resistance of the ammeter. Then, the current in the circuit is given by

$$I = \frac{E}{R + R_A + r}$$

Here, $E = 3\text{ V}, R = 55\ \Omega, R_A = 1\ \Omega,$

$I = 50\text{ mA} = 50 \times 10^{-3}\text{ A}$

$$\therefore\ 50 \times 10^{-3} = \frac{3}{55 + 1 + r} = \frac{3}{56 + r}$$

or $$r = \frac{3}{50 \times 10^{-3}} - 56 = 60 - 56 = \mathbf{4\ \Omega}$$

Problem 2.27. In a circuit shown in Fig. 2.23 ; a voltmeter reads 30 V, when it is connected across 400 ohm resistance. Calculate what the same voltmeter will read, when connected across the 300 ohm resistance ? *(P.S.S.C.E. 1995)*

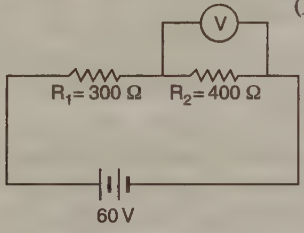

Fig. 2.23

Sol. Here, $E = 60\text{ V}\ ;\ R_1 = 400\ \Omega\ ;\ R_2 = 300\ \Omega$,

Reading of voltmeter, when connected across R_1,

$V_1 = 30\text{ V}$

Let R_V be the internal resistance of the voltmeter. If R is the resistance of the parallel combination of R_V and R_1, then

$$R = \frac{R_V \times R_1}{R_V + R_1} = \frac{R_V \times 400}{R_V + 400}$$

The current in the circuit,

$$I = \frac{E}{R_2 + R} = \frac{60}{300 + \dfrac{R_V \times 400}{R_V + 400}} = \frac{60\,(R_V + 400)}{700\,R_V + 12000}$$

Since potential difference across R is measured to be 30 V,

$IR = 30$

or $$\frac{60\,(R_V + 400)}{700\,R_V + 12000} \times \frac{400\,R_V}{(R_V + 400)} = 30 \text{ or } R_V = 1200\ \Omega$$

Suppose that when the voltmeter is connected across R_2, the resistance of their parallel combination becomes R′. Then,

$$R' = \frac{R_V \times R_2}{R_V + R_2} = \frac{1200 \times 300}{1200 + 300} = 240\ \Omega$$

If I′ is current in the circuit in this case, then

$$I' = \frac{E}{R' + R_1} = \frac{60}{240 + 400} = \frac{3}{32}\text{ A}$$

Therefore, reading of the voltmeter, when connecte across R_2,

$$V = I'R' = \frac{3}{32} \times 240 = \mathbf{22{\cdot}5\ V}$$

Problem 2.28. A voltmeter V of resistance 400 Ω i used to measure the potential difference across a 100 resistor in the circuit as shown in Fig. 2.24.

(*a*) What will be the reading on the voltmeter ? (b Calculate the potential difference across 100 Ω resisto before the voltmeter is connected. *(C.B.S.E. 1998*

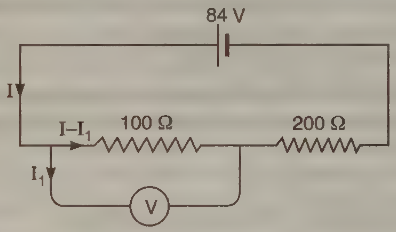

Fig. 2.24

Sol. Here, resistance of voltmeter, $R_V = 400\ \Omega$

E.M.F. of the battery, E = 84 V

Suppose that a current I flows through the main circui and a part I_1 of this current flows through the voltmeter a shown in the figure. Then, the remaining part $(I - I_1)$ will flov through the resistance of 100 Ω .

(*a*) Since voltmeter and 100 Ω resistance are connecte in parallel to each other, the potential drop across them i same *i.e.*

$I_1 \times R_V = (I - I_1) \times 100$

or $I_1 \times 400 = (I - I_1) \times 100$

or $I_1 = I/5$ ...(*i*

Also, if R is the equivalent resistance of the paralle combination of R_V (resistance of voltmeter) and 100 resistance, then

$$\frac{1}{R} = \frac{1}{R_V} + \frac{1}{100} = \frac{1}{400} + \frac{1}{100} = \frac{5}{400}$$

or $R = 80\ \Omega$

If R_1 is the total resistance of the circuit, then

$R_1 = R + 200 = 80 + 200 = 280\ \Omega$

Hence, current in the main circuit, $I = \dfrac{E}{R_1} = \dfrac{84}{280} = 0{\cdot}3\text{ A}$

Substituting for I in equation (*i*), we have

$I_1 = 0{\cdot}3/5 = 0{\cdot}06\text{ A}$

Therefore, reading of the voltmeter = potential dro across voltmeter $= I_1 \times R_V = 0{\cdot}06 \times 400 =$ **24 V**

(*b*) When the voltmeter is not connected, the tota resistance of the circuit will become,

$R_2 = 100 + 200 = 300\ \Omega$

If I_2 is current in the circuit, then

$$I_2 = \frac{E}{R_2} = \frac{84}{300} = 0{\cdot}28\text{ A}$$

Hence, potential difference across 100 Ω resistance

$$= I_2 \times 100 = 0{\cdot}28 \times 100 = \mathbf{28\ V}$$

Problem 2.29. (*a*) A d.c. supply of 120 V is connected to a large resistance X. A voltmeter of resistance 10 k Ω placed in series in the circuit reads 4 V. What is the value of X ? *(P.S.S.C.E. 1992)*

(*b*) What do you think is the purpose in using a voltmeter, instead of an ammeter, to determine the large resistance X ? *(Text Problem)*

Sol. (*a*) Here, $E = 120\ V$; $R_V = 10\ k\Omega = 10^4\ \Omega$

When the voltmeter is put in series with unknown resistance X,

the total resistance in the circuit $= R_V + X = 10^4 + X$

The current in the circuit, $I = \dfrac{E}{R_V + X} = \dfrac{120}{10^4 + X}$

Therefore, potential difference across the voltmeter itself

$$= I \times R_V = \frac{120}{10^4 + X} \times 10^4$$

Since reading of the voltmeter is 4 V, we have

$$\frac{120}{10^4 + X} \times 10^4 = 4$$

or $\qquad 10^4 + X = 30 \times 10^4$

or $\qquad X = 29 \times 10^4 = \mathbf{290\ k\Omega}$

(*b*) If an ammeter is used, then its reading will be too small to be measured.

TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 2.30. A magnetic field set up using Helmholtz coils is uniform in a small region and has a magnitude of 0·75 T. In the same region, a uniform electrostatic field is maintained in a direction normal to the common axis of the coils. A narrow beam of (single-species) charged particles all accelerated through 15 kV enters this region in a direction perpendicular to both the axis of the coils and the electrostatic field. If the beam remains undeflected, when the electrostatic field is $9{\cdot}0 \times 10^5\ V\ m^{-1}$; make a simple guess as to what the beam contains. Why is the answer not unique ? *(Text Problem)*

Sol. Here, $B = 0{\cdot}75\ T$; $E = 9{\cdot}0 \times 10^5\ V\ m^{-1}$

Let *e* be charge, *m* be mass and *v* be velocity of the charged particles.

Since beam of charged particles remains undeflected, the force on a charged particle due to magnetic and electric fields must be equal and opposite. Therefore,

$$B\,e\,v = E\,e$$

or $\qquad v = \dfrac{E}{B} = \dfrac{9{\cdot}0 \times 10^5}{0{\cdot}75} = 1{\cdot}12 \times 10^6\ m\,s^{-1} \qquad ...(i)$

Now, kinetic energy of proton, $\frac{1}{2} m v^2 = V e$

Here, $\qquad V = 15\ kV = 15 \times 10^3\ V$

$$\therefore \quad \frac{1}{2} m v^2 = 15 \times 10^3 \times e$$

or $\qquad \dfrac{e}{m} = \dfrac{v^2}{30 \times 10^3} \qquad ...(ii)$

From equations (*i*) and (*ii*), we have

$$\frac{e}{m} = \frac{(1{\cdot}2 \times 10^6)^2}{30 \times 10^3} = 4{\cdot}8 \times 10^7\ C\,kg^{-1}$$

For proton, the value of e/m is $9{\cdot}6 \times 10^7\ C\,kg^{-1}$. It follows that the charged particle under reference has the value of e/m half of that for proton and therefore beam may be of **deutrons** (assuming that charge on particle is $1{\cdot}6 \times 10^{-19}$ C).

The answer is not unique because this ratio of charge to mass *i.e.* $4{\cdot}8 \times 10^7\ C\,kg^{-1}$ can be satisfied by many other charged particles such as He^{++}, Li^{+++}, etc.

Problem 2.31. A monoenergetic (18 keV) electron beam initially in the horizontal direction is subject to a horizontal magnetic field of 0·40 G normal to the initial direction. Estimate the up or down deflection of the beam over a distance of 30 cm. Given, $m = 9{\cdot}11 \times 10^{-31}$ kg and $e = 1{\cdot}60 \times 10^{-19}$ C.

Sol. Here, $m = 9{\cdot}11 \times 10^{-31}$ kg ; $e = 1{\cdot}60 \times 10^{-19}$ C ;

$$B = 0{\cdot}40\ G = 0{\cdot}40 \times 10^{-4}\ T\ ;$$

$$\frac{1}{2} m v^2 = 18\ keV = 18 \times 1{\cdot}6 \times 10^{-16}\ J$$

Suppose electron moves along a circular path of radius *r* under the effect of magnetic field.

Then, $\qquad \dfrac{m v^2}{r} = B\,e\,v$

or $\qquad r = \dfrac{m v}{B e} = \dfrac{\sqrt{2 m \times \frac{1}{2} m v^2}}{B e}$

$$= \frac{\sqrt{2 \times 9{\cdot}11 \times 10^{-31} \times 18 \times 1{\cdot}6 \times 10^{-16}}}{0{\cdot}40 \times 10^{-4} \times 1{\cdot}60 \times 10^{-19}}$$

$$= 11{\cdot}32\ m$$

Fig 2.25 shows an electron covering a circular path PQ (= 30 cm = 0·3 m) and of radius OP (= OQ =11·32 m).

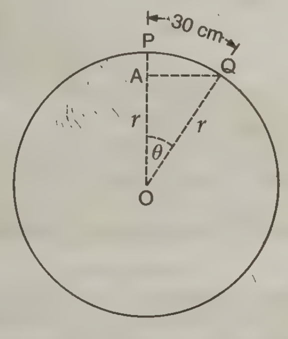

Fig. 2.25

It follows that the electron will undergo a deflection PA in downward direction, while it covers a distance PQ. If *θ* is angle subtended by PQ at the point O, then

$$PA = OP - OA = r - r\cos\theta = r\,(1 - \cos\theta)$$

Now, $\qquad \theta = \dfrac{\overset{\frown}{PQ}}{OP} = \dfrac{0{\cdot}30}{11{\cdot}32} = 0{\cdot}0265\ rad = 1{\cdot}52°$

$$\therefore \quad PA = 11{\cdot}32\,(1 - \cos 1{\cdot}52°) = 11{\cdot}32\,(1 - 0{\cdot}99965)$$

$$= \mathbf{3{\cdot}962 \times 10^{-4}\ m = 4\ mm}$$

Problem 2.32. A straight horizontal conducting rod of length 0·45 m and mass 60 g is suspended by the vertical wires at its ends. A current of 5·0 A is set up in the rod through the wires.

(*a*) What magnetic field should be set up normal to the conductor in order that the tension in the wires is zero ?

(*b*) What will be the total tension in the wires, if the direction of current is reversed, keeping the magnetic field same as before ? (Ignore the mass of the wire) $g = 9{\cdot}8\ \text{m s}^{-2}$. *(Text Problem)*

Sol. Here, mass of rod, $m = 60\text{ g} = 60 \times 10^{-3}\text{ kg}$;

$l = 0{\cdot}45\text{ m}; \text{I} = 5{\cdot}0\text{ A}$

(*a*) There will be no tension in the supporting wires, if the force on the rod due to the magnetic field is equal to the weight of the rod and is in vertically upward direction. Fleming's left hand rule tells that the magnetic field should be applied along horizontal. Therefore, for no tension in supporting wires,

$$\text{B I } l = mg$$

or $$\text{B} = \frac{mg}{\text{I } l} = \frac{60 \times 10^{-3} \times 9{\cdot}8}{5{\cdot}0 \times 0{\cdot}45} = \mathbf{0{\cdot}261\ T}$$

(*b*) If the direction of the current is reversed, force on the rod will act in the direction of its weight and hence tension in the supporting wires will become

$$\text{T} = 2 \times \text{weight of the rod} = 2 \times 60 \times 10^{-3} \times 9{\cdot}8$$
$$= \mathbf{1{\cdot}176\ N}$$

Problem 2.33. On a smooth plane inclined at 30° with the horizontal, a thin current-carrying metallic rod is placed parallel to the horizontal ground. The plane is located in a uniform magnetic field of 0·15 T in the vertical direction. For what value of current can the rod remain stationary ? The mass per unit length of the rod is $0{\cdot}30\ \text{kg m}^{-1}$. *(Text Problem)*

Sol. A rod XY of length say l is placed on an inclined plane as shown in Fig. 2.26.

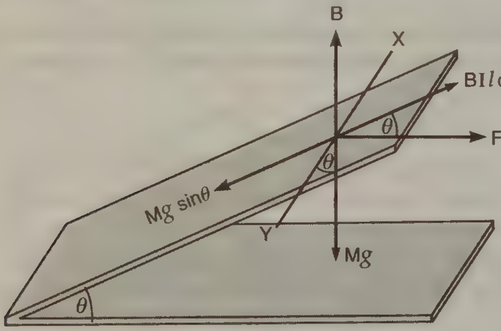

Fig. 2.26

Let θ be inclination of the inclined plane with the horizontal. If current I flows through the rod XY from end Y to X, then following forces act on the wire XY :

(*i*) Weight Mg acts vertically downward. It follows that weight Mg makes an angle θ with normal to inclined plane.

(*ii*) Due to magnetic field, force B I l acts parallel to horizontal and towards right. The force B I l makes an angle θ with the inclined plane.

The rod will remain stationary, if component of the weight Mg of the rod along the inclined plane in downward direction is just balanced by the component of force B I l along the inclined plane in upward direction *i.e.*

$$\text{M}g \sin\theta = \text{B } l \text{ I} \cos\theta$$

If m is mass per unit length of the rod, then

$$\text{M} = m\,l$$

$$\therefore \quad m\,l\,g \sin\theta = \text{B I } l \cos\theta$$

or $$\text{I} = \frac{m\,g \tan\theta}{\text{B}}$$

Here, $\text{B} = 0{\cdot}15\text{ T}\ ;\ m = 0{\cdot}30\text{ kg m}^{-1}$;

$\theta = 30°\ ;\ g = 9{\cdot}8\text{ m s}^{-2}$;

$$\therefore \quad \text{I} = \frac{0{\cdot}30 \times 9{\cdot}8 \times \tan 30°}{0{\cdot}15} = \frac{0{\cdot}30 \times 9{\cdot}8 \times 0{\cdot}5774}{0{\cdot}15}$$
$$= \mathbf{11{\cdot}32\ A}$$

Problem 2.34. A short conductor of length 5·0 cm is placed parallel to a long conductor of length 1·5 m nea its centre. The conductors are carrying currents 4·0 A and 3·0 A respectively in the same direction. What is the total force experienced by the long conductor, when they are 3· cm apart ? *(Text Problem)*

Sol. Here, $\text{I}_1 = 4{\cdot}0\text{ A}$ (through short conductor);

$\text{I}_2 = 3{\cdot}0\text{ A}$ (through long conductor)

$r = 3{\cdot}0\text{ cm} = 3{\cdot}0 \times 10^{-2}\text{ m}$

Force acting per unit length on the short conductor due to a long conductor is given by

$$\text{F} = \frac{\mu_0}{4\pi} \times \frac{2\text{I}_1\text{I}_2}{r}$$

$$\therefore \quad \text{F} = \frac{10^{-7} \times 2 \times 4{\cdot}0 \times 3{\cdot}0}{3{\cdot}0 \times 10^{-2}} = 8{\cdot}0 \times 10^{-5}\text{ N}$$

Therefore, total force on short conductor,

$$\text{F}' = \text{F} \times \text{length of the short conductor}$$
$$= 8{\cdot}0 \times 10^{-5} \times (5{\cdot}0 \times 10^{-2})$$
$$= \mathbf{4{\cdot}0 \times 10^{-6}\ N\ (attractive\ force)}$$

According to Newton's third law, the long conducto will also experience an equal attractive force **($4{\cdot}0 \times 10^{-6}$ N)** due to the short conductor.

Problem 2.35. A rectangular loop of sides 25 cm and 10 cm carrying a current of 15 A is placed with its longer side parallel to a long straight conductor 2·0 cm apart carrying a current of 25 A. What is the net force on the loop ? *(Pre-degree Kerala, 1991 ; Text Problem)*

Sol. Consider the rectangular loop ABCD placed nea a long straight conductor XY as shown in Fig. 2.27.

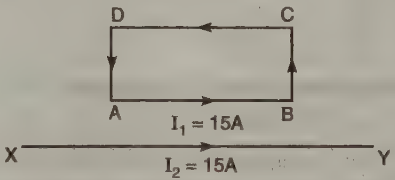

Fig. 2.27

The arm AB will get attracted, while CD will get repelled. Forces on arms BC and AD will cancel each other.

Here, $\text{AB} = 25\text{ cm} = 25 \times 10^{-2}\text{ m}$;

$\text{BC} = 10\text{ cm} = 10 \times 10^{-2}\text{ m}$;

Distance of AB from XY,

$r_1 = 2{\cdot}0\text{ cm} = 2{\cdot}0 \times 10^{-2}\text{ m}$;

Distance of CD from XY,

$r_2 = 10{\cdot}0 + 2{\cdot}0 = 12{\cdot}0\text{ cm} = 12{\cdot}0 \times 10^{-2}\text{ m}$;

Current through the rectangular loop, $\text{I}_1 = 15\text{ A}$;

Current through the long wire XY, $\text{I}_2 = 25\text{ A}$

Force on side AB, $F_1 = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r_1}$

$\times$ length of the conductor AB

$$= \frac{10^{-7} \times 2 \times 15 \times 25}{2\cdot 0 \times 10^{-2}} \times 25 \times 10^{-2}$$

$= 9\cdot 375 \times 10^{-4}$ N (attractive)

Force on side CD, $F_2 = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r_2}$

$\times$ length of the conductor CD

$$= \frac{10^{-7} \times 2 \times 15 \times 25}{12\cdot 0 \times 10^{-2}} \times 25 \times 10^{-2}$$

$= 1\cdot 5625 \times 10^{-4}$ N (repulsive)

Therefore, net force on the loop,

$$F = F_1 - F_2 = 9\cdot 375 \times 10^{-4} - 1\cdot 5625 \times 10^{-4}$$

$$= \mathbf{7\cdot 8125 \times 10^{-4}\ N\ (towards\ XY)}$$

Problem 2.36. A current balance (or ampere balance) is a device for measuring currents. The current to be measured is arranged to go through two long parallel wires of equal lengths in opposite directions, one of which is linked to the pivot of the balance. The resulting repulsive force on the wire is balanced by putting a suitable mass in the scale pan hanging on the other side of the pivot. In one measurement, the mass in the scale pan is 30·0 g, the length of the wires is 50·0 cm each and the separation between them is10·0 mm. What is the value of the current being measured ? Take $g = 9\cdot 8$ m s^{-2} and assume that the arms of the balance are equal. *(Text Problem)*

Sol. Here, length of each of the two wires,

$$l = 50 \text{ cm} = 0\cdot 5 \text{ m};$$

distance between the two wires, $r = 10$ mm $= 10^{-2}$ m

Since length of each wire is quite large as compared to distance between them, the two wires may be considered as straight long conductors. Therefore, force experienced by unit length of one wire due to the other is given by

$$F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r}$$

and total force on the wire attached to the scale pan,

$$F' = F \times l = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r} l$$

When the pan is balanced, $F' = M g$

or $$\frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r} l = M g$$

Here, $M = 30\cdot 0 \text{ g} = 30\cdot 0 \times 10^{-3}$ kg ; $g = 9\cdot 8$ m s^{-2} ;

$l = 0\cdot 5$ m ; $r = 10^{-2}$ m

Since the same current flows through the two wires,

$$I_1 = I_2 = I \text{ (say)}$$

$$\therefore\ 10^{-7} \times \frac{2 I \times I}{10^{-2}} \times 0\cdot 5 = 30\cdot 0 \times 10^{-3} \times 9\cdot 8$$

or $$I = \sqrt{\frac{30\cdot 0 \times 10^{-3} \times 9\cdot 8 \times 10^{-2}}{10^{-7} \times 2 \times 0\cdot 5}} = \mathbf{171\cdot 46\ A}$$

Problem 2.37. A solenoid 60 cm long and of radius 4·0 cm has 3 layers of windings of 300 turns each. A 2·0 cm long wire of mass 2·5 g lies inside the solenoid near its centre and normal to its axis ; both the wires and the axis of the solenoid are in the horizontal plane. The wire is connected through two leads parallel to the axis of the solenoid to an external battery which supplies a current of 6·0 A in the wire. What value of current in the windings of the solenoid can support the weight of the wire ? $g = 9\cdot 8$ m s^{-2}. *(Text Problem)*

Sol. Let I be the current passed through the solenoid.

Then, magnetic field produced along axis of the solenoid,

$$B = \mu_0 n I$$

Here, total number of turns $= 300 \times 3 = 900$;

length $= 60$ cm $= 0\cdot 6$ m

Therefore, number of turns per unit length,

$$n = \frac{\text{total number of turns}}{\text{length of solenoid}} = \frac{900}{0\cdot 6}$$

$$= 1500 \text{ turns m}^{-1}$$

Now, $$B = \mu_0 n I = 4\pi \times 10^{-7} \times 1500 \times I$$

$$= 6\pi \times 10^{-4} I \text{ tesla}$$

Length of the wire placed inside the solenoid,

$$l = 2\cdot 0 \text{ cm} = 0\cdot 02 \text{ m}$$

Current through the wire, $I' = 6\cdot 0$ A

Force on the wire,

$$F = B I' l = (6\pi \times 10^{-4} I) \times 6\cdot 0 \times 0\cdot 02$$

$$= 2\cdot 262 \times 10^{-4} I \text{ newton}$$

The weight of the wire will be supported, if force F due to magnetic field on the current carrying wire is just equal and opposite to the weight of wire *i.e.*

$$2\cdot 262 \times 10^{-4} I = m g$$

Here, $m = 2\cdot 5 \text{ g} = 2\cdot 5 \times 10^{-3}$ kg

Therefore, $2\cdot 262 \times 10^{-4} I = 2\cdot 5 \times 10^{-3} \times 9\cdot 8$

or $$I = \frac{2\cdot 5 \times 10^{-3} \times 9\cdot 8}{2\cdot 262 \times 10^{-4}} = \mathbf{108\cdot 3\ A}$$

Problem 2.38. The coil of a galvanometer is $0\cdot 02 \times 0\cdot 08$ m^2. It consists of 200 turns of fine wire and is in a magnetic field of 0·2 tesla. The restoring torque constant of the suspension fibre is 10^{-6} N m per degree. Assuming the magnetic field to be radial,

(*i*) what is the maximum current that can be measured by this galvanometer, if the scale can accommodate 30° deflection ? (*ii*) what is the smallest current that can be detected, if the minimum observable deflec-tion is 0·1° ? *(Text Problem)*

Sol. Here $A = 0\cdot 02 \times 0\cdot 08 = 1\cdot 6 \times 10^{-3}$ m^2 ;

$n = 200$; $B = 0\cdot 2$ T

Restoring torque constant of the suspension fibre,

$$k = 10^{-6} \text{ N m per degree}$$

(*i*) Maximum deflection, $\theta_{max} = 30°$

Let I_{max} be the maximum current that can be measured by the galvanometer. Then,

$$n B A I_{max} = k \theta_{max}$$

or $$I_{max} = \frac{k \theta_{max}}{n B A} = \frac{10^{-6} \times 30}{200 \times 0\cdot 2 \times 1\cdot 6 \times 10^{-3}}$$

$$= \mathbf{4\cdot 69 \times 10^{-4}\ A}$$

(ii) Minimum deflection, $\theta_{min} = 0\cdot1°$

Let I_{min} be the minimum current that can be measured by the galvanometer. Then,

$$I_{min} = \frac{k\,\theta_{min}}{n\,B\,A} = \frac{10^{-6}\times0\cdot1}{200\times0\cdot2\times1\cdot6\times10^{-3}} = \mathbf{1{\cdot}56\times10^{-6}\ A}$$

Problem 2.39. A voltmeter reads 5·0 V at full scale deflection and is graded according to its resistance per volt at full scale deflection as 5000 Ω V^{-1}. How will you convert it into a voltmeter that reads 20 V at full scale deflection ? *(C.B.S.E. 2001 S)*

Will it still be graded as 5000 Ω s^{-1}? Will you prefer this voltmeter to one that is graded as 2000 Ω V^{-1}?

(Text Problem)

Sol. Resistance per volt at full scale deflection

$$= 5000\ \Omega\ V^{-1}$$

Therefore, current for maximum deflection*,

$$I_g = \frac{1}{5000} = 2\times10^{-4}\ A$$

Reading of the voltmeter at full scale deflection = 5 V

Therefore, resistance of the instrument,

$$G = \frac{5}{2\times10^{-4}} = 2\cdot5\times10^{4}\ \Omega$$

New range of voltmeter, V = 20 volt

Let R be the resistance that should be connected in series, so that voltmeter may read upto 20 V.

Then, $$R = \frac{V}{I_g} - G = \frac{20}{2\times10^{-4}} - 2\cdot5\times10^{4}$$

$$= 10\times10^{4} - 2\cdot5\times10^{4} = \mathbf{7{\cdot}5\times10^{4}\ \Omega}$$

Resistance of the new voltmeter,

$$R + G = 7\cdot5\times10^{4} + 2\cdot5\times10^{4} = 10^{5}\ \Omega$$

Resistance per volt of the new voltmeter

$$= \frac{10^{5}}{20} = \mathbf{5000\ \Omega\ V^{-1}}$$

Therefore, new voltmeter will be still graded as **5000 Ω V^{-1}.**

A voltmeter graded as 5000 Ω V^{-1} is better than one graded as 2000 Ω V^{-1}. It is because, higher the resistance per volt, lesser is the current it draws from the circuit and hence the better it is.

Problem 2.40. A voltmeter of resistance 400 Ω connected for measurement to a section of a circuit having a resistance of 20 Ω shows a reading of 100 V. What is the error in the reading of the voltmeter, if the current in the main circuit is assumed to remain constant before and after connecting the voltmeter ?

Ans. Here, potential difference across R as measured by the voltmeter, V′ = 100 V

When the voltmeter is connected across the resistance of 20 Ω, it draws a part of the total current I flowing through the circuit. Let I_1 be the current drawn by the voltmeter as shown in Fig. 2.28.

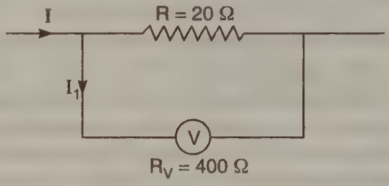

Fig. 2.28

Then, $$I_1 = \frac{V'}{R_V} = \frac{100}{400} = 0\cdot25\ A$$

Therefore, on connecting the voltmeter, decrease in the potential difference across the resistance,

$$\Delta V = I_1\times20 = 0\cdot25\times20 = 5\ V$$

Hence, potential difference across the resistance before the voltmeter was connected,

$$V = V' + \Delta V = 100 + 5 = 105\ V$$

Since the voltmeter measures potential difference across R as 100 V, error in the reading of the voltmeter is **5 V.**

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 2.01. An electric charge enters in electric field at right angles to the direction of electric field. What is the nature of the path followed ?

Ans. The electric charge will move along a parabolic path.

Q. 2.02. What is the magnitude of transverse acceleration produced in the motion of the electric charge, when it passes through the electric field ?

Ans. If a charge q having mass m passes transversely through an electric field E, then

$$\text{acceleration, } a = \frac{qE}{m}$$

Q. 2.03. What is magnetic Lorentz force ? *(P.S.S. C.E. 2001)*

Ans. The force experienced by a charged particle, when moving inside magnetic field is called magnetic Lorentz force. It is given by

$$\vec{F} = q(\vec{v}\times\vec{B})$$

The magnitude of force is given by

$$F_m = B\,q\,v\sin\theta$$

Q. 2.04. In a chamber of uniform magnetic field $\vec{B}$, an electron beam enters with velocity $\vec{v}$. Write the expression for the force experienced by the electrons. *(H.S.S. C.E. 2002)*

Ans. If $-e$ is charge on the electron, then force on the electron is given by

$$\vec{F} = -e(\vec{v}\times\vec{B})$$

Q. 2.05. The force $\vec{F}$ experienced by a particle of charge e moving with velocity $\vec{v}$ in a magnetic field $\vec{B}$ is given by $\vec{F} = e(\vec{v}\times\vec{B})$. Of these, name the pairs of vectors, which are always at right angles to each other. *(C.B.S.E. 1998)*

Ans. The pair of vectors $\vec{v}$ and $\vec{F}$; and the pair $\vec{B}$ and $\vec{F}$ are always at right angles to each other.

---

*I_g = 1/resistance per volt at full scale deflection.

Q. 2.06. What is the magnitude of force on a charge moving with a velocity $\vec{v}$ in a magnetic field $\vec{B}$? (*C.B.S.E. 1991*)

Ans. Refer to VSQ 2.03. The magnitude of force on the moving charge due to magnetic field is given by

$$F_m = B\,q\,v \sin\theta$$

If the charged particle moves at right angle to the direction of the field, then

$$F_m = B\,q\,v \qquad (\because \theta = 90°)$$

Q. 2.07. A particle of charge q moves with a velocity v at an angle θ to a magnetic field B. What is the force experienced by the particle ? (*I.S.C.E. 1993*)

Ans. Force on the charged particle, $F = B\,q\,v \sin\theta$

Q. 2.08. Under which condition, an electron moving through a magnetic field experiences maximum force ? (*H.S.S.C.E. 2002 ; 1994*)

Ans. An electron moving through a magnetic field experiences maximum force, when it moves perpendicular to the direction of magnetic field.

Q. 2.09. Under what condition is the force acting on a charge moving through a uniform magnetic field maximum ? (*H.P.S.S.C.E. 2002*)

Or

A certain proton moving through a magnetic field region experiences maximum force. When does this occur ? (*C.B.S.E. 1997*)

Ans. Again, $\vec{F} = q(\vec{v} \times \vec{B})$

Obviously, magnitude of $\vec{F}$ will be maximum, if the direction of $\vec{v}$ is perpendicular to that of $\vec{B}$.

Q. 2.10. Under what condition is the force acting on a charge moving through a uniform magnetic field minimum ? (*H.S.S.C.E. 2002 ; C.B.S.E. 1995*)

Ans. A charge moving through a magnetic field, experiences no force (minimum), when it moves along the direction of magnetic field.

Q. 2.11. What is the force experienced by a stationary charge in magnetic field ? (*H.P.S.S.C.E. 2002*)

Or

A stationary charge experiences no magnetic Lorentz force. Why ? (*P.S.S.C.E. 2001*)

Ans. Refer to VSQ 2.03. For a stationary charge, $v = 0$

$$\therefore \quad F_m = B\,q\,(0) \sin\theta = 0$$

Q. 2.12. Does an electric charge moving along the direction of magnetic field experience a force ?

Ans. Refer to VSQ 2.03. For a charge moving along the direction of magnetic field, $\theta = 0°$ *i.e.* $\sin\theta = 0$.

$$\therefore \quad F_m = B\,q\,v\,(0) = 0$$

Q. 2.13. In a certain arrangement, a proton does not get deflected, while passing through a magnetic field region. Under what condition is it possible ? (*C.B.S.E. 1997*)

Ans. Now, $\vec{F} = e(\vec{v} \times \vec{B})$

Obviously, $\vec{F}$ will be zero, if $\vec{v} \times \vec{B} = 0$ *i.e.* $\vec{v} \parallel \vec{B}$

Therefore, if a proton does not get deflected while passing through a magnetic field, it must be moving along the direction of magnetic field.

Q. 2.14. An electron is not deflected, while moving through a certain region of space. Can we be sure that there is no magnetic field in the region ? (*H.P.S.S.C.E. 2002, 1996*)

Ans. No. The electron may be moving parallel to the direction of magnetic field. In such a case, the force

$$\vec{F} = -e(\vec{v} \times \vec{B}) = 0 \qquad (\because \vec{v} \text{ is parallel to } \vec{B})$$

Q. 2.15. An electron is projected in the direction of magnetic field. How will its motion be affected by the action of magnetic field ?

Ans. Refer to VSQ 2.12. No force acts on the electron due to the magnetic field, when it is projected in the direction of magnetic field. Hence, its motion will not be affected.

Q. 2.16. What will be the path of a charged particle moving along the direction of a uniform magnetic field ? (*C.B.S.E. 1995*)

Ans. When the charged particle moves along the direction of a uniform magnetic field, it experiences no force and therefore it will move along its original straight path.

Q. 2.17. A test charge of $1{\cdot}6 \times 10^{-19}$ C is moving with velocity $\vec{v} = (2\hat{i} + 3\hat{j})\ \text{m s}^{-1}$ in a magnetic field $\vec{B} = (2\hat{i} + 3\hat{j})\ \text{Wb m}^{-2}$. Find the force acting on the test charge. (*H.S.S.C.E. 1998 S*)

Ans. Here, $e = 1{\cdot}6 \times 10^{-19}$ C ; $\vec{v} = (2\hat{i} + 3\hat{j})\ \text{m s}^{-1}$;

$$\vec{B} = (2\hat{i} + 3\hat{j})\ \text{Wb m}^{-2}.$$

Now, $\vec{F} = e(\vec{v} \times \vec{B})$

$$= 1{\cdot}6 \times 10^{-19}\,[(2\hat{i} + 3\hat{j}) \times (2\hat{i} + 3\hat{j})] = 0$$

Q. 2.18. A charged particle in a plasma trapped in a magnetic bottle leaks out after a millisecond. What is the total work done by the magnetic field during the time, the particle is trapped ?

Ans. As the force due to magnetic field on a moving charged particle always acts perpendicular to its direction of motion (velocity), no work is done by the magnetic field.

Q. 2.19. Two protons P and Q, moving with the same speed enter magnetic fields B_1 and B_2 respectively at right angles to the field directions. If B_2 is greater than B_1, for which of the protons, P and Q, the circular path in the magnetic field will have a smaller radius ? (*C.B.S.E. 1998*)

Ans. From the expression : $B\,e\,v = \dfrac{m\,v^2}{r}$,

it follows that

$$B \propto \frac{1}{r}.$$

If $B_2 > B_1$, then $r_2 < r_1$ *i.e.* in magnetic field B_2, circular path will have a smaller radius.

Q. 2.20. An electron and a proton moving with the same speed enter the same magnetic field region at right angles to the direction of the field. For which of the two particles will the radius of circular path be smaller. (*C.B.S.E. 1998*)

Ans. Again from the expression,

$$B\,e\,v = \frac{m\,v^2}{r},$$

it follows that $r \propto m$. As mass of electron is less than that of proton, radius of the circular path of **electron** will be smaller.

Q. 2.21. Write down the epxression for the Lorentz force on a charged particle.

(H.P.S.S.C.E. 1999 ; P.S.S.C.E. 1999, 1998 S)

Ans. The force experienced by a charge, when moving inside the electric and magnetic fields is called Lorentz force. It is given by

$$\vec{F} = q(\vec{E} + \vec{v} \times \vec{B})$$

Q. 2.22. Does a stationary charge experience a force in an electric field ?

Ans. A stationary charge experiences force in an electric field. It is because, the force due to electric field does not depend, whether the charge is at rest or is in motion.

The force due to electric field, $|\vec{F}_e| = |q\vec{E}| = qE$

Q. 2.23. In a field, the force experienced by a charge depends only upon the magnitude of the field and does not depend upon the velocity. Is field electric or magnetic in nature ?

Ans. Refer to VSQ 2.22. The field is electric in nature.

Q. 2.24. In a field, the force experienced by a charge depends upon its velocity and becomes zero, when it is at rest. What is the nature of the field ?

Ans. The field is magnetic in nature. It is because, force due to electric field is not affected, whether the charge is at rest or is in motion.

Q. 2.25 State the principle of cyclotron.

(P.S.S.C.E. 2001)

Ans. *It states that positive ions can acquire a large amount of energy with a comparatively smaller alternating potential difference by making them to cross the same electric field time and again by making use of a strong magnetic field.*

Q. 2.26. Does time spent by a proton inside the dee of the cyclotron depend upon (*i*) the radius of the circular path (*ii*) the velocity of the proton ?

Ans. The time spent by a proton inside the dee of a cyclotron is independent of both the radius of circular path and the velocity of the proton.

Q. 2.27. What are the primary functions of electric field and the magnetic field in a cyclotron ?

Ans. The magnetic field makes the charged particle to cross the gap between the dees again and again by making it to move along circular path, while the oscillating electric field applied across the dees accelerates the charged particle again and again.

Q. 2.28. What is meant by cyclotron frequency ?

Ans. Refer to section 2.05.

Q. 2.29. The frequency of a charge circulating inside the dees of a cyclotron does not depend upon the speed of the charge. Why ?

Ans. The radius of the circular path inside the dee increases in direct proportion to the velocity of the charge. As a result, time period of the charge and hence its frequency remains independent of the speed of the charge.

Q. 2.30. Can neutrons be accelerated in a cyclotron ? Why ? *(H.P.S.S.C.E. 1998 S)*

Ans. No, neutrons cannot be accelerated by using a cyclotron. This is because, a cyclotron can accelerate charged particles and is particularly suitable for protons and positive ions.

Q. 2.31. State Fleming's left hand rule.

(P.S.S.C.E. 2001)

Ans. Refer to section 2.07.

Q. 2.32. What is the nature of force, when the two parallel conductors carry currents in the (*i*) same direction ; (*ii*) opposite direction ?

Ans. (*i*) Force is attractive. (*ii*) Force is repulsive.

Q. 2.33. Define an ampere in terms of the force between current carrying conductors. *(I.S.C.E. 1996)*

Ans. *One ampere is that current, which when flowing through each of the two parallel conductors of infinite length and placed in free space at a distance of one metre from each other, produces between them a force of 2×10^{-7} newton per metre of their length.*

Q. 2.34. Does the torque on a planar current loop in magnetic field change, when its shape is changed without changing its geometrical area ?

Ans. The torque on a planar current loop in a magnetic field does not change, when its shape is changed without changing the area of the loop.

Q. 2.35. Estimate the torque on a closed current loop placed in the magnetic field $\vec{B}$. What is the main function of soft iron core used in a moving coil galvanometer ?

Ans. When a closed current loop is suspended in magnetic field, torque on the coil is given by

$$|\vec{\tau}| = |\vec{M} \times \vec{B}| = nBIA \sin\theta,$$

where the letters have their usual meanings.

Q. 2.36. A current carrying loop free to turn is placed in a uniform magnetic field $\vec{B}$. What will be its orientation relative to $\vec{B}$ in the equilibrium state ? *(C.B.S.E. 1990)*

Ans. In equilibrium state, the current carrying loop will orient itself, such that $\vec{B}$ is perpendicular to the plane of the coil. It is because of the fact that in this orientation, the torque on the current loop becomes zero.

Q. 2.37. Under what circumstances, will a current carrying loop not rotate in the magnetic field ?

Ans. If the current carrying loop is placed in a magnetic field, with its plane perpendicular to the field, then it will not rotate.

Q. 2.38. State the principle of moving coil galvanometer. *(P.S.S.C.E. 2001 ; H.S.S.C.E. 2001 ; 1997 S)*

Ans. It is based on the principle that when a current carrying conductor is placed in magnetic field, it experiences a torque.

Q. 2.39. What is the nature of magnetic field in a moving coil galvanometer ? *(C.B.S.E. 1996)*

Ans. It is radial in nature.

Q. 2.40 State two properties of the material of the wire used for suspension of the coil in a moving coil galvanometer. *(C.B.S.E. 2001)*

Ans. 1. Its restoring torque per unit twist should be low.

2. Its tensile strength should be high so that it does not break under the weight of the coil.

Q. 2.41. Define current sensitivity of a galvanometer.

Ans. Refer to section 2.10.

Q. 2.42. Define current sensitivity of a moving coil alvanometer and state its SI unit. (*P.S.S.C.E. 1999 S*)

Ans. For current sensitivity of a moving coil galvanoneter, refer to section 2.10.

The SI unit of current sensitivity is **radian ampere^{-1}.**

Q. 2.43. Give two factors by which the current ensitivity of a moving coil galvanometer can be increased. (*C.B.S.E. 2001*)

Ans. Current sensitivity $= \dfrac{nBA}{k}$,

vhere the letters have their usual meanings. Since n and A annot be increased beyond a limit, current sensitivity may e increased by (*i*) increasing B and (*ii*) decreasing k.

Q. 2.44. Explain voltage sensitivity of a galvanometer. (*P.S.S.C.E. 1991*)

Ans. Refer to section 2.10.

Q. 2.45. Give two factors by which voltage sensitivity of a moving coil galvanometer can be increased. (*C.B.S.E. 2001*)

Ans. Voltage sensitivity $= \dfrac{nBA}{kR}$,

where the letters have their usual meanings. Since n and A can not be increased beyond a limit, voltage sensitivity may be increased by **(*i*)** increasing B, **(*ii*)** decreasing k and **(*iii*)** decreasing R.

Q. 2.46. What is shunt ? State its SI units. (*P.S.S.C.E. 1999 ; H.S.S.C.E. 1996*)

Ans. A small resistance connected in parallel to the coil of the galvanometer is called shunt. Its SI unit is ohm.

Q. 2.47. How will you convert a moving coil galvanometer into an ammeter ? (*H.S.S.C.E. 2002*)

Or

How can a galvanometer be converted into an ammeter ? How will you convert a moving coil galvanometer into an ammeter ? (*C.B.S.E. 2001; P.S.S.C.E. 2000 ; H.P.S.S.C.E. 1998 ; I.S.C.E. 1997*)

Ans. A galvanometer can be converted into an ammeter by connecting a suitable small resistance in parallel to it.

Q. 2.48. Is the resistance of an ammeter greater than or less than that of the galvanometer of which it is formed ?

Ans. The resistance of an ammeter is always less than that of the galvanometer of which it is formed.

Q. 2.49. An ammeter and a milliammeter are converted from the same galvanometer. Out of the two, which current measuring instrument has higher resistance ? (*C.B.S.E. 2002*)

Ans. From the relation,

$$S = \frac{I_g \times G}{I - I_g},$$

it follows that value of S needed to convert the galvanometer into milliammeter is larger than that required to convert into ammeter.

Since the resistance of current measuing instrument,

$$R = \frac{GS}{G+S},$$

it follows that **milliammeter** will possess higher resistance.

Q. 2.50. Why should an ammeter have a low resistance ? (*H.S.S.C.E. 2002*)

Ans. For measuring current in a circuit, an ammeter is connected in series. For the current in the circuit to remain practically unchanged, the resistance of the ammeter should be low.

Q. 2.51. How is an ammeter connected in an electric circuit ?

Ans. An ammeter is connected in series in an electric circuit.

Q. 2.52. How can a galvanometer be converted into voltmeter ? (*H.P.S.S.C.E. 2001 ; C.B.S.E. 2001*)

Ans. A galvanometer can be converted into a voltmeter by connecting a suitable high resistance in series to its coil.

Q. 2.53. Is the resistance of a voltmeter greater than or less than that of the galvanometer of which it is formed ?

Ans. The resistance of a voltmeter is always greater than that of the galvanometer, of which it is formed.

Q. 2.54. What is the resistance of an ideal voltmeter and an ammeter ?

Ans. The resistance of an ideal voltmeter is infinite and that of an ammeter is zero.

Q. 2.55. How is a voltmeter connected in an electric circuit ?

Ans. A voltmeter is connected in parallel in an electric circuit.

Q. 2.56. How does (*i*) an ammeter (*ii*) a voltmeter differ from a galvanometer ? (*P.S.S.C.E. 1998*)

Ans. (*i*) An ammeter is a galvanometer, in which a very small suitable resistance is connected in parallel to it.

(*ii*) A voltmeter is a galvanometer, in which a very high suitable resistance is connected in series to it.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 2.01. Describe qualitatively, the path of a charged particle moving in (*a*) a uniform electrostatic field with initial velocity (*i*) parallel to the field, (*ii*) perpendicular to the field, (*iii*) at an arbitrary angle with the field direction.

Ans. (*i*) The force due to uniform electrostatic field will act along the direction of the field and hence path will be a straight line.

(*ii*) It will follow parabolic path, as the force acts along a direction perpendicular to initial velocity.

(*iii*) It will still follow parabolic path. The velocity of electron may be resolved into two components. The velocity component along the field will not affect its path, while the velocity component perpendicular to the field will make it to follow parabolic path.

Q. 2.02. Why does not a charged particle moving at right angle to the direction of an electric field follow a circular path ?

Ans. A charged particle moving at right angle to the direction of electric field experiences force in the plane of electric field. The force acts at right angle to its path only at the instant the charged particle enters the electric field and with the passage of time, it no longer remains at right angle to the path. Since the force on the charged particle *does not remain always perpendicular to the path,* it does not move along circular path.

Q. 2.03. An electron and a proton are freely situated in an electric field. Will the electric force on them be equal ? Will their acceleration be equal ? Justify your answer. (*P.S.S.C.E. 1999 S*)

Ans. Force on a charged particle having charge e and situated inside an electric field E,

$$F = e\,E$$

Since the magnitude of charge on an electron is same as that on a proton, the electric force on them will be **equal.**

Now, acceleration of electron, $a_1 = \dfrac{e\,E}{m_1}$

and acceleration of proton, $a_2 = \dfrac{e\,E}{m_2}$,

where m_1 and m_2 are respective masses of electron and proton. Since $m_1 < m_2$, the acceleration in the path of **electron** will be greater than that of proton.

Q. 2.04. An electron travelling west to east enters a chamber having a uniform electrostatic field in a north to south direction. Specify the direction in which a uniform magnetic field should be set up to prevent the electron deflecting from its straight line path. (*Text Question*)

Ans. Under the action of electrostatic field, the electron will be deflected towards north (towards positive plate). It will remain undeflected, if force due to magnetic field is towards south. As the velocity $\vec{v}$ of electron is from west to east, the expression for magnetic Lorentz force *i.e.*

$$\vec{F}_m = -e\,(\vec{v} \times \vec{B})$$

or Fleming's left hand rule tells that magnetic field $\vec{B}$ should be applied along vertical and in downward direction.

Q. 2.05. When is the force on a moving charge due to a magnetic field maximum and when is it minimum ?

Ans. We know that $F_m = B\,q\,v \sin\theta$

For force to be maximum, $\sin\theta = 1$ *i.e.* $\theta = 90°$ *i.e.* when the charged particle moves perpendicular to the direction of magnetic field.

For force to be minimum, $\sin\theta = 0$ *i.e.* $\theta = 0°$ *i.e.* when the charged particle moves along the direction of magnetic field.

Q. 2.06. A magnetic field that varies in magnitude from point to point but has a constant direction (east to west) is set up in a chamber. A charged particle enters the chamber and travels undeflected along a straight path with constant speed. What can you say about the initial velocity of the particle ? (*Text Question*)

Ans. The force on a charged particle moving inside magnetic field is given by

$$\vec{F}_m = q\,(\vec{v} \times \vec{B})$$

The force on the charged particle will be zero (will remain undeflected), if $\vec{v} \times \vec{B}$ is equal to zero *i.e.* if initial velocity $\vec{v}$ is either parallel or antiparallel to the magnetic field $\vec{B}$.

Q. 2.07. Is any work done by a magnetic field on a moving charge ?

Ans. Force on a charge q moving inside a magnetic field of strength $\vec{B}$ with velocity is $\vec{v}$ given by

$$\vec{F}_m = q\,(\vec{v} \times \vec{B})$$

Thus, $\vec{F}_m$ is perpendicular to $\vec{v}$ *i.e.* perpendicular to the direction of motion of the charge.

Therefore, work done by magnetic field,

$$W = \vec{F}\,.\,\vec{S} = F\,S \cos 90° = 0$$

i.e. no work is done by magnetic field on a moving charge.

Q. 2.08. Describe qualitatively, the path of a charged particle in a uniform magnetic field with initial velocity (*i*) parallel to the field, (*ii*) perpendicular to the field, (*iii*) at an arbitrary angle with the field direction.

Ans. **(*i*)** No force will act due to uniform magnetic field and hence charged particle will move along straight line.

(*ii*) It will move along a circle in the plane perpendicular to the magnetic field.

(*iii*) It will move along a helical path with its axis parallel to magnetic field.

Q. 2.09. Why does a charged particle moving at right angle to the direction of a magnetic field follow a circular path ?

Ans. When a charged particle moves at right angle to the direction of a magnetic field, it experiences force which *always acts perpendicular to the velocity.* Hence, magnitude of its velocity remains constant and only the direction of the velocity of the charged particle changes. In other words, the force on the charged particle acts as centripetal force and it follows circular path.

Q. 2.10. An electric charge moving in a direction making an angle ϕ ($\neq 90°$) with the direction of magnetic field follows a helical path. Why ?

Ans. When a charge moves with velocity v making an angle ϕ with the direction of magnetic field, the component of velocity $v \sin\phi$ (perpendicular to the magnetic field) makes the charge move along circular path, while the component of velocity $v \cos\phi$ (along the magnetic field) drifts the charge along the direction of the field. As a result, the path of the charge becomes helical.

Q. 2.11. A charged particle is released from rest in a region of steady and uniform electric and magnetic fields, which are parallel to each other. What will be the nature of the path followed by the charged particle ? (*I.I.T. 1999*)

Ans. Under the effect of electric field, the charged particle will move in a straight line along the direction of electric field. The magnetic field will not affect the motion of the charged particle, as it is parallel to the direction of electric field *i.e.* parallel to the direction of motion of the charged particle.

Q. 2.12. The energy of a charged particle moving in a uniform magnetic field does not change. Why ? Explain. (*C.B.S.E. 2002 ; P.S.S.C.E. 2001*)

Ans. The force on a charged particle moving in a uniform nagnetic field always acts in a direction perpendicular to the lirection of motion of the charge. As work done by magnetic ield on the charge is zero, the energy of the charged particle loes not change.

Q. 2.13. A beam of α-particles and of protons, of the ame velocity v, enters a uniform magnetic field at right ngles to the field lines. The particles describe circular aths. Calculate the ratio of the two paths.

(C.B.S.E. 2001 S)

Ans. Let m_1 and q_1 be mass and charge on α-particle. Let $_1$ be radius of the circular path described by the α-particle, vhen it moves in a uniform magnetic field B with a veloity v. Then,

$$B q_1 v = \frac{m_1 v^2}{r_1} \quad \text{or} \quad r_1 = \frac{m_1 v}{B q_1}$$

Let m_2 and q_2 be mass and charge on proton. Then, adius of the circular path described by the proton, when moving with same velocity v in magnetic field B, is given by

$$r_2 = \frac{m_2 v}{B q_2}$$

$$\therefore \quad \frac{r_1}{r_2} = \frac{m_1 v}{B q_1} \times \frac{B q_2}{m_2 v} = \frac{m_1 / m_2}{q_1 / q_2} = \frac{4}{2} = 2$$

Q. 2.14. An electron beam passes through a region of crossed electric and magnetic fields of intensities E and B respectively. For what value of electron speed will the beam remain undeflected ? *(C.B.S.E. 2001 S)*

Ans. Let v be the electron speed, for which beam remains undeflected while crossing through crossed electric and magnetic fields. For the beam to remain undeflected, the force on an electron due to two fields should be equal and opposite

i.e. $\quad B e v = e E \quad$ or $\quad v = \dfrac{E}{B}$

Q. 2.15. A point charge + q is moving with speed v perpendicular to a magnetic field B as shown in Fig. 2.30. Explain, what should be the magnitude and direction of the applied electric field, so that net force acting on the charge is zero. *(C.B.S.E. Sample Q. Paper)*

Ans. The magnetic field as shown in Fig. 2.29 is perpendicular to the plane of paper and in inward direction.

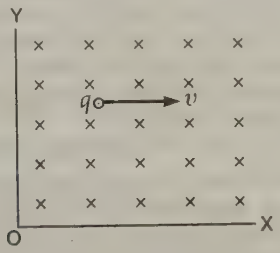

Fig. 2.29

The force on the charge due to magnetic field is given by

$$\vec{F} = q(\vec{v} \times \vec{B})$$

i.e. the magnitude of the force will be equal to B q v and the force will be along OY. If E is the strength of electric field, then force on charge q due to electric field will be q E. So that the net force on charge is zero, q E should be equal and opposite to B q v *i.e.*

$$q E = B q v$$

or $\quad E = B v$

The direction of electric field will be along **YO.**

Q. 2.16. `Cyclotron is not suitable for accelerating electrons.' Explain the reason.

(P.S.S.C.E. 2002 ; H.S.S.C.E. 1997)

Or

Why is a cyclotron not suitable for accelerating electrons ? *(P.S.S.C.E. 1996 S)*

Ans. Electrons have very small mass. Even a small increase in the energy of the electron imparts a very high speed to it. Due to the high speed, the electrons go quickly out of step with the oscillating electric field. Also, the fast relativistic variation in mass of electrons poses a serious problem, when cyclotron is used to accelerated electrons.

Q. 2.17. What is the force that a conductor $\vec{dl}$ carrying a current I experiences, when placed in a magnetic field $\vec{B}$? What is the direction of the force ?

(H.P.S.S.C.E. 1996 ; C.B.S.E. 1990)

Ans. The force is given by

$$\vec{dF} = I\, \vec{dl} \times \vec{B}$$

The direction of force is given by the cross-product $I\, \vec{dl} \times \vec{B}$. It can also be found by using Fleming's left hand rule. For Fleming's left hand rule, refer to section 2.07.

Q. 2.18. In the Fig. 2.30, the straight wire AB is fixed, while the loop is free to move under the influence of the electric currents flowing in them. In which direction does the loop begin to move ? Give reason for your answer.

(C.B.S.E. 1999, 1997)

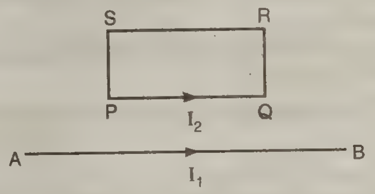

Fig. 2.30

Ans. The currents in arm PQ and wire AB are in same direction and hence wire will attract the arm PQ with a force, say F_1. On the other hand, the arm RS of the loop will experience a force of repulsion, say F_2. Since the arm PQ is closer to wire AB, $F_1 > F_2$ *i.e.* the loop will move towards the wire.

Q. 2.19. Write the relation for force between two parallel wires carrying current and hence define unit of current.

(P.S.S.C.E. 1996 S)

Ans. Force between two parallel wires carrying current is given by

$$F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r},$$

where the letters have their usual meanings.

For definition of unit of current *i.e.* ampere, refer to VSQ 2.33.

Q. 2.20. Why do the two parallel conductors carrying current exert force on each other ?

Ans. The current flows in a conductor due to the motion of electrons through it. When a current carrying conductor is placed inside a magnetic field, the electrons moving inside the conductor experience force due to the magnetic field in a direction perpendicular to the length of the conductor. As the electrons are confined to the conductor, the force on the electrons shows its effect as the force on the conductor.

Q. 2.21. Two parallel conducting wires carrying electric current in the same direction attract each other. Explain, why. *(P.S.S.C.E. 2001)*

Ans. The current through one conducting wire produces magnetic field and the other parallel current carrying wire experiences force due to this magnetic field. The application of Biot Savart's law tells that when the current in the two wires is in same direction, the two wires attract each other.

Q. 2.22. Why do two straight parallel metallic wires carrying current in the opposite directions repel each other. *(P.S.S.C.E. 2001 ; H.S.S.C.E. 1999)*

Ans. The current through one metallic wire produces magnetic field and the other parallel current carrying metallic wire experiences force due to this magnetic field. The application of Biot Savart's law tells that when currents flow through the two conductors in opposite directions, one parallel wires repels the other.

Q. 2.23. Why should a solenoid tend to contract, when a current passes through it ?

Ans. When current flows through a solenoid, the currents in the various turns of the solenoid are parallel and in the same direction. Since the currents flowing through parallel wires in the same direction lead to force of attraction between them, the turns of the solenoid will also attract each other and as a result, the solenoid tends to contract.

Q. 2.24. A rectangular loop of area A, having N turns and carrying a current of I ampere is held in a uniform magnetic field B.

(*i*) Write down the expression for the maximum torque experienced by the loop.

(*ii*) In which orientation, will the loop be in stable equilibrium ? *(C.B.S.E. 1998 S)*

Ans. (*i*) $\tau_{max} = \text{N B I A}$

(*ii*) When the plane of the coil becomes parallel to the direction of magnetic field, it will experience no torque and hence it will be in stable equilibrium.

Q. 2.25. A current carrying circular loop is located in a uniform external magnetic field. If the loop is free to turn, what is its orientation of stable equilibrium ? Show that in this orientation, the flux of the total field (external field and the field produced by the loop) is maximum. *(Text Question)*

Ans. The stable equilibrium position will be that in which vector $\vec{A}$ representing the area of the circular loop and $\vec{B}$ are parallel. As both the fields (applied field and the field produced by current loop) are in same direction, the flux of the total field is maximum in this orientation of the loop.

Q. 2.26. A small coil carrying a current is placed in a uniform magnetic field. How does the coil tend to orient itself relative to the magnetic field ?

Ans. The torque acting on a coil is given by

$$\tau = n\,\text{B I A} \cos\alpha,$$

where α is the angle between the plane of the coil the and the direction of magnetic field. When $\alpha = 90°$,then

$$\tau = 0$$

The coil tries to orient itself in this position. Thus, in equilibrium, the coil will acquire a position, such that its plane makes an angle of 90°with the direction of magnetic field.

Q. 2.27. The torque on a planar current loop depends upon its area and is independent of the shape of the loop of the planar loop. Explain.

Ans. A planar loop of any shape can be divided into a large number of rectangular strips as shown in Fig. 2.31.

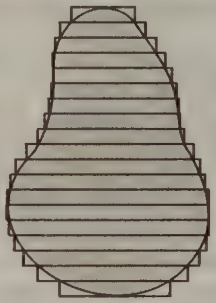

Fig. 2.31

Each rectangular strip is acted upon by a small torque. In the horizontal arms of any two adjacent rectangular strips, the current flows in opposite directions and hence net force on the horizontal arms of the rectangular strips is zero. The vertical arms of the strips will coincide more and more with the boundary of the planar loop, as the number of strips into which the planar loop is divided, is increased. Therefore, in the limiting case, magnetic moment $(\text{I}\vec{\text{A}})$ of the planar loop is equal to current times the total area of the rectangular strips *i.e.* the area of the planar loop and hence torque $\vec{\tau}\,(= \text{I}\,\vec{\text{A}} \times \vec{\text{B}})$ depends upon its area and is independent of the shape of the loop.

Q. 2.28. Explain, why earth's magnetic field does not affect the working of a moving coil galvanometer.

Ans. The field magnet used in a moving coil galvanometer is very strong. The earth's magnetic field is quite weak as compared to the magnetic field produced by the field magnet. Practically, the coil rotates under the effect of the strong magnetic field due to the field magnet and the weak magnetic field due to the earth does not affect the working of the moving coil galvanometer.

Q. 2.29. What is the importance of radial magnetic field in a moving coil galvanometer ?

(C.B.S.E. 2001 ; P.S.S.C.E. 2001, 2000 ; H.P.S.S.C.E. 1995)

Ans. The coil of the galvanometer experiences torque due to the action of magnetic field produced by the field magnet. In case the field magnet has flat poles, the torque on the coil decreases as it rotates from its equilibrium position (when plane of the coil is parallel to the magnetic field). It is because, in the new position, the plane of the coil is not parallel to the magnetic field. Moreover, as such, the deflection in the coil is not directly proportional to the current passed through the coil.

When the magnetic field is made radial by using a eld magnet with concave poles, the plane of the coil always mains parallel to the direction of the magnetic field. Due this, the galvanometer scale becomes linear.

Q. 2.30. What is the main function of soft iron core used a moving coil galvanometer ?

Ans. When a soft iron core is used, the magnetic field es tend to crowd through the core. It is because, soft iron re is ferromagnetic in nature. As a result, the strength of the agnetic field due to the field magnet increases, which in turn creases the sensitivity of the galvanometer.

Q. 2.31. Explain the action of a shunt.

(Pre-degree Kerala, 1992)

Ans. A shunt is a small resistance connected in parallel a galvanometer. The resistance of a galvanometer is small nd if the whole of the current in an electric circuit passes rough it, it may get damaged. The shunt allows only a small art of the current to flow through the galvanometer by acting a by pass to the major part of the current.

Q. 2.32. It is desired to pass only 5% of the current rough a galvanometer of resistance 95 Ω. What shunt esistance should be connected across it ?

Ans. Here, $G = 95\ \text{W}\ ; I_g = \frac{5\,I}{100}$ or $I = 20\,I_g$

Now, $S = \frac{I_g\,G}{I - I_g} = \frac{I_g \times 95}{20\,I_g - I_g} = 5\,\Omega$

Q. 2.33. A galvanometer has a resistance of 50 ohm. A esistance of 5 ohm is connected across its terminals. What art of total current will flow through the galvanometer ?

(H.S.C.C.E. 2001, 1992)

Ans. We know, $S = \frac{I_g\,G}{I - I_g}$ or $\frac{I_g}{I} = \frac{S}{G + S}$

Here $G = 50\,\Omega$ and $S = 5\,\Omega$

$\therefore\quad \frac{I_g}{I} = \frac{5}{50 + 5} = \frac{1}{11}$

Q. 2.34. A galvanometer coil has a resistance of 15 Ω nd the meter shows full scale deflection for a current of 4 nA. How will you convert the meter into an ammeter of ange 0 to 6 A ? *(Text Question)*

Ans. Here, $G = 15\,\Omega;\ I_g = 4\text{ mA} = 4 \times 10^{-3}\text{ A}\ ; I = 6\text{ A}$

To convert a galvanometer into an ammeter, a small esistance S has to be connected in parallel to the coil of the alvanometer. Then,

$$S = \frac{I_g\,G}{I - I_g} = \frac{4 \times 10^{-3} \times 15}{6 - 4 \times 10^{-3}} = 0{\cdot}01\,\Omega$$

Q. 2.35. A galvanometer has a resistance of 100 ohm. resistance of one ohm is connected across its terminals. What part of the total current flows through the galvano-neter ? Draw the necessary circuit diagram.

(P.S.S.C.E. 1996 S)

Ans. Here, $G = 100\,\Omega\ ; S = 1\,\Omega$

Let I be the total current in the circuit and the part I_g flow hrough the galvanometer as shown in Fig.2.32.

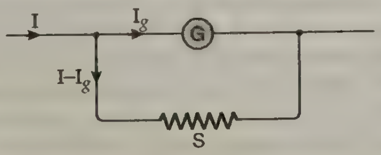

Fig. 2.32

Then $I_g \times G = (I - I_g) \times S$

or $I_g\,(G + S) = I\,S$

or $\frac{I_g}{I} = \frac{S}{G + S} = \frac{1}{100 + 1} = \frac{1}{101}$

Q. 2.36. Why an ammeter should have as low a resistance as possible ? Explain.

Ans. An ammeter is connected in series in an electric circuit to measure the current. In case the resistance of ammeter is not low, the current in the circuit will decrease on connecting it in the circuit. For this reason, the ammeter should have as low a resistance as possible.

Q. 2.37. When an ammeter is put in a circuit, does it read slightly less or more than the actual current in the original circuit ? Explain.

Ans. Yes, when an ammeter is connected in a circuit, it reads slightly less than the actual current in the circuit. It is because, an ammeter has a small resistance and when it is connected in the circuit, it decreases the current by a small amount.

Q. 2.38. A galvanometer gives full scale deflection with the current I_g. Can it be converted into an ammeter of range $I < I_g$?

Ans. The required value of shunt is given by

$$S = \frac{I_g \times G}{I - I_g}$$

For $I < I_g$, the above formula gives negative value for S. Hence, it cannot be converted into an ammeter of range $I < I_g$.

Q. 2.39. Can we increase/decrease the range of a given ammeter ?

Ans. As discussed above, the range of given ammeter cannot be decreased. It is because, S can not be negative.

However, the range of an ammeter can be increased by selecting a proper shunt. In the formula for S (in last question), I_g will represent the present range of the ammeter.

Q. 2.40. How does a voltmeter differ from ammeter ?

(P.S.S.C.E. 1999)

Or

Compare a voltmeter and an ammeter.

(P.S.S.C.E. 1998 S)

Ans. 1. An ammeter is a galvanometer to which a small resistance is connected in parallel, while a voltmeter is a galvanometer to which a high resistance is connected in series.

2. An ammeter is a low resistance instrument, while a voltmeter is a high resistance instrument.

3. An ammeter is always connected in series, while a voltmeter is connected in parallel to the part of the circuit across which potential difference is to measured.

4. An ammeter is used to measure current, while a voltmeter is used to measure potential difference in a circuit.

Q. 2.41. How can a moving coil galvanometer be converted into a voltmeter ? *(C.B.S.E. 1991)*

Ans. A moving coil galvanometer can be converted into a voltmeter by connecting a suitable high resistance R in series with its coil. The value of R is given by

$$R = \frac{V}{I_g} - G,$$

where I_g, G and V have their usual meanings.

Q. 2.42. A voltmeter of resistance R is to be used to measure a voltage 100 times as large as it can measure without an additional resistance in series. How large a resistance is to be used in series with the meter ?

Ans. Suppose that a voltmeter of resistance R can measure potential difference upto V. Obviously, when potential difference V is applied, the deflection in the voltmeter is maximum *i.e.*

$$I_g = \frac{V}{R}$$

So that the voltmeter can measure potential difference as large as 100 times V *i.e.* 100 V, suppose that the value of the resistance R′ to be connected in series with the meter is R′. Then,

$$R' = \frac{(100\ V)}{I_g} - R = \frac{100\ V}{V/R} - R = 99\ R$$

Q. 2.43. A galvanometer coil has a resistance of 12 Ω and the meter shows full scale deflection for a current of 3 mA. How will you convert the meter into a voltmeter of range 0 to 18 V ? *(Text Question)*

Ans. Here, $G = 12\ \Omega$; $I_g = 3\ mA = 3 \times 10^{-3}\ A$; $V = 18$ volt

To convert galvanometer into voltmeter, a large resistance R has to be connected in series to the coil of the galvanometer. Then,

$$R = \frac{V}{I_g} - G = \frac{18}{3 \times 10^{-3}} - 12 = 5988\ \Omega$$

Q. 2.44. A good quality voltmeter should have a large istance. Explain.

Ans. A voltmeter is connected in parallel to the conductor, across which the potential difference is to be measured. Obviously, the potential difference across the conductor should not change on connecting the voltmeter across the conductor. It will be so, only if the voltmeter draws a negligible current *i.e.* if its resistance is very large.

Q. 2.46. Draw a circuit, showing how an ammeter and a voltmeter can be connected to a resistor to measure the current and voltage at a given instant. *(I.S.C.E. 1996)*

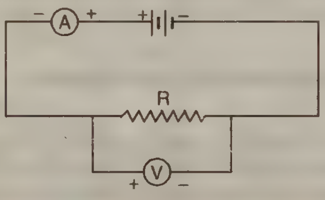

Fig. 2.33

Ans. In order to measure current through the resistor and to measure voltage across it, ammeter (A) and voltmete are connected as shown in Fig. 2.34.

Q. 2.45. When a voltmeter is put across a part of th circuit, does it read slightly less or more than the origina voltage drop across that part ? Explain.

Ans. When a voltmeter is put across a part of the circui it reads slightly less than the original potential drop acros that part. It is because, the voltmeter draws some curren form the part of the circuit across which it is connected an as a result, the potential drop across that part decreases.

Q. 2.47. Why is an ammeter connected in series, whil the voltmeter is connected in parallel with the rest of th circuit ? *(H.S.S.C.E. 2000*

Ans. An ammeter is a low resistance instrument, whil a voltmeter is a high resistance instrument.

When an ammeter is connected in series, the resistanc of the circuit remains practically the same. In case it i connected in parallel, most of the current will flow throug it and the current in the main circuit will decrease.

When a voltmeter is connected in parallel with the res of the circuit, only a very small amount of current will flov through the voltmeter and hence current in the circuit remain the same. In case, the voltmeter is connected in series, th current in the circuit will decrease appreciably due to hig resistance of the voltmeter.

Q. 2.48. Can we increase/decrease the range of a give voltmeter ?

Ans. The range of a given voltmeter can both b increased and decreased.

We know that for converting a galvanometer o resistance G into a voltmeter of range V, a high resistance given by

$$R = \frac{V}{I_g} - G$$

has to be connected in series to the coil of the galvanomete

In order to increase the range of the voltmeter, R has t be increased. It can be done by putting a suitable resistanc in series with the resistance R.

On the other hand, to decrease the range of th voltmeter, R has to be decreased. It can be done by putting suitable resistance in parallel with the resistance R.

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 2.01. A charged particle enters an environment of a strong and non-uniform magnetic field varying from point to point both in magnitude and direction and comes out of it following a complicated trajectory. Would its final speed equal to initial speed, if it suffered no collisions with the environment ? *(Text Question)*

Ans. The magnetic field exerts force on the charged particle always perpendicular to its motion and hence does no work. Therefore, charged particle will have its final speed equal to its initial speed, provided it suffered no collision with the environment.

Q. 2.02. A cloud chamber photograph shows a pair of circular tracks emerging from a common point. The tracks have similar density of droplets, but curve i opposite directions in a plane normal to the magnetic fiel maintained in the chamber. If one of the ionizing particle is established to be an electron, guess the high energy even that took place at the common point of the track. *(Text Question*

Ans. The similarity of the two paths shows that the othe charged particle has same mass and same magnitude o charge as that of electron. As the tracks are curved in opposit directions, the nature of charge on the other particle i opposite to that of electron. This other particle is calle positron. Thus, at the common point of the track, the hig energy event that took place is conversion of a γ-ray photo into electron-positron pair.

Q. 2.03. A similar event as described in conceptual SAQ 2.02 photographed in a liquid hydrogen bubble mber shows spiral tracks instead of circular tracks. lain, why ? *(Text Question)*

Ans. A charged particle produces much more ionization liquid than in a gas. Therefore, in liquid hydrogen bubble mber, the charged particles produce ionization and gressively lose energy due to collisions encountered with environment. Since, the radius of circular path followed charged particle inside magnetic field is proportional to peed, the radius of circular path also goes on decreasing gressively. Hence, the charged particle follows spiral path.

Q. 2.04. A soft spiral spring hangs freely with its upper end fixed to a rigid support. The lower end of spring is immersed in a cup of mercury. The spring the cup are connected to a d.c. source as shown in 2.34. What will happen to the spring after the switch closed ?

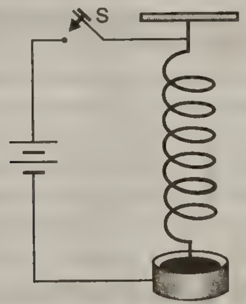

Fig. 2.34

Ans. When the switch S is closed, the current flows ough each coil of the spring in the same direction. As such, coils of the spring will attract each other and the spring l be compressed. On being compressed, the lower end of spring will get out of the mercury cup and the current will interrupted. As it happens so, the coils of the spring will se to attract each other and the spring will then straighten lf out. As soon as the lower end of the spring enters the rcury cup, the current will begin to flow through the spring l the entire process will be repeated.

Q. 2.05. A beam of electrons is moving with a velocity of 3×10^6 m s^{-1} and carries a current of 1 μA.

(a) How many electrons per second pass a given int ?

(b) How many electrons are in 1 m of the beam ?

(c) What is the total force on all the electrons in 1 m of beam, if it passes through a field of 0·1 N A^{-1} m^{-1}?

(d) What is the force on a single electron, if the ctrons experience the same force ?

Ans. Here, $v = 3 \times 10^6 \text{ m s}^{-1}$; $I = 1\ \mu A = 10^{-6}$ A

(a) The number of electrons passing a given point per cond,

$$n = \frac{I}{e} = \frac{10^{-6}}{1 \cdot 6 \times 10^{-19}} = \mathbf{6 \cdot 25 \times 10^{12}}$$

(b) Since electrons traverse a distance of 3×10^6 m in 1 s, number of electrons in 1 m of the beam

$$= \frac{6 \cdot 25 \times 10^{12}}{3 \times 10^6} = \mathbf{2 \cdot 08 \times 10^6\ m^{-1}}$$

(c) Force on 1 m beam of electrons,

$$F = B\,I\,l = 0{\cdot}1 \times 10^{-6} \times 1 = \mathbf{10^{-7}\ N}$$

(d) Since 1 m contains $2{\cdot}08 \times 10^6$ electrons, force on one electron,

$$f = \frac{F}{2 \cdot 08 \times 10^6} = \frac{10^{-7}}{2 \cdot 08 \times 10^6} = \mathbf{4 \cdot 81 \times 10^{-14}\ N}$$

Q. 2.06. A straight conductor carrying current I_1 is passed along the axis of a circular conductor carrying current I_2 [Fig. 2.35]. With what force are the currents interacting ?

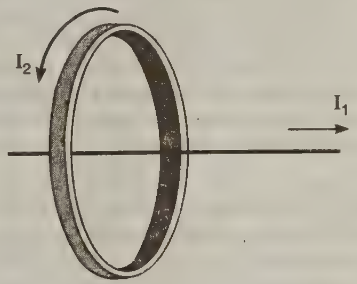

Fig. 2.35

Ans. The lines of force of the magnetic field B_2 produced by the current I_2 flowing through the circular conductor will be along the length of the straight conductor carrying current I_1. As the angle between magnetic field B_2 and the current I_1 is 0°, the straight conductor will not experience any force due to the current through circular conductor.

The lines of force of the magnetic field B_1 produced by the current I_1 flowing through the straight conductor are circular. The angle between the magnetic field B_1 and all the elements of circular conductor with current I_2 is 0°. Therefore, the current carrying circular conductor will also not experience any force due to the magnetic field produced by the straight conductor.

Thus, currents I_1 and I_2 are interacting with **no force.**

Q. 2.07. A rubber band is covered with a conducting coating and current is passed through it in the direction as shown in Fig. 2.36.

(a) What happens, when it is placed in the magnetic field $\vec{B}$ shown in the figure ?

(b) What happens, if the current is reversed in the rubber band ?

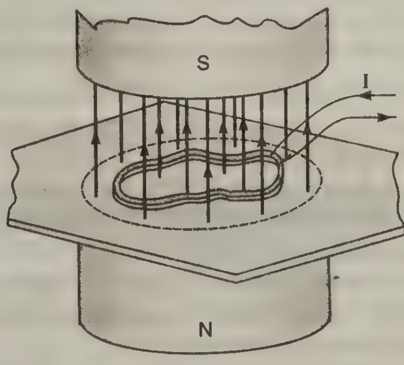

Fig. 2.36

Ans. (*a*) From Fleming's left hand rule, it follows that the force on each portion of the rubber band acts in the plane of the rubber band but is directed outwards. If we consider that the rubber band is made of a large number of small straight portions and since the current is the same in every portion of the rubber band, the force on each small portion is equal in magnitude and directed outwards. By symmetry, outward forces move the rubber band until it assumes a circular shape. The stable shape of the rubber band occurs, when the magnetic force on each small portion is balanced by the elastic forces at each end of that portion.

(*b*) When the direction of the current is reversed, the force on each small portion is now inward instead of outward. The rubber band collapses inward toward the centre and then continues outward away from the centre, until it again acquires a circular shape, each portion of which has come from a position diametrically opposite.

Q. 2.08. A loop of irregular shape carrying current is located in an external magnetic field. If the wire is flexible, why does it change to a circular shape ?

(*P.S.S.C.E. 1996 ; Text Question*)

Ans. It will assume circular shape with its plane normal to the field in order to maximise the magnetic flux through it. The reason is that for a given perimeter, of all the geometrical shapes, a circle has maximum area.

For details, refer to conceptual SAQ. 2.07.

Q. 2.09. The magnetic field $\vec{B}$ inside a long solenoid is uniform and parallel to the axis of the solenoid and is equal to 10^{-2} N A m^{-1}. A wire ABCD carrying a current of 1 A and supported on a light rectangular ebonite strip is placed inside the solenoid and parallel to its axis [Fig. 2.37].

(*a*) What is the force on portion AB (or CD) of the wire, if its length is 0 · 1m ?

(*b*) What is the force on portion BC of the wire, if its length is 0·02 m ?

(*c*) How much mass M should be attached to the left end of the ebonite strip to keep it form tilting ? Assume that strip forms an equal-arm balance.

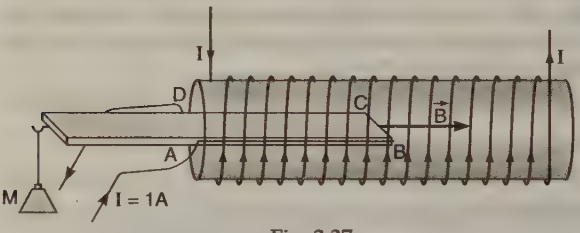

Fig. 2.37

Ans. (*a*) The current in the portion AB (or CD) is parallel to the magnetic field produced by the solenoid along its axis. Since there is no component of the magnetic field $\vec{B}$ perpendicular to the current in AB (or CD), the force on such a portion of the wire is **zero.**

(*b*) The current in portion CD is perpendicular to the direction of the magnetic field $\vec{B}$. The magnitude of force on portion CD is given by

$$F = B\,I\,l = 10^{-2} \times 1 \times 0{\cdot}02 = \mathbf{2 \times 10^{-4}\ N}$$

(*c*) The strip will not tilt, if a mass M is attached to its left end. Therefore, in equilibrium,

$$F = Mg \qquad \text{or} \qquad Mg = 2 \times 10^{-4}$$

$$\text{or} \qquad M = \frac{2\times10^{-4}}{g} = \frac{2\times10^{-4}}{9{\cdot}8} = \mathbf{2{\cdot}04\times10^{-5}\ kg}$$

Q. 2.10. The two parallel circular loops of wire show in Fig. 2.38 each have a radius R = 20 cm and ar separated by a distance *a* = 0·5 cm. The bottom loop is hel fixed and the top loop hangs from one end of the arm of a equal-arm balance. Since *a* is much smaller than R, th magnetic field produced by one loop at the other i practically the same as if both were long straight wires.

(*a*) If the current in each loop is 20 A, how big is th force of attraction of one loop for the other ?

(*b*) How much additional mass *m* must be added to th right-hand pan of the balance to keep the loops separate by 0·5 cm, when the currents are turned on ?

Ans. Here, radius of each loop, R = 20 cm = 0·2 m ; distance between the loops, a = 0·5 cm = 5 × 10^{-3} m

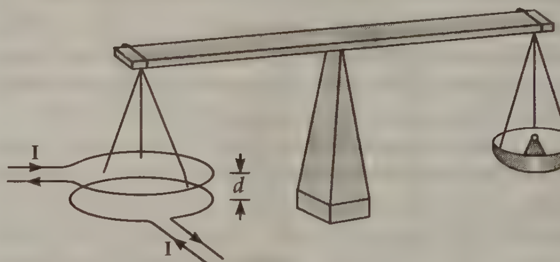

Fig. 2.38

(*a*) Assuming the magnetic field produced by the lowe loop to be practically the same as due to a straight conducto magnetic field produced by lower loop at the top loop,

$$B = \frac{\mu_0}{4\pi}\cdot\frac{2I}{a} = \frac{10^{-7}\times2\times20}{5\times10^{-3}} = 8\times10^{-4}\ \text{T}$$

Again considering the top loop as a straight conducto force on the top loop due to the lower loop,

$$F = B\,I\ (\text{circumference of the top loop})$$
$$= B\,I \times 2\pi R = 8\times10^{-4}\times20\times2\pi\times0{\cdot}2$$
$$= \mathbf{2\times10^{-2}\ N}$$

(*b*) The mass *m* added to the right-pan of the balance i given by

$$F = m\,g$$

$$\text{or} \qquad m = \frac{F}{g} = \frac{2\times10^{-2}}{9{\cdot}8} = \mathbf{2{\cdot}04\times10^{-3}\ kg}$$

Q. 2.11. Currents are passed through two free straigh conductors AB and CD arranged at right angles a shown in Fig. 2.39. How will the interaction of the magneti fields of the currents change the position of the conductor relative to each other ?

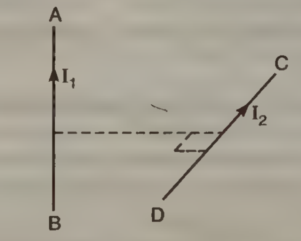

Fig. 2.39

Ans. Fig. 2.40 shows the part of magnetic field produced

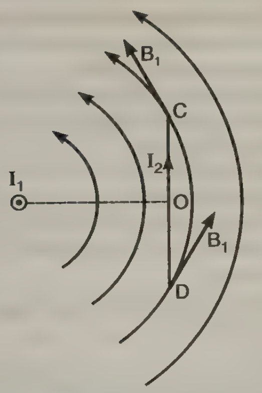

Fig. 2.40

conductor AB carrying current I_1. Suppose that the rength of magnetic field due to the current carrying nductor AB at the ends C and D is B_1. Force on the end C the conductor CD acts perpendicular to the plane of paper lane containing conductor CD and the magnetic field B_1) d in outward direction, while an equal force acts on end perpendicular to the plane of paper and in inward rection. Under the action of these forces, the conductor CD ill turn and the two conductors will become parallel to each her. As they do so, currents in the two conductors flow in me direction and the two will get mutually attracted wards each other.

Q. 2.12. An infinitely long current caryimg straight conductor AB has near it a uniform straight conductor D of finite length and capable of moving freely. Initially, e whole of the conductor CD lies on one side of AB and a plane passing through AB [Fig. 2.41]. What will happen the conductor CD, if current is passed through it in the irection from C to D ?

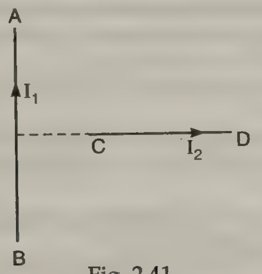

Fig. 2.41

Ans. The strength of the magnetic field produced due o current carrying conductor AB is not uniform over the ength of the conductor CD. The strength of the magnetic field t the end C will be greater than that at the end D. Therefore, ifferent elements of the current carrying conductor CD will experience different amounts of force due to the magnetic field produced by the current carrying conductor AB. Larger forces will act on the elements adjoining the end C than on the identical elements adjoining the end D. The resultant F of the forces on all the elements of the conductor CD will lie to the left of its centre of gravity G [Fig. 2.42].

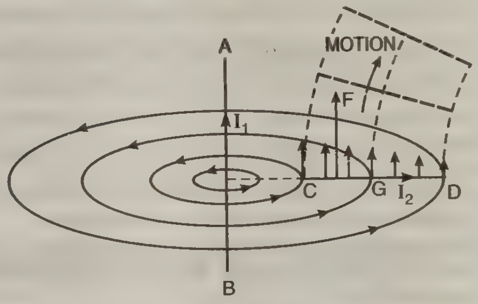

Fig. 2.42

As the resultant force F does not act at the centre of gravity of the conductor CD, it will move up and turning at the same time, till it also becomes parallel to the conductor AB. As the current through the two conductors flow in opposite directions, the conductor CD will get repelled away by the conductor AB.

Q. 2.13. Two parallel wires carrying currents in same direction attract each other, while two beams of electrons travelling in the same direction repel each other. Explain, why. *(P.S.S.C.E. 1995)*

Ans. We know that when current flows through two parallel wires in the same direction, the force F_m experienced by one wire is due to the magnetic field produced by the other wire and is attractive in nature.

In case of two beams of electrons moving in the same direction, in addition to the force F_m, another force F_e (repulsive in nature) also acts on them. Since $\frac{F_m}{F_e} \approx 10^{-27}$, electrons appear to experience a strong repulsive force only.

Q. 2.14. A current carrying circular loop lies on a smooth horizontal plane. Can a uniform magnetic field be set up in such a manner that the loop turns around itself (*i.e.* turns about the vertical axis) ? *(Text Question)*

Ans. The magnetic field cannot be set up to turn the loop around itself. We know that

$$\vec{\tau} = \vec{M} \times \vec{B} = I\,\vec{A} \times \vec{B},$$

where $\vec{A}$ is vector representing area of the circular loop.

For turning the loop around itself, $\vec{\tau}$ should be along vertical. Since area vector $\vec{A}$ acts perpendicular to the plane of loop *i.e.* along vertical, $\vec{\tau}$ cannot act along vertical.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. Show that the path of a charged particle moving inside the electric field $\vec{E}$ is parabolic in nature. *(H.P.S.S.C.E. 1999 S)*
2. Show that the trajectory of an electron moving in a direction perpendicular to the electric field is parabolic. *(H.P.S.S.C.E. 1997)*

3. A stream of electrons travelling with speed v m s^{-1} at right angles to a uniform magnetic field E, is deflected in a circular path of radius r. Prove that $\frac{e}{m} = \frac{v^2}{r\,E}$. *(C.B.S.E. 2002)*
4. Write an expression for the force $\vec{F}$ acting on a charge q moving with a velocity $\vec{v}$ in region, where magnetic induction $\vec{B}$ is uniform. How does the speed change, as the charge moves ? Under what circumstances, the force $\vec{F}$ shall be zero ? *(I.S.C.E. 1996)*
5. Write the expression for the force on a charge q moving with a velocity $\vec{v}$ in a magnetic field $\vec{B}$. Discuss the cases, when the force is maximum and minimum.
6. Discuss the circular motion of a charged particle under the action of a magnetic field. Hence, find expression for its time period.
7. A charge q moving in a straight line is accelerated by a potential difference V. It enters a uniform magnetic field B perpendicular to its path. Deduce in terms of V an expression for the radius of the circular path in which it travels. *(C.B.S.E. 2000)*
8. An electron beam of velocity v moving in the plane of paper enters a region of uniform magnetic field, which is perpendicular to the plane of the paper and travels in a circular path. (*a*) Deduce an expression for the time period of the electron. (*b*) Does the kinetic energy of electron change during this time ? Give reason. *(C.B.S.E. 1998 S)*
9. A particle with charge q moving with a velocity v in the plane of the paper enters a uniform magnetic field B, acting perpendicular to the plane of the paper. Deduce an expression for the time period of the charge, as it moves in a circular path in the field. Why does the kinetic energy of the charge not change, while moving in the magnetic field ? *(C.B.S.E. 2001)*
10. A charged particle of mass m, charge q, moving at uniform velocity v, enters a uniform magnetic field B acting normal to the plane of the paper. Deduce expression for the (*i*) radius of the circular path in which it travels, (*ii*) kinetic energy of the particle (assuming $v << c$). Why does the kinetic energy of the charge not change, when moving through the magnetic field ? *(C.B.S.E. 2001)*
11. Discuss the motion of a charged particle moving in a direction making angle θ with the direction of the magnetic field.
12. Explain the construction and theory of a cyclotron. *(P.S.S.C.E. 2000)*
13. Find the frequency of electric field to be applied between dees of a cyclotron to accelerate charged particles by it. *(H.S.S.C.E. 1994 ; C.B.S.E. 1994)*
14. Show that the frequency of a charge circulating at right angle to a uniform magnetic field does not depend upon the speed of the charge.
15. Explain, by drawing a labelled diagram, how a positively charged particle is accelerated in a cyclotron. *(C.B.S.E. 1994)*
16. Derive an expression for the force experienced by a curre
    carrying conductor placed in a magnetic field.
    (P.S.S.C.E. 1999 S, 1996 ; H.S.S.C.E. 199
17. Define the SI unit of magnetic field. Deduce an expressio
    for the force F on a conductor of length l carrying a curre
    I in a uniform magnetic field B. *(C.B.S.E. 200*
18. Derive the relation for the force per unit length betwe
    two infinitely long parallel straight wires carrying curren
    Hence, define one ampere. *(H.S.S.C.E. 200*
19. Derive a mathematical expression for the force per ur
    length acting on each of the two straight parallel metal
    conductors carrying current in the same direction and ke
    near each other. Why do such current carrying conducto
    attract each other ? *(C.B.S.E. 199*
20. Find the magnitude and direction of the force between tv
    parallel conducting wires carrying current and hen
    define ampere. *(H.S.S.C.E. 1999 S ; P.S.S.C.E. 1999, 199*
21. Find the force between the two long parallel wires carryi
    current in the same direction.
    (H.S.S.C.E. 2000 ; H.P.S.S.C.E. 200
22. Two long thin straight parallel wires, each carrying
    current I in the same direction, are separated by a distan
    d. Indicate the direction of the force between them. Wri
    down the expression for the magnitude of force per ur
    length of the wire and hence define an ampere.
    (C.B.S.E. 1999
23. Derive a formula for the force between two parall
    straight conductors carrying current in opposi
    directions and write the nature of the force. Hence, defi
    an ampere. *(C.B.S.E. 199*
24. Derive an expression for the torque acting on a curre
    carrying loop suspended in a uniform magnetic field.
    (P.S.S.C.E. 200
25. Obtain an expression for torque acting on a rectangul
    current loop, when placed inclined at an angle θ with t
    direction of magnetic field B. *(H.S.S.C.E. 199*
26. Derive an expression for the torque on a rectangular c
    of area A, carrying a current I and placed in a unifor
    magnetic field B. The angle between the direction of B a
    vector perpendicular to the plane of the coil is θ.
    (H.S.S.C.E. 2002 ; C.B.S.E. 199
27. State the principle of a moving coil galvanometer. Show th
    the current passing through the coil is directly proportion
    to the deflection of the coil. *(H.S.S.C.E. 200*
28. What is a galvanometer ? How can it be converted into
    ammeter ? *(H.P.S.S.C.E. 200*
29. What is a galvanometer ? With the help of a schematic di
    gram, explain how it can be converted into an ammete
    (H.P.S.S.C.E. 200
30. Explain, how a galvanometer can be converted into an a
    meter of a given range.
    (H.S.S.C.E. 2001 ; P.S.S.C.E. 1999 S ; 1998
31. Which one has more resistance : ammeter or galvanomet
    and why ? Also explain, why ammeter is connected
    series in the circuit. *(P.S.S.C.E. 1999*
32. Explain, how you will convert a galvanometer into
    voltmeter of a given range ?
    (P.S.S.C.E. 1999 S ; C.B.S.E. 199

FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. Prove that two parallel conductors of infinite lenghts, carrying currents in the same direction, attract each other. Deduce the expression for the force per unit length exerperienced by each conductor. *(P.S.S.C.E. 2002)*
2. State the principle, construction, theory and limitations
   a cyclotron. *(P.S.S.C.E. 2002 ; C.B.S.E. 200*
3. Discuss the principle, construction, theory and working
   a cyclotron. Why is a cyclotron not suitable for accelerati
   electrons ? *(P.S.S.C.E. 1999 S, 1998 S, 1998, 1997, 1996*

4. Discuss the principle, construction, theory and working of a cyclotron. *(P.S.S.C.E. 2001)*
5. Explain with the help of a labelled diagram, the underlying principle, construction and working of a cyclotron. *(C.B.S.E. 2001, 1997)*
6. Derive an expression for the force acting on a current carrying conductor placed in a uniform magnetic field and using this result derive the expression for torque acting on a current carrying loop suspended in a uniform magnetic field. *(P.S.S.C.E. 2002)*
7. (*a*) Derive an expression for the force experienced by a current carrying straight conductor placed in a magnetic field.
   (*b*) Under what conditions, is this force (*i*) zero and (*ii*) maximum ? State the rule used to determine the direction of this force. *(C.B.S.E. 1998)*
8. Explain with the help of a labelled diagram, the underlying principle, construction and working of a moving coil galvanometer. *(C.B.S.E. 1997)*
9. Describe the principle, construction, theory and two merits of a moving coil galvanometer. *(P.S.S.C.E. 2002)*
10. Discuss the principle, construction and working of a moving coil galvanometer. *(P.S.S.C.E. 2001, 1999, 1998 S ; 1997 S ; Pre-degree Kerela, 1992)*
11. Give the principle, construction and working of a moving coil galvanometer. How can its sensitivity be increased ?
12. Discuss the principle, construction and theory of a dead-beat galvanometer. State its drawback. *(P.S.S.C.E. 2002, 2000)*
13. Explain how a galvanometer can be converted into (*i*) ammeter (*ii*) voltmeter of the required range. *(P.S.S.C.E. 2002)*

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

ype A. On motion of Charged particle inside Electric field

1. An electron beam is deflected by 1·76 mm in travelling a distance of 10 cm through an electric field of 1800 V m^{-1} acting perpendicular to its path. Find the electron charge to mass ratio, if average velocity of the electrons is 3×10^7 m s^{-1}. **[Ans.** $1{\cdot}76 \times 10^{11}$ C kg^{-1}**]**

ype B. On force on a charge moving in magnetic field

2. A proton enters a magnetic field of flux density 2·5 tesla with a velocity of $1{\cdot}5 \times 10^7$ m s^{-1} at an angle of 30° with the field. Find the force on the proton. Charge of the proton = $1{\cdot}602 \times 10^{-19}$ coulomb. *(Pre-degree Kerala, 1994)* **[Ans.** $3{\cdot}0 \times 10^{-12}$ N**]**
3. An electron enters a magnetic field of flux density 3 T with a velocity of 10^6 m s^{-1} at an angle of 30° with the field. Calculate the magnitude of force on the electron. Charge on electron = $1{\cdot}6 \times 10^{-19}$ C. **[Ans.** $2{\cdot}4 \times 10^{-13}$ N**]**
4. A proton of velocity 10^8 cm s^{-1} is moving perpendicular to a uniform magnetic field of 10 kilogauss. What is the sideway force acting on the proton of charge $e = 4{\cdot}8 \times 10^{-10}$ e.s.u. ? **[Ans.** $1{\cdot}6 \times 10^{-13}$ N**]**
5. An electron is moving at 10^6 m s^{-1} in a direction parallel to a current of 5 A, flowing through an infinitely long straight wire, separated by a perpendicular distance of 10 cm in air. Calculate the magnitude of the force experienced by the electron. *(C.B.S.E. 1999)* **[Ans.** $1{\cdot}6 \times 10^{-18}$ N**]**
6. A 5 MeV proton moves vertically downward through a magnetic field of 1·5 weber m^{-2} pointing horizontally from south to north. Calculate the direction of force acting on the proton. Mass of proton = $1{\cdot}7 \times 10^{-27}$ kg and charge = $1{\cdot}6 \times 10^{-19}$ C. **[Ans.** $7{\cdot}37 \times 10^{-12}$ N, from west to east**]**

ype C. On motion of charge inside Magnetic field

7. Electrons move at right angles to a magnetic field of 100 gauss and enter it with a velocity of 2×10^{10} cm s^{-1}. Find the radius of their circular path. Given, $e/m = 1{\cdot}7 \times 10^7$ e.m.u. g^{-1}. **[Ans.** 11·765 cm**]**
8. Find the flux density of the magnetic field to cause 62·5 eV electron to move in a circular path of radius 5 cm. Given, $m = 9{\cdot}1 \times 10^{-31}$ kg , $e = 1 \cdot 6 \times 10^{-19}$ C. **[Ans.** $5{\cdot}335 \times 10^{-4}$ T**]**
9. An electron after being accelerated through a potential difference of 100 V enters a uniform magnetic field of 0·004 T perpendicular to its direction of motion. Calculate the radius of the path described by the electron. Given, $m = 9{\cdot}1 \times 10^{-31}$ kg and $e = 1{\cdot}6 \times 10^{-19}$ C. *(C.B.S.E. 1992)* **[Ans.** 8·42 mm**]**

Type D. On Cyclotron

10. A cyclotron has an oscillator frequency of 12 megahertz and dees of radius 0·5 metre. Calculate the magnetic induction B needed to accelerate deutrons of mass $3{\cdot}34 \times 10^{-27}$ kg and a charge $1{\cdot}6 \times 10^{-19}$ coulomb. Also, calculate the energy acquired by deutrons. **[Ans.** 1·5744 T, 14·843 MeV**]**
11. In a cyclotron, magnetic induction of 1·55 Wb m^{-2} is used. (*i*) What must be the high voltage oscillating frequency of the cyclotron to accelerate deutrons of mass $3{\cdot}34 \times 10^{-27}$ kg and charge numerically equal to that of an electron ? (*ii*) If the radius of the dee is 0·50 m, what is the maximum attainable energy of the deutrons in MeV ? **[Ans.** (*i*) 11·82 MHz ; (*ii*) 14·39 MeV**]**
12. In a cyclotron to accelerate proton, the magnetic field is 15000 gauss and radius of the dees is 15 cm. Calculate the energy of the proton beam and the frequency of the oscillator. Take e/m for proton to be 9580·84 e.m.u. g^{-1} and mass of proton = $1{\cdot}67 \times 10^{-24}$ g. **[Ans.** 2·425 MeV, 22·87 MHz**]**

Type E. On Force on a current carrying conductor

13. A straight conductor carries a current of 1·5 A and is 2 m long. Find the force on it, when it is (*a*) inclined at an angle at 30°, (*b*) perpendicular and (*c*) parallel to a uniform field of 2×10^{-2} T. **[Ans.** (*a*) 0·03 N (*b*) 0·06 N (*c*) zero**]**
14. What is the force on a wire of length 4·0 cm placed inside a solenoid near its centre, making an angle of 60° with its axis ? The wire carries a current of 12 A and the magnetic field due to the solenoid has a magnitude of 0·25 T. **[Ans.** 0·104 N**]**

Type F. On Force between two long straight current carrying conductors

15. A current of 10 A flows through each of two parallel long wires. The wires are 5 cm apart. Calculate the force acting per unit length of each wire. Use the standard value of constant required. *(P.S.S.C.E. 1998)* **[Ans.** 4×10^{-4} N m^{-1}**]**

16. Calculate the force per unit length between two parallel long straight wires 2 cm apart in air, each carrying a current of 4 ampere. (*H.S.S.C.E. 1995*) [**Ans.** $1{\cdot}6 \times 10^{-4}$ N m^{-1}]

17. A current of 5·0 A flows through each of two parallel long wires. The wires are 2·5 cm apart. Calculate the force acting per unit length of each wire. Use standard value of constant required. What will be the direction of force, if both currents flow in the same direction ? (*P.S.S.C.E. 1999*) [**Ans.** 2×10^{-4} N m^{-1}, **repulsive**]

18. Two long straight conductors are placed parallel at a distance of 2 cm from each other. When one of them carries a current of 60 A, the force on 1 m length of the other is 1200 dyne. Calculate current in the other. [**Ans.** 20 A]

19. Two straight wires A and B of lengths 10 m and 12 m carrying currents of 4·0 A and 6·0 A respectively in opposite directions lie parallel to each other at a distance of 4·0 cm. Estimate the force on a 10 cm section of the wire B near its centre. (*H.S.S.C.E. 2001*) [**Ans.** $1{\cdot}2 \times 10^{-5}$ N]

Type G. On Torque on a current loop

20. What torque acts on a 40 turn coil of 100 cm^2 area carrying a current of 10 ampere held with its axis at right angle to magnetic field of flux density 0·2 tesla and plane of the coil parallel to the field ? [**Ans.** 0·8 N m]

21. Calculate the torque on a 50 turn circular coil of radius 10 cm, when placed with its plane at 60° with a magnetic field of $3 \cdot 1 \times 10^{-5}$ T. The current through the coil is 2 A. [**Ans.** $4 \cdot 87 \times 10^{-5}$ N m]

22. A circular coil of 25 turns and radius 6·0 cm, carrying current of 10 A, is suspended vertically in a uniform magnetic field of magnitude 1·2 T. The field lines run horizontally in the plane of the coil. Calculate the force and torque on the coil due to the magnetic field. In which direction, should a balancing torque be applied to prevent the coil from turning ?
[**Ans.** Zero, 3·393 N m (vertically upwards), 3·393 N m (vertically downwards)]

23. A rectangular coil of sides 8 cm and 6 cm having 2000 turns and carrying a current of 200 mA is placed in a uniform magnetic field of 0·2 T directed along positive X-axis. (*a*) What is the maximum torque that the coil can experience ? Also, tell the orientation of the coil (*b*) For which orientation of the coil is the torque zero ?
[**Ans.** (*a*) 0·384 N m (whenever X-axis lies in plane of the coil) ; (*b*) whenever the coil lies in YZ plane]

Type H. On Moving coil galvanometer

24. A moving coil meter has the following particulars. Number of turns, $n = 24$; area of coil ; $A = 2{\cdot}0 \times 10^{-3}$ m^2 ; magnetic field strength, $B = 0{\cdot}20$ T and resistance of the coil, $R = 14\ \Omega$.
(*a*) Indicate a simple way to increase in current sensitivity of the meter by 25%. (It is not easy to change A or B).
(*b*) If in doing so, the resistance of the coil increases to 21 Ω, is the voltage sensitivity of the modified meter greater or less than the original meter ?
[**Ans.** (*a*) increase n from 24 to 30 ; (*b*) lesser]

25. To increase the current sensitivity of a moving coil galvanometer by 50%, its resistance is increased so that its new resistance becomes twice its initial resistance. By what factor does its voltage sensitivity change ? (*C.B.S.E. 2001*) [**Ans.** 25% (decrease)]

26. In an exercise to increase current sensitivity by 25%, its resistance is also increased by 50%. How will the voltage sensitivity of the galvanometer be affected ? (*P.S.S.C.E. 1999 S*) [**Ans.** 16·67% (decreases)]

Type I. On Conversion of galvanometer into ammete and voltmeter

27. A resistance of 900 Ω is connected in series with
galvanometer of resistance 100 Ω. A potential difference
1 V produces a deflection of 100 divisions in th
galvanometer. Find the figure of merit of galvanometer
[**Ans.** 10^{-5} A division

28. How will you convert a 1·0 mA full scale deflection mete
of resistance 100 Ω into an ammeter to read upto 1·0 A
(*P.S.S.C.E. 1997*) [**Ans.** 0·1 Ω in paralle

29. Resistance of a galvanometer is 25 Ω. It can carry a curre
of 0·5 mA. How can it be used to measure a current up
one ampere ? (*Pre-degree Kerala, 199*
[**Ans.** $1{\cdot}25 \times 10^{-2}$ Ω (in parallel

30. It is intended to measure a maximum current of 25 A wi
an ammeter of range 2·5 A and resistance of 0·9 Ω. Ho
can it be done ? [**Ans.** 0·1 Ω (in parallel

31. A galvanometer has a resistance of 10 ohm. It give
maximum deflection for a current of 50 mA. Find the shu
resistance required to convert it into ammeter of rang
2·5 A. What is the resistance of ammeter so constructed
[**Ans.** 0·204 Ω (in parallel), 0·2

32. In a galvanometer, there is a deflection of 10 divisions p
mA. The internal resistance of the galvanometer is 60
If a shunt of 2·5 Ω is connected to the galvanometer an
there are 50 divisions in all on the scale of the galvanomete
calculate the maximum current which the galvanomet
can read. (*C.B.S.E. 2001 S*) [**Ans.** 0·125

33. The coil of a galvanometer has a resistance 100 Ω. It give
full scale deflection for a current of 5×10^{-4} A. How w
you convert it into a voltmeter of 5 V range ?
(*H.S.S.C.E. 1999 S*) [**Ans.** 9900

34. How will you convert a 1 mA full scale deflection met
of resistance 100 Ω into an ammeter to read 1 A (full sca
deflection) and into a voltmeter to read 1 volt (full sca
deflection). (*C.B.S.E. Sample Q. Pape*
[**Ans.** 0·1 Ω (in parallel) ; 900 Ω (in series

35. A galvanometer with a coil of resistance 12·0 Ω shows fu
scale deflection for a current of 2·5 mA. How will yo
convert the meter into (*a*) an ammeter of range 0 to 7·5
and (*b*) a voltmeter of range 0 to 10·0 V ? Determine th
net resistance of the meter in each case. (*Text Proble*
[**Ans.** (*a*) 4×10^{-3} Ω ; 4×10^{-3} Ω, (*b*) 3988 Ω ; 4000

36. A voltmeter reads up to 3 V. Its resistance is 200 oh
It is to be used to measure a potential difference, whic
may be as large as 60 V. What measures you would ta
to protect the voltmeter ?
[**Ans.** connect a series resistance of 3800

Type J. On Ammeter and Voltmeter

37. A battery of e.m.f. 3 volt and internal resistance r
connected in series with a resistor of 55 Ω through a
ammeter of resistance 1 Ω. The ammeter reads 50 mA
Calculate the value of r. (*Pre-degree Kerala, 199*
[**Ans.** 4

38. A cell of e.m.f. 2 volt and internal resistance 0·1 oh
supplies a current through a coil of resistance 11·9 ohn
The current is being measured by an ammeter, whos
resistance is 6 ohm. What reading does it give ? Wh
is the percentage difference from the actual current, whe
the meter is not used ? [**Ans.** 1/9 A, 33·3%

39. Two resistance coils of 100 Ω and 200 Ω respectively a
connected in series across 100 V. A moving coil voltmet
of 200 Ω is connected in turn across each coil. What will
read in each case ? (*Karnataka, 1986*) [**Ans.** 25 V, 50

40. A battery of e.m.f. 12 V supplies a current through a coil of resistance 48 ohm. The internal resistance of the battery is 1·2 ohm. A voltmeter of resistance 72 ohm is used to measure the potential difference across the coil. What value would it show ? [**Ans.** 11·52 V]

41. A current is being measured in a circuit, consisting of a battery of 12 V and a resistor of resistance 22 ohm. The potential difference measured across the resistor by an accurate voltmeter is 11 V. If the current is to be measured with an ammeter with an error not greater than 10%, what is the maximum permissible resistance of the ammeter ? [**Ans.** 2·67 Ω]

MISCELLANEOUS PROBLEMS

42. A uniform magnetic field of 3000 G is established along the positive Z-direction. A rectangular loop of sides 10 cm and 5 cm carries a current of 12 A. What is the torque on the loop in the four cases shown in the Fig. 2.43 ?

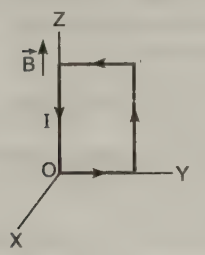

Fig. 2.43 (*a*)

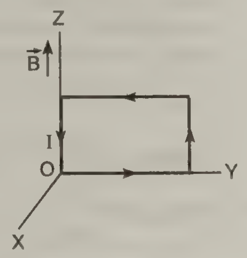

Fig. 2.43 (*b*)

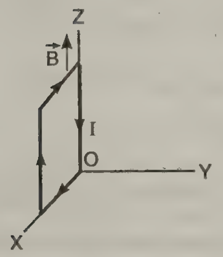

Fig. 2.43 (*c*)

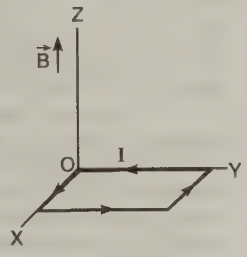

Fig. 2.43 (*d*)

[**Ans.** (*a*) $1\cdot8\times10^{-2}$ N m (along Y′-axis), (*b*) same as in (*a*), (*c*) $1\cdot8\times10^{-2}$ N m (along X′-axis), (*d*) zero]

43. A galvanometer coil is 2 cm square and contains 100 turns. Its period is 20 s and its moment of inertia is 2 g cm^2. The field of the magnet is 0·2 T. Determine the current sensitivity of the galvanometer. [**Ans.** 23·2° μA^{-1}]

44. A galvanometer has a sensitivity of 60 divisions A^{-1}. When a shunt is used, its sensitivity becomes 10 divisions A^{-1}. What is the value of shunt used, if the resistance of galvanometer is 20 Ω. [**Ans.** 4 Ω]

45. A galvanometer has a resistance of 8 Ω and gives full scale deflection, when a current of 10 mA is passed through it. The only shunt resistance available is 0·02 Ω, which is not appropriate to convert the galvanometer into an ammeter of range 5 A. To achieve this, a resistance R is connected in series with the coil of the galvanometer as shown in Fig. 2.44. Find the value of R. [**Ans.** 1·98 Ω]

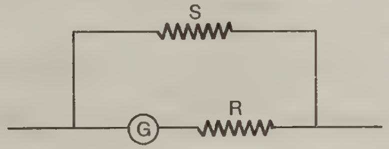

Fig. 2.44.

46. A voltmeter reads 5·0 V at full scale deflection and is graded according to the resistance per volt at full scale deflection as 10,000 Ω V^{-1}. How will you convert it into a voltmeter that reads 25 V at full scale deflection ?

(*C.B.S.E. 2001 S*) [**Ans.** 200 kΩ (in series)]

47. It is required to convert a galvanometer of current range 15 mA and voltage range 750 mV into (*a*) an ammeter of range 25 A and (*b*) a voltmeter of range 150 V. Calculate the value of necessary resistance in each case.

(*Text Problem*) [**Ans.** (*a*) 0·03 Ω, (*b*) 9950 Ω]

48. The scale of a galvanometer is divided into 150 equal divisions. The galvanometer has the current sensitivity of 10 divisions mA^{-1} and the voltage sensitivity of 2 divisions mV^{-1}. How the galvanometer be designed to read (*a*) 6 A division^{-1} and (*b*) 1 V division^{-1}. (*Roorkee 1999*)

[**Ans.** (*a*) $8\cdot33\times10^{-5}$ Ω (in parallel), (*b*) 9995 Ω (in series)]

49. In the circuit shown in Fig. 2.45, the voltmeter reads 117 V and the ammeter reads 0·13 A. The resistance of voltmeter and ammeter are 9000 Ω and 0·015 Ω respectively. Find the value of R. [**Ans.** 1000 Ω]

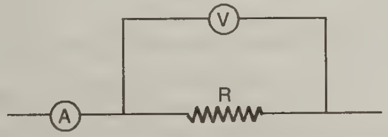

Fig. 2.45

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Time taken by electron to traverse the electric field,

$$t=\frac{10\times10^{-2}}{3\times10^{7}}=3\cdot33\times10^{-9}\text{ s}$$

Acceleration of electron along the electric field,

$$a=\frac{e\text{E}}{m}=\frac{e}{m}\times1800\text{ m s}^{-2}$$

Now, $\text{S}=ut+\frac{1}{2}at^2$

Here, S = 1·76 mm = $1\cdot76\times10^{-3}$ m and $u=0$,

$$\therefore\ 1\cdot76\times10^{-3}=0\times3\cdot33\times10^{-9}+\frac{1}{2}\frac{e}{m}\times1800\times(3\cdot33\times10^{-9})^2$$

or $\frac{e}{m}=\mathbf{1{\cdot}76\times10^{11}\ C\ kg^{-1}}$

2. $\text{F}=qv\text{B}\sin\theta=1\cdot602\times10^{-19}\times1\cdot5\times10^{7}\times2\cdot5\times\sin30°$

$=\mathbf{3{\cdot}0\times10^{-12}\ N}$

3. Proceed as in problem no. 2.

4. $\text{F}=\text{B}qv\sin\theta$

Here, B = 10 kilogauss $=10\times10^{3}\text{ G}=\frac{10\times10^{3}}{10^{4}}=1\text{ T}$,

$v=10^{8}\text{ cm s}^{-1}=10^{6}\text{ m s}^{-1}$,

$q=4\cdot8\times10^{-10}$ e.s.u. of change

$=\frac{4\cdot8\times10^{-10}}{3\times10^{9}}=1\cdot6\times10^{-19}\text{ C}$

$\therefore$ $\text{F}=1\times1\cdot6\times10^{-19}\times10^{6}\sin90°=\mathbf{1{\cdot}6\times10^{-13}\ N}$

Aliter. B = 10 kilograms = 10^4 G,

$q=\frac{4\cdot8\times10^{-10}}{3\times10^{10}}=1\cdot6\times10^{-20}$ e.m.u. of charge

Now, $\text{F}=\text{B}qv\sin\theta=10^{4}\times1\cdot6\times10^{-20}\times10^{8}\times\sin90°$

$=1\cdot6\times10^{-8}\text{ dyne}=\mathbf{1{\cdot}6\times10^{-13}\ N}$

5. Magnetic field produced due to straight conductor,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2I}{a} = \frac{10^{-7} \times 2 \times 5}{10 \times 10^{-2}} = 10^{-5}\ \text{T}$$

Now, $F = B\,q\,v \sin\theta = 10^{-5} \times 1{\cdot}6 \times 10^{-19} \times 10^{6} \sin 90°$

$= \mathbf{1{\cdot}6 \times 10^{-18}\ N}$

6. Here, $\frac{1}{2} m v^2 = 5\ \text{MeV} = 5 \times 1{\cdot}6 \times 10^{-13} = 8 \times 10^{-13}\ \text{J}$

$$\therefore \quad v = \sqrt{\frac{2 \times 8 \times 10^{-13}}{m}} = \sqrt{\frac{2 \times 8 \times 10^{-13}}{1{\cdot}7 \times 10^{-27}}}$$

$= 3{\cdot}07 \times 10^{7}\ \text{m s}^{-1}$

Now, $F = B\,q\,v \sin\theta$

$= 1{\cdot}5 \times 1{\cdot}6 \times 10^{-19} \times 3{\cdot}07 \times 10^{7} \times \sin 90°$

$= \mathbf{7{\cdot}37 \times 10^{-12}\ N}$

To find direction of force : Force on the proton acts in the direction of vector $q(\vec{v} \times \vec{B})$ *i.e.* from **west to east** as depicted in Fig. 2.46

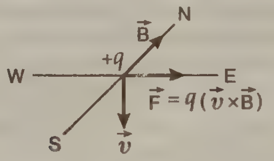

Fig. 2.46

7. Now, $\frac{m v^2}{r} = B\,e\,v$ or $r = \frac{m v}{B e}$

or $r = \frac{v}{B(e/m)} = \frac{2 \times 10^{10}}{100 \times 1{\cdot}7 \times 10^{7}} = \mathbf{11{\cdot}765\ cm}$

8. Here, $\frac{1}{2} m v^2 = 62{\cdot}5\ \text{eV} = 62{\cdot}5 \times 1{\cdot}6 \times 10^{-19} = 10^{-17}\ \text{J}$

or $v = \sqrt{\frac{2 \times 10^{-17}}{m}} = \sqrt{\frac{2 \times 10^{-17}}{9{\cdot}1 \times 10^{-31}}}$

$= 4{\cdot}69 \times 10^{6}\ \text{m s}^{-1}$

Now, $\frac{m v^2}{r} = B\,e\,v$ or $B = \frac{m v}{e r}$

$$\therefore \quad B = \frac{9{\cdot}1 \times 10^{-31} \times 4{\cdot}69 \times 10^{6}}{1{\cdot}6 \times 10^{-19} \times 5 \times 10^{-2}} = \mathbf{5{\cdot}335 \times 10^{-4}\ T}$$

9. Here, energy of electron, $\frac{1}{2} m v^2 = 100\ \text{eV}$

Now, proceed as in problem no. 8.

10. Proceed as in solved problem no. 2.09.

11. *(i)* $\nu = \frac{B e}{2\pi m} = \frac{1{\cdot}55 \times 1{\cdot}6 \times 10^{-19}}{2\pi \times 3{\cdot}34 \times 10^{-27}}$

$= 11{\cdot}82 \times 10^{6}\ \text{Hz} = \mathbf{11{\cdot}82\ MHz}$

(ii) Proceed as in solved problem no. 2.09.

12. $E_{max} = \frac{B^2 e^2 R^2}{2m} = \frac{B^2 (e/m)^2 R^2 m}{2}$

$$= \frac{(15000)^2 \times (9580{\cdot}84)^2 \times (15)^2 \times 1{\cdot}67 \times 10^{-24}}{2}$$

$= 3{\cdot}88 \times 10^{-6}\ \text{erg} = 3{\cdot}88 \times 10^{-13}\ \text{J}$

$= \frac{3{\cdot}88 \times 10^{-13}}{1{\cdot}6 \times 10^{-13}} = \mathbf{2{\cdot}425\ MeV}$

Also, $\nu = \frac{B e}{2\pi m} = \frac{B(e/m)}{2\pi} = \frac{15000 \times 9580{\cdot}84}{2\pi}$

$= 22{\cdot}87 \times 10^{6}\ \text{Hz} = \mathbf{22{\cdot}87\ MHz}$

13. $F = B\,I\,l \sin\theta$

(a) $F = 2 \times 10^{-2} \times 1{\cdot}5 \times 2 \times \sin 30° = \mathbf{0{\cdot}03\ N}$

(b) $F = 2 \times 10^{-2} \times 1{\cdot}5 \times 2 \times \sin 90° = \mathbf{0{\cdot}06\ N}$

(c) $F = 2 \times 10^{-2} \times 1{\cdot}5 \times 2 \times \sin 0° = \mathbf{0}$

14. Proceed as in problem no. 13.

15. Proceed as in solved problem no. 2.11.

16. Proceed as in solved problem no. 2.11.

17. Proceed as in solved problem no. 2.11.

18. Here, $F = 1200$ dyne $= 1200 \times 10^{-5}$ N,

$I_1 = 60$ A, $r = 2$ cm $= 0{\cdot}02$ m

Now, $F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r}$

or $1200 \times 10^{-5} = 10^{-7} \times \frac{2 \times 60 \times I_2}{0{\cdot}02}$

or $\mathbf{I_2 = 20\ A}$

19. The lengths of two conductors is quite large as compared to the separation between them. Therefore, the two conductors may be considered as infinitely long and hence force on unit length of wire B due to A,

$$F = \frac{\mu_0}{4\pi} \cdot \frac{2 I_1 I_2}{r} = \frac{10^{-7} \times 2 \times 4 \times 6}{4{\cdot}0 \times 10^{-2}} = 1{\cdot}2 \times 10^{-4}\ \text{N m}^{-1}$$

Therefore, force on 10 cm (or 0·1 m) section of wire B,

$F' = F \times 0{\cdot}1 = 1{\cdot}2 \times 10^{-4} \times 0{\cdot}1 = \mathbf{1{\cdot}2 \times 10^{-5}\ N}$

20. Here, $\alpha = 0°$

Now, $\tau = n\,B\,I\,A \cos\alpha = 40 \times 0{\cdot}2 \times 10 \times 100 \times 10^{-4} \cos 0°$

$= \mathbf{0{\cdot}8\ N\ m}$

21. Here, $A = \pi r^2 = \pi \times (10)^2\ \text{cm}^2 = \pi \times 10^{-2}\ \text{m}^2$ and $\alpha = 60°$

Now, proceed as in problem no. 20.

22. Proceed as in problem no. 21.

23. Here $A = 8 \times 6 = 48\ \text{cm}^2 = 48 \times 10^{-4}\ \text{m}^2$,

$I = 200\ \text{mA} = 200 \times 10^{-3}\ \text{A}$

(a) Now, $\tau = n\,B\,I\,A \cos\alpha$,

where α is angle between plane of the coil and direction of magnetic field. Therefore, coil will experience maximum torque, when $\alpha = 0°$.

Hence, $\tau_{max} = 2000 \times 0{\cdot}2 \times 200 \times 10^{-3} \times 48 \times 10^{-4} \times \cos 0°$

$= \mathbf{0{\cdot}384\ N\ m}$

The angle α will be zero, whenever magnetic field is parallel to the plane of the coil *i.e.* X-axis is in the plane of coil.

(b) The torque on coil will be zero, when $\alpha = 90°$ *i.e.* magnetic field is perpendicular to the plane of the coil. In other words, when coil lies in YZ-plane, torque on the coil is zero.

24. *(a)* Current sensitivity, $\frac{\alpha}{I} = \frac{n A B}{k}$

Since it is not easy to change A or B, current sensitivity may be increased by changing n (number of turns in the coil). Suppose that number of turns in the coil are changed from n to n' so as to increase current sensitivity by 25%.

Then, modified current sensitivity,

$$\frac{\alpha'}{I} = \frac{n' A B}{k}$$

Now, $\frac{\alpha'}{I} = \frac{125}{100} \times \frac{\alpha}{I}$ or $\frac{n' A B}{k} = \frac{125}{100} \times \frac{n A B}{k}$

or $n' = \frac{125}{100} \times n = \frac{125 \times 24}{100} = \mathbf{30}$

(b) Initial voltage sensitivity, $\frac{\alpha}{I R} = \frac{n A B}{k R}$

$$= \frac{24 \times 2{\cdot}0 \times 10^{-3} \times 0{\cdot}20}{k \times 14} = \frac{6{\cdot}857 \times 10^{-4}}{k}$$

Voltage sensitivity of modified meter, $\frac{\alpha}{IR'} = \frac{n'AB}{kR'}$

$$= \frac{30\times 2\cdot0\times10^{-3}\times0\cdot20}{k\times21} = \frac{5\cdot714\times10^{-4}}{k}$$

i.e. voltage sensitivity becomes **lesser**.

25. Proceed as in solved problem no. 2.20.
26. Proceed as in solved problem no. 2.20.
27. Here, G = 100 Ω, R = 900 Ω, V = 1 V

Therefore, current through the galvanometer,

$$I_g = \frac{V}{R+G} = \frac{1}{900+100} = 10^{-3}\text{ A}$$

Now, figure of merit

= current that produces a deflection of 1 division

$$= \frac{10^{-3}}{100} = \mathbf{10^{-5}\text{ A division}^{-1}}$$

28. Proceed as in solved problem no. 2.21.
29. Proceed as in solved problem no. 2.21.
30. Proceed as in solved problem no. 2.21.
31. Proceeding as in solved problem no. 2.21, it can be obtained that

S = **0·204 Ω (in parallel)**

Therefore, resistance of ammeter so constructed,

$$R_A = \frac{GS}{G+S} = \frac{10\times0\cdot204}{10+0\cdot204} = \mathbf{0\cdot2\ \Omega}$$

32. Here, $I_g = \frac{1}{10}\times50 = 5\text{ mA} = 5\times10^{-3}\text{ A}$

G = 60 Ω and S = 2·5 Ω

Now, $S = \frac{I_g G}{I-I_g}$ or $I = \frac{I_g G}{S}+I_g$

or $I = \frac{5\times10^{-3}\times60}{2\cdot5}+5\times10^{-3} = 125\times10^{-3}\text{ A}$

= **0·125 A**

33. Proceed as in solved problem no. 2.24 (*b*).
34. Proceed in as solved problem no. 2.24.
35. Proceed in as solved problem no. 2.24.
36. Here, $R_V = 200\ \Omega$

Current for full scale deflection, $I_g = \frac{3}{200} = 1\cdot5\times10^{-2}\text{ A}$

To increase the range of voltmeter from 3 V to 30 V, the resistance to be connected in series to the voltmeter is given by

$$R = \frac{V}{I_g} - R_V = \frac{60}{1\cdot5\times10^{-2}} - 200 = \mathbf{3800\ \Omega}$$

37. Here E = 3 V ; R = 55 Ω and $R_A = 1\ \Omega$

Now, $I = \frac{E}{R+r+R_A}$ or $50\times10^{-3} = \frac{3}{55+r+1}$

or $r = \frac{3}{50\times10^{-3}} - 56 = 60-56 = \mathbf{4\ \Omega}$

38. Here, E = 2 V, r = 0·1 Ω, R = 11·9 Ω, $R_A = 6\ \Omega$

Therefore, reading of the ammeter,

$$I = \frac{E}{R+r+R_A} = \frac{2}{11\cdot9+0\cdot1+6} = \mathbf{\frac{1}{9}\text{ A}}$$

Actual current in the circuit (in the absence of ammeter),

$$I' = \frac{E}{R+r} = \frac{2}{11\cdot9+0\cdot1} = \frac{1}{6}\text{ A}$$

$$\%\text{ difference} = \frac{I'-I}{I'}\times100 = \frac{1/6-1/9}{1/6}\times100 = \mathbf{33\cdot3\%}$$

39. Here, $R_1 = 100\ \Omega$; $R_2 = 200\ \Omega$, $R_V = 200\ \Omega$ and E = 100 V

When voltmeter is connected across R_1:

Let R_p be resistance of parallel combination of R_1 and R_v. Then,

$$R_p = \frac{R_1\times R_V}{R_1+R_V} = \frac{100\times200}{100+200} = \frac{200}{3}\ \Omega$$

Therefore, current in circuit,

$$I = \frac{E}{R_2+R_p} = \frac{100}{200+200/3} = \frac{3}{8}\text{ A}$$

Hence, reading of voltmeter

$$= I\times R_p = \frac{3}{8}\times\frac{200}{3} = \mathbf{25\text{ V}}$$

When voltmeter is connected across R_2:

$$R_p' = \frac{R_2\times R_V}{R_2+R_V} = \frac{200\times200}{200+200} = 100\ \Omega$$

$$I' = \frac{E}{R_1+R_p'} = \frac{100}{100+100} = 0\cdot5\text{ A}$$

Hence, reading of voltmeter $= I'\times R_p' = 0{\cdot}5\times200 = \mathbf{50\text{ V}}$

40. Here, E = 12 V ; r = 1·2 Ω ; R = 48 Ω and $R_V = 72\ \Omega$

Let R_p be resistance of series combination of R and R_V. Then,

$$R_p = \frac{R\times R_V}{R+R_V} = \frac{48\times72}{48+72} = 28\cdot8\ \Omega$$

Therefore, current in the circuit,

$$I = \frac{E}{R_p+r} = \frac{12}{28\cdot8+1\cdot2} = 0\cdot4\text{ A}$$

Hence, reading of the voltmeter

$= I\times R_p = 0{\cdot}4\times28{\cdot}8 = \mathbf{11{\cdot}52\text{ V}}$

41. Here E = 12 V ; R = 22 Ω

Let *r* be the internal resistance of the battery. Then,

current in the circuit, $I = \frac{E}{R+r}$

or $$I = \frac{12}{22+r} \qquad \text{...}(i)$$

Since potential difference across R is 11 V,

$$I = \frac{V}{R} = \frac{11}{22} = 0\cdot5\text{ A}$$

Substituting for I in equation (*i*), we have

$$0\cdot5 = \frac{12}{22+r} \quad \text{or} \quad r = 2\ \Omega$$

Let R_A be resistance of the ammeter. When ammeter is connected in circuit, current in the circuit will decrease due to resistance of the ammeter. Let I′ be the current measured by the ammeter. Then,

$$I' = \frac{E}{R+r+R_A} = \frac{12}{22+2+R_A}$$

or $$I' = \frac{12}{24+R_A}$$

Now, $I' = I\times\frac{90}{100}$ or $\frac{12}{24+R_A} = 0\cdot5\times\frac{90}{100} = 0\cdot45$

or $R_A = \frac{12}{0\cdot45} - 24 = 26\cdot67 - 24 = \mathbf{2{\cdot}67\ \Omega}$

42. Here, $B = 3000\text{ G} = 3000\times10^{-4} = 0{\cdot}3\text{ T}$,

$A = 10\times5 = 50\text{ cm}^2 = 50\times10^{-4}\text{ m}^2$, I = 12 A,

$\therefore IA = 50\times10^{-4}\times12 = 0{\cdot}06\text{ A m}^2$

(*a*) Here, $I\vec{A} = 0{\cdot}06\,\hat{i}\ \text{A m}^2$ and $\vec{B} = 0{\cdot}03\,\hat{k}\ \text{T}$

Now, $\vec{\tau} = (I\vec{A}) \times \vec{B} = 0{\cdot}06\,\hat{i} \times 0{\cdot}03\,\hat{k} = -1{\cdot}8 \times 10^{-2}\,\hat{j}\ \text{N m}$
i.e. torque equal to **$1{\cdot}8 \times 10^{-2}$ N m acts along the negative Y-axis.**

(*b*) Here, $I\vec{A} = 0{\cdot}06\,\hat{i}\ \text{A m}^2$ and $I\vec{B} = 0{\cdot}03\,\hat{k}\ \text{T}$

Since $I\vec{A}$ and $\vec{B}$ are same as in case (*a*), torque in this case also is equal to **$1{\cdot}8 \times 10^{-2}$ N m and acts along the negative Y-axis.**

(*c*) Here, $I\vec{A} = -0{\cdot}06\,\hat{j}\ \text{A m}^2$ and $\vec{B} = 0{\cdot}03\,\hat{k}\ \text{T}$

Now, $\vec{\tau} = (I\vec{A}) \times \vec{B} = -0{\cdot}06\,\hat{j} \times 0{\cdot}03\,\hat{k} = -1{\cdot}8 \times 10^{-2}\,\hat{i}\ \text{N m}$
i.e. torque equal to **$1{\cdot}8 \times 10^{-2}$ N m acts along the negative X-axis.**

(*d*) Here, $I\vec{A} = 0{\cdot}06\,\hat{k}\ \text{A m}^2$ and $\vec{B} = 0{\cdot}03\,\hat{k}\ \text{T}$

Now, $\vec{\tau} = (I\vec{A}) \times \vec{B} = 0{\cdot}06\,\hat{k} \times 0{\cdot}03\,\hat{k} = 0$

43. Here, $A = 2 \times 2 = 4\ \text{cm}^2 = 4 \times 10^{-4}\ \text{m}^2$; $n = 100$;
$T = 20$ s, $B = 0{\cdot}2$ T
and moment of inertia of the coil, $I = 2\ \text{g cm}^2$
$= 2 \times (10^{-3}\ \text{kg}) \times (10^{-2}\ \text{m})^2 = 2 \times 10^{-7}\ \text{kg m}^2$
When a coil of moment of inertia I is suspended from a wire having restoring torque per unit twist *k*, its period of oscillation is given by

$$T = 2\pi\sqrt{\frac{I}{k}}$$

$$\text{or}\quad k = \frac{4\pi^2 I}{T^2} = \frac{4\pi^2 \times 2 \times 10^{-7}}{(20)^2} = 1{\cdot}974 \times 10^{-8}\ \text{N m rad}^{-1}$$

$$\text{Now, current sensitivity} = \frac{nAB}{k} = \frac{100 \times 4 \times 10^{-4} \times 0{\cdot}2}{1{\cdot}974 \times 10^{-8}}$$
$$= 4{\cdot}053 \times 10^5\ \text{rad A}^{-1}$$
$$= 4{\cdot}053 \times 10^5 \times \left(\frac{180°}{\pi}\right) \times \left(10^6\ \mu\text{A}\right)^{-1}$$
$$= \mathbf{23{\cdot}2°\ \mu A^{-1}}$$

44. Here, $G = 20\ \Omega$
Let *n* be total number of divisions on the galvanometer scale.

Then, $I_g = \dfrac{n}{60}$ A and $I = \dfrac{n}{10}$ A

$$\text{Now,}\quad S = \frac{I_g G}{I - I_g} = \frac{(n/60) \times 20}{n/10 - n/60} = \frac{20}{6 - 1} = \mathbf{4\ \Omega}$$

45. Here, $G = 8\ \Omega$, $I_g = 10\ \text{mA} = 0{\cdot}01$ A, $I = 5$ A and $S = 0{\cdot}02\ \Omega$
When the resistance R is connected in series to the galvanometer, it behaves as a galvanometer of effective resistance,
$G' = G + R = 8 + R$

$$\text{Now,}\quad S = \frac{I_g G'}{I - I_g} \quad \text{or} \quad 0{\cdot}02 = \frac{0{\cdot}01 \times (8 + R)}{5 - 0{\cdot}01}$$

$$\text{or}\quad R = \frac{0{\cdot}02 \times (5 - 0{\cdot}01)}{0{\cdot}01} - 8 = 9{\cdot}98 - 8 = \mathbf{1{\cdot}98\ \Omega}$$

46. Proceed as solved problem no. 2.39.

47. Current range of galvanometer and voltage range of the galvanometer imply the values of current and voltage, which produce full scale deflection in the galvanometer. Thus,
$I_g = 15\ \text{mA} = 15 \times 10^{-3}$ A and $V_g = 750\ \text{mV} = 750 \times 10^{-3}$ V

$$\therefore\quad G = \frac{V_g}{I_g} = \frac{750 \times 10^{-3}}{15 \times 10^{-3}} = 50\ \Omega$$

(*a*) Here, I = 25 A

$$\therefore\ S = \frac{I_g G}{I - I_g} = \frac{15 \times 10^{-3} \times 50}{25 - 15 \times 10^{-3}} = \mathbf{0{\cdot}03\ \Omega}$$

(*b*) Here, V = 150 V

$$\therefore R = \frac{V}{I_g} - G = \frac{150}{15 \times 10^{-3}} - 50 = \mathbf{9950\ \Omega}$$

48. Total number of divisions on galvanometer scale = 150
Current sensitivity of galvanometer = 10 divisions mA⁻¹
Therefore, current required for full scale deflection,

$$I_g = \frac{150}{10} = 15\ \text{mA} = 15 \times 10^{-3}\ \text{A}$$

Voltage that produces full scale deflection,

$$V_g = \frac{150}{2} = 75\ \text{mV}$$

$$\text{Therefore, resistance of galvanometer, } G = \frac{V_g}{I_g} = \frac{75}{15} = 5\ \Omega$$

(*a*) Range of required ammeter, I = 6 × 150 = 900 A

$$\therefore\ S = \frac{I_g G}{I - I_g} = \frac{15 \times 10^{-3} \times 5}{900 - 15 \times 10^{-3}} = \mathbf{8{\cdot}33 \times 10^{-5}\ \Omega\ (in\ parallel)}$$

(*b*) Range of required voltmeter, V = 1 × 150 = 150 V

$$\therefore\ R = \frac{V}{I_g} - G = \frac{150}{15 \times 10^{-3}} = \mathbf{9995\ \Omega\ (in\ series)}$$

49. Here, $R_V = 9000\ \Omega$, $R_A = 0{\cdot}015\ \Omega$
Reading of voltmeter = 117 V
and reading of ammeter = 0·13 A
Suppose that the e.m.f. of the battery in the circuit is E.
Resistance of parallel combination of R_V and R,

$$R_p = \frac{R_V \times R}{R_V + R} = \frac{9000\,R}{9000 + R} \qquad \text{...(}i\text{)}$$

$$\text{Therefore, reading of ammeter, } \frac{E}{R_p + R_A} = 0{\cdot}13$$

$$\text{Also, reading of voltmeter, } \frac{E}{R_p + R_A} \times R_p = 117$$

or $0{\cdot}13 \times R_p = 117$ or $R_p = 900\ \Omega$
Substituting for R_p in equation (*i*), we have

$$\frac{9000\,R}{9000 + R} = 900$$

or $\mathbf{R = 1000\ \Omega}$

CHAPTER

3

Magnetic dipole

3.01. INTRODUCTION

Historically, Thales of Miletus knew that pieces of lodestone or magnetite (black ron oxide *i.e.* Fe_2O_3 – a naturally occurring iron ore) could attract small pieces of ron. Further, these small pieces of iron could themselves acquire this property, if hey came in contact with this ore (lodestone). Later, it was discovered by the Chinese hat a linear piece of lodestone, when suspended freely would come to rest approximately along geographical N – S line. This directional property forms the basis of the principle of the magnetic compass used as an aid to navigation. The Chinese used it as a primitive compass and because of this use, the iron ore 'magnetite' was given the name *lodestone* or *leading stone*. William Gilbert suggested hat the earth itself was a huge magnet. It is due to the earth's magnetism that a magnetic compass needle aligns itself along N– S direction.

The magnetic force and magnetism are basically the effects produced by electrical charges in motion. Oersted discovered the magnetic effect of electric currents. However, the phenomenon of magnetism and some of the basic properties of magnetism were known long before.

Quotable Quote

"The disgrace of the nineteenth century is its ignorance of the subject of magnetism, will the twentieth bring knowledge ?"

– Hermann Von Helmholtz

3.02. ARTIFICIAL BAR MAGNET AND ITS PROPERTIES

Usually, the natural magnets are not strong enough magnetically. Further, because of their odd shapes, the natural magnets are not very convenient for practical use. However, pieces of iron of suitable shapes can be made magnets by rubbing them with a natural magnet. It is found that a steel rod does not acquire magnetism that easily, with which a soft iron rod acquires. But the steel rod retains the magnetism, it has acquired and does not lose it, unless heated to a very high temperature. On the other hand, the soft iron rod which acquires magnetism, even when merely placed near a permanent magnet, loses this property when removed away from it.

When a bar magnet is brought near a heap of iron filings, they cling most near the two ends of the magnet called the poles of the magnet.

Magnetic pole. *The preferred regions of attraction near the two ends of a magnet, where the magnetic force due to bar magnet is maximum, are called the poles of the magnet.*

A bar magnet has the following properties :

1. ***Attractive property.*** A magnet can attract small pieces of magnetic substances like iron, steel, cobalt, nickel, etc. The attraction is maximum at poles. It may be pointed out that the poles are situated near the ends of the magnet and not exactly at the ends.

2. ***Directive property.*** A magnet, when suspended freely, aligns itself approximately along geographical N–S line, such that north pole of the magnet is towards the north of the earth and the south pole is towards the south of the earth as shown in Fig. 3.01.

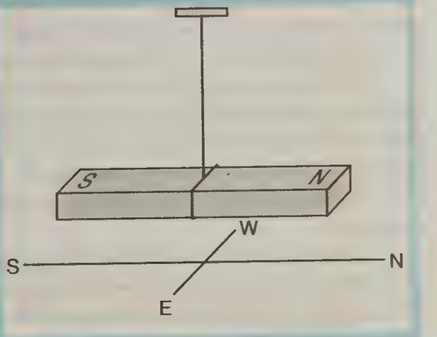

Fig. 3.01

3. ***Unlike poles attract and like poles repel.*** If the S-pole of a magnet is brought near the N-pole of another magnet, they are found to attract each other [Fig. 3.02 (*a*)].

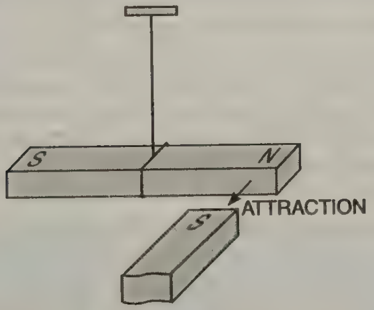

Fig. 3.02 (*a*)

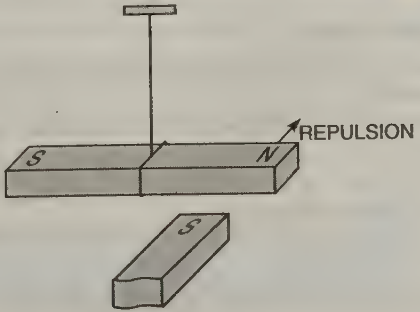

Fig. 3.02 (*b*)

On the other hand, if the N-pole of a magnet is brought near the N-pole of another magnet (or S-pole of a magnet is brought near the S-pole of another magnet), they are found to repel each other [Fig. 3.02 (*b*)]. Therefore, unlike poles attract each other and like poles repel each other.

Key point

An isolated magntic pole does not exist.

4. ***Magnetic poles exist in pairs.*** If a magnet is cut* into two equal parts transverse to its length as shown in Fig. 3.03, N and S-poles of the magnet donot get separated. Each of the two parts is found to be a magnet having north and south poles at the two ends as shown in figure. Further, each part of the magnet possesses the pole strength same as that of the original magnet.

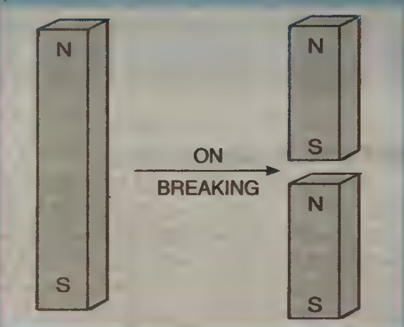

Fig. 3.03

On the other hand, if the magnet is cut into two equal parts along the length of the magnet, each part is found to be a magnet having pole strength exactly half of the pole strength of the original magnet.

Key point

When a magnet having pole strength *m* is cut in two equal parts

(*i*) longitudinally, the pole strength of each new magnet obtained is *m*/2.

(*ii*) transversely, the pole strength of each new magnet still remains *m*.

The important difference in electricity and magnetism is that in electricity, an isolated charge exists, whereas in magnetism, an isolated magnetic pole *i.e.* monopole does not exist.

5. ***Inductive property.*** When a piece of a substance, such as soft iron, steel, cobalt, nickel, etc is placed near a bar magnet, it acquires magnetism. The magnetism so acquired is called *induced magnetism*.

6. ***Repulsion is the surest test for distinguishing between a magnet and a piece of iron.*** The pole of a magnet attracts a piece of iron as well as the unlike pole of an other magnet. Therefore, when the magnet used for distinguishing between a magnet and a piece of iron is brought near the two ends of a specimen, it will show attraction if it is an iron rod ; but will show repulsion at one end, if it is a magnet. Thus, repulsion is the surest test to distinguish between a magnet and a piece of iron.

3.03. ATOMIC VIEW OF MAGNETISM

Ewing modified the molecular theory of magnetism given by Weber. Since a current loop behaves as a magnetic dipole, each atom of a magnetic substance can be considered as a magnetic dipole. It is because, electrons revolving around the nucleus in an atom are equivalent to small current loops. According to Ewing, the molecules of a magnetic substance, whether magnetised or unmagnetised, are all complete magnets. As shown in Fig. 3.04, in an unmagnetised magnetic substance, these molecular magnets (represented by arrows) are randomly oriented and form closed chains. The north pole of one molecular magnet attracts the south pole of its neighbouring molecular magnet, while its own south-pole is attracted by the north pole of another and so on. In this manner, the molecular magnets neutralize the effect of each other and the unmagnetised specimen exhibits no magnetism.

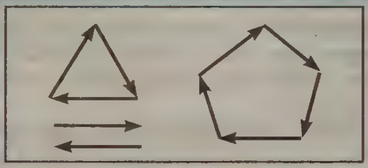

Fig. 3.04

In a bar magnet, the molecular magnets are aligned in the same direction *i.e.* the north-poles of all the molecular magnets point in one direction, while the south-poles in the opposite direction [Fig. 3.05]. Hence, one end behaves as a strong north-pole and other as a strong south-pole. Thus, the difference between a magnetised and unmagnetised substance lies only in the arrangement of these molecular magnets.

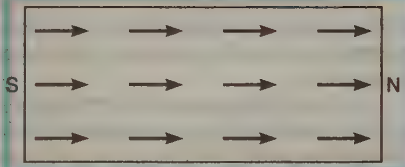

Fig. 3.05

It may be pointed out that Ampere had suggested that the elementary atomic magnets in the magnetic substances were tiny circulating current loops. In principle, this insight of Ampere has turned out to be substantially correct. Now, it is agreed that the atomic magnetism is of electrical origin. However, most part of the atomic magnetism is contributed by the spinning motion of electrons in the atoms, rather than their orbital motion.

3.04. COULOMB'S LAW IN MAGNETISM

In 1785, by making use of his torsion balance, Coulomb discovered the law governing force between two magnetic poles†.

Suppose that two magnetic poles of strengths m_1 and m_2 are placed a distance r apart. Then, force of attraction or repulsion between the two poles is found to be directly proportional to the product of their pole strengths and inversely proportional to the square of the distance between them *i.e.*

$$F \propto \frac{m_1 m_2}{r^2}$$

---

*For details, refer to VSQ 3.03.

†As isolated magnetic poles do not exist, two long magnets were used by Coulomb. It was assumed that the pole of one magnet does not experience any appreciable force due to the distant pole of the other magnet.

or $$F = k\,\frac{m_1\,m_2}{r^2}$$

In SI, the constant of proportionality, $k = \frac{\mu_0}{4\pi} = 10^{-7}$ Wb A^{-1} m^{-1} .

$$\therefore \qquad F = \frac{\mu_0}{4\pi}\cdot\frac{m_1\,m_2}{r^2} = 10^{-7}\times\frac{m_1\,m_2}{r^2} \qquad ...(3.01)$$

Here, μ_0 is called the ***absolute permeability*** of free space.

Unit of magnetic pole strength. Suppose that $m_1 = m_2 = m$ (say)

$r = 1$ m and $F = 10^{-7}$ N

From equation (3.01), we have

$$10^{-7} = 10^{-7}\times\frac{m\times m}{1^2} \qquad \text{or} \qquad m^2 = 1$$

or $m = \pm 1$ ampere metre (A m)

Therefore, *strength of a magnetic pole is said to be one ampere metre, if it repels an qual and similar pole with a force of* 10^{-7} *N, when placed in vacuum* (or air) *at a distance f one metre from it.*

3.05. MAGNETIC DIPOLE AND MAGNETIC DIPOLE MOMENT

A bar magnet has two magnetic poles. It is sometimes also called as magnetic ipole.

Magnetic dipole. *An arrangement of two magnetic poles of equal and opposite trengths separated by a finite distance is called a magnetic dipole.*

The two poles of a magnetic dipole (or a magnet), called north and south poles, re always of equal strength and of opposite nature. Further, such two magnetic oles always exist in pair. In other words, an isolated north or a south pole does ot exist.

Magnetic length. *The distance between the two poles of a bar magnet is called the agnetic length of the magnet.*

Magnetic length is a vector from S-pole of the magnet to its N-pole and is lenoted by $2\vec{l}$ [Fig. 3.06].

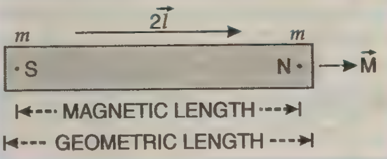

Fig. 3.06

Since the magnetic poles are situated within the magnet, the distance between ts two magnetic poles called its ***magnetic length*** is always less than its ***geometric ength.***

Magnetic dipole moment. *The product of the strength of either pole and the magnetic ength of the magnet is called magnetic dipole moment.*

It is a vector quantity and is represented by $\vec{M}$. Its direction is same as that of $2\vec{l}$ *.e.* from S-pole of the magnet to its N-pole. Thus,

$$\vec{M} = m\,(2\vec{l}) \qquad ...(3.02)$$

In SI, the unit of magnetic dipole moment is **ampere metre^2 (A m^2).**

Note. In place of bar magnet, the term 'magnetic dipole' is also often used for an arrangement of two equal and unlike magnetic poles separated by certain distance.

3.06. MAGNETIC FIELD

The space around a magnet (or a conductor carrying current), *in which its magnetic ffect can be experienced, is called the magnetic field.*

The magnetic field in a region is said to be uniform, if the magnitude of its strength and direction is same at all the points in that region.

A uniform magnetic field is represented by equidistant parallel arrows.

The SI unit of strength of magnetic field (also known as magnetic induction or magnetic induction field or magnetic flux density) is **tesla (T).** It can be measured in terms of force on a charge moving inside the magnetic field or by using the concept of magnetic flux linked with a surface.

1 tesla (T) = 1 newton ampere $^{-1}$ metre^{-1} (N A^{-1} m^{-1})

= 1 weber metre^{-2} (Wb m^{-2})

Note. 1. The strength of magnetic field is also measured in **gauss (G).**

1 gauss (G) = 10^{-4} tesla (T)

2. Usually, the strength of magnetic field B is simply called magnetic field.

3.07. MAGNETIC FIELD LINES

The magnetic field line is the path along which an isolated north pole will tend to move, if it is free to do so.

Since an isolated magnetic pole does not exist, a small magnetic needle is used to plot the field lines of a magnetic field. The magnetic field lines do not exist in reality. The concept of magnetic field lines was developed to visualize the strength of the magnetic field in different regions of the field. The regions, where the magnetic field lines are close enough (crowded), the magnetic field is considered as quite strong there.

Key point

The relative closeness of magnetic field lines in different regions of a magnetic field can be used to adjudge the field strength.

Properties of magnetic field lines. The following are a few important properties of magnetic field lines :

1. The magnetic field lines are closed continuous loops extending through the body of the magnet.
2. Outside the body of the magnet, the magnetic field lines run from north pole to south pole of the magnet.
3. The tangent to the magnetic field line at any point gives the direction of magnetic field at that point.
4. No two magnetic field lines can intersect each other.
5. The magnetic field lines dilate laterally and contract longitudinally.

It may be noted that the electric field of an electric dipole and magnetic field of a bar magnet are also similar. However, there is a fundamental difference between the two fields. In case of the electric field of an electric dipole, the electric lines of force originate from positive charge and end at the negative charge. Since isolated magnetic poles do not exist ; in case of a bar magnet, the magnetic field lines are closed loops. In other words, magnetic field lines do not start or end anywhere. One may imagine them to be extending through the body of the magnet. It is only at far away points that the two fields (electric field of an electric dipole and magnetic field of a bar magnet) look very similar.

Key point

In contrast to electric lines of force, magnetic field lines are always closed loops.

3.08. MAGNETIC FIELD ON AXIAL LINE OF A BAR MAGNET

Consider a bar magnet NS, whose each pole is of strength m. Let $2l$ be magnetic length of the magnet and O be its centre. Let P be a point on the axial line of the magnet at a distance r from the centre of the magnet [Fig. 3.07]

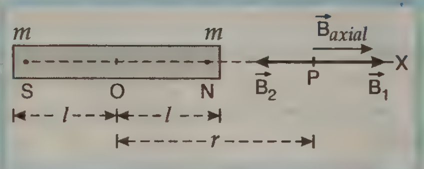

Fig. 3.07

The magnetic field $\vec{B}_{axial}$ at point P due to the bar magnet will be the resultant of the magnetic fields $\vec{B}_1$ (due to N-pole of the magnet) and $\vec{B}_2$ (due to S-pole of the magnet) *i.e.*

$$\vec{B}_{axial} = \vec{B}_1 + \vec{B}_2$$

Now, $$|\vec{B}_1| = \frac{\mu_0}{4\pi} \cdot \frac{m}{NP^2} = \frac{\mu_0}{4\pi} \cdot \frac{m}{(r-l)^2} \quad \text{(along PX)}$$

and $$|\vec{B}_2| = \frac{\mu_0}{4\pi} \cdot \frac{m}{SP^2} = \frac{\mu_0}{4\pi} \cdot \frac{m}{(r+l)^2} \quad \text{(along PS)}$$

It follows that $|\vec{B}_1|$ is greater than $|\vec{B}_2|$.

Since $\vec{B}_1$ and $\vec{B}_2$ act along the same line but in opposite directions,

$$|\vec{B}_{axial}| = |\vec{B}_1| - |\vec{B}_2| \quad \text{(along PX)}$$

or $$B_{axial} = \frac{\mu_0}{4\pi} \cdot \frac{m}{(r-l)^2} - \frac{\mu_0}{4\pi} \cdot \frac{m}{(r+l)^2}$$

$$= \frac{\mu_0}{4\pi} \cdot m \left[\frac{(r+l)^2 - (r-l)^2}{(r^2 - l^2)^2}\right] = \frac{\mu_0}{4\pi} \cdot \frac{m(4rl)}{(r^2 - l^2)^2}$$

Now, $m(2l) = M$, magnitude of the magnetic dipole moment of the magnet.

$$\therefore \quad B_{axial} = \frac{\mu_0}{4\pi} \cdot \frac{2Mr}{(r^2 - l^2)^2} \quad \text{(along PX)} \qquad \text{...(3.03)}$$

It may be noted that the direction of magnetic field due to a bar magnet at a point on its axial line is from S-pole to N-pole *i.e.* same as that of magnetic dipole moment of the bar magnet. Therefore, equation (3.03) may be expressed as

$$\vec{B}_{axial} = \frac{\mu_0}{4\pi} \cdot \frac{2\vec{M}r}{(r^2 - l^2)^2} \qquad \text{...(3.04)}$$

Key point

Magnetic field due to a bar magnet at a point on its axial line has the same direction as that of its magnetic dipole moment vector.

When bar magnet is of very small length. For a bar magnet of very small ngth,

$$l << r$$

d hence in equation (3.03), l^2 can be neglected in comparison to r^2. Therefore, for very short bar magnet,

$$B_{axial} = \frac{\mu_0}{4\pi} \cdot \frac{2M}{r^3} \qquad \text{(along PX)} \qquad ...(3.05)$$

3.09. MAGNETIC FIELD ON EQUITORIAL LINE OF A BAR MAGNET

Consider a bar magnet NS, whose each pole is of strength m. Let $2\,l$ be the agnetic length of the bar magnet and O be its centre. Let P be a point on the quitorial line of the magnet at a distance r from the centre of the magnet [Fig. 3.08].

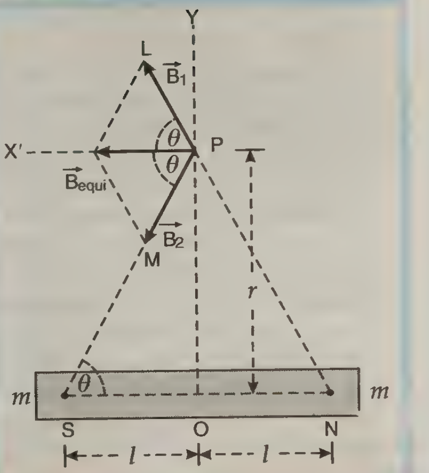

Fig. 3.08

Let $\vec{B}_1$ and $\vec{B}_2$ be the magnetic fields at point P due to N-pole and S-pole of the r magnet. Then, resultant magnetic field at point P due to the bar magnet is given

$$\vec{B}_{equi} = \vec{B}_1 + \vec{B}_2$$

Now, $$|\vec{B}_1| = \frac{\mu_0}{4\pi} \cdot \frac{m}{NP^2} = \frac{\mu_0}{4\pi} \cdot \frac{m}{(r^2+l^2)^2} \qquad \text{(along NP)}$$

and $$|\vec{B}_2| = \frac{\mu_0}{4\pi} \cdot \frac{m}{SP^2} = \frac{\mu_0}{4\pi} \cdot \frac{m}{(r^2+l^2)^2} \qquad \text{(along PS)}$$

It follows that $|\vec{B}_1|$ is equal to $|\vec{B}_2|$. To find the resultant magnetic field at point due to the bar magnet, resolve $\vec{B}_1$ and $\vec{B}_2$ into rectangular components along PX' nd OY. If $\angle PSO = \theta$, then $\angle LPX' = \angle MPX' = \theta$. The components of $\vec{B}_1$ and $\vec{B}_2$ along Y are $|\vec{B}_1| \sin\theta$ and $|\vec{B}_2| \sin\theta$ respectively. As the two components are equal and pposite, they cancel each other. Therefore, resultant magnetic field at point P due the bar magnet,

$$|\vec{B}_{equi}| = |\vec{B}_1| \cos\theta + |\vec{B}_2| \cos\theta \qquad \text{(along PX')}$$

or $$B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{m}{(r^2+l^2)^2} \cos\theta + \frac{\mu_0}{4\pi} \cdot \frac{m}{(r^2+l^2)^2} \cos\theta$$

or $$B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{2m}{(r^2+l^2)^2} \cos\theta$$

From right angled Δ SOP,

$$\cos\theta = \frac{SO}{SP} = \frac{l}{(r^2+l^2)^{1/2}}$$

Hence, $$B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{2m}{(r^2+l^2)} \cdot \frac{l}{(r^2+l^2)^{1/2}}$$

or $$B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{M}{(r^2+l^2)^{3/2}} \qquad \text{(along PX')} \qquad ...(3.06)$$

Here, $M = 2\,m\,l$ is magnetic dipole moment of the bar magnet.

It may be noted that direction of magnetic field due to a bar magnet on its equitorial line is from N-pole to S-pole of the magnet *i.e.* in a direction opposite to hat of the magnetic dipole moment of the magnet. Therefore, equation (3.06) may e expressed as

$$\vec{B}_{equi} = -\frac{\mu_0}{4\pi} \cdot \frac{\vec{M}}{(r^2+l^2)^{3/2}} \qquad ...(3.07)$$

Key point

The direction of magnetic field at a point on its equitorial line is opposite to that of its magnetic dipole moment vector.

When bar magnet is of very small length. For a bar magnet of very small length,

$$l << r$$

and hence in equation (3.06), l^2 can be neglected in comparison to r^2. Therefore, for a very short bar magnet,

$$B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{M}{r^3} \qquad \text{(along PX')} \qquad ...(3.08)$$

Note. From equations (3.05) and (3.08), it follows that magnetic field at a point at a certain distance on the equitorial line of a short bar magnet is just one half of that at the same distance on its axial line.

3.10. TORQUE ON A BAR MAGNET IN A MAGNETIC FIELD

Let a bar magnet N S having pole strength m and of length $2\vec{l}$ be placed in a uniform magnetic field of strength B making an angle θ with the direction of the magnetic field [Fig. 3.09].

Force on N-pole of the magnet = m B (along the direction of magnetic field B)

Force on S-pole of the magnet = m B (opposite to the direction of magnetic field B)

Thus, the bar magnet is acted upon by two equal, parallel and opposite forces. The two forces constitute a torque and it tends to rotate the magnet in the clockwise direction. The magnitude of the torque is given by

$$\tau = \text{either force} \times \text{perpendicular distance between the two forces}$$
$$= mB \times KN$$

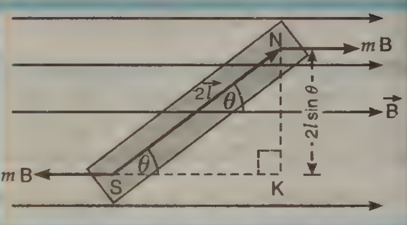

Fig. 3.09

From the right angled triangle N K S, we have

$$KN = NS\sin\theta = 2l\sin\theta$$

$$\therefore \quad \tau = mB \times 2l\sin\theta = m(2l)B\sin\theta$$

Since $m(2l) = M$, the magnetic dipole moment of the bar magnet, we have

$$\tau = MB\sin\theta \qquad ...(3.09)$$

If B = 1 and $\theta = 90°$ *i.e.* $\sin\theta = 1$, then

$$\tau = M \times 1 \times 1 \text{ or } M = \tau$$

Hence, *the magnetic dipole moment of a magnetic dipole is numerically equal to the torque acting on the dipole, when placed perpendicular to the direction of a uniform magnetic field of unit strength.*

In vector notation,

$$\vec{\tau} = \vec{M} \times \vec{B} \qquad ...(3.10)$$

If the vectors $\vec{M}$ and $\vec{B}$ are in the plane of paper [Fig. 3.10], then torque vector $\vec{\tau}$, which acts in the direction of $\vec{M} \times \vec{B}$ will be perpendicular to the plane of the paper and in inward direction.

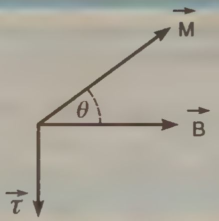

Fig. 3.10

Unit of magnetic dipole moment. From equation (3.09), we have

$$M = \frac{\tau}{B\sin\theta}$$

Therefore, unit of $M = \dfrac{\text{newton metre}}{\text{tesla}} = \text{N m T}^{-1} = \text{J T}^{-1}$

Therefore, magnetic dipole moment may be measured as **newton metre tesla^{-1} (N m T^{-1})** or as **joule tesla^{-1}** (J T^{-1})or as explained in section 1.05, it may be measured as **ampere meter^2** (Am^2). Since tesla is weber metre^{-2}, the magnetic dipole moment is dimensionally equivalent to **joule metre^2 weber^{-1} (J m^2 Wb^{-1}).**

3.11. POTENTIAL ENERGY OF A BAR MAGNET PLACED IN A MAGNETIC FIELD

Let a bar magnet of dipole moment M be placed in a uniform magnetic field of strength B, such that the magnet makes an angle θ with the direction of the field. Then, magnitude of the torque acting on the dipole is given by

$$\tau = MB\sin\theta$$

This torque tends to align the magnet along the direction of the field. If the magnet is rotated against the action of this torque, work has to be done. Suppose that the magnet is rotated through an infinitesimally small angle $d\theta$ under the action of the constant torque τ.

Then, small amount of work done in rotating the magnet through an infinitesimally small angle $d\theta$,

$$dW = \tau\, d\theta = MB\sin\theta\, d\theta$$

If the magnet is rotated from initial position $\theta = \theta_1$ to the final position $\theta = \theta_2$, then the total work done is given by

$$W = \int_{\theta_1}^{\theta_2} MB\sin\theta\, d\theta = MB\int_{\theta_1}^{\theta_2}\sin\theta\, d\theta = MB\left|-\cos\theta\right|_{\theta_1}^{\theta_2}$$
$$= -MB(\cos\theta_2 - \cos\theta_1) = MB(\cos\theta_1 - \cos\theta_2)$$

The work done in rotating the magnet is stored inside the magnet as its potential rgy (U). Thus, potential energy of the magnet inside the magnetic field,

$$U = M B (\cos \theta_1 - \cos \theta_2) \qquad ...(3.11)$$

Suppose that the magnet is initially perpendicular to the direction of the gnetic field *i.e.* $\theta_1 = 90°$. Then, potential energy of the magnet in any position king angle θ with the direction of the field can be obtained by setting $\theta_1 = 90°$ $\theta_2 = \theta$ in equation (3.11) *i.e.*

$$U = M B (\cos 90° - \cos \theta)$$

or

$$U = -M B \cos \theta \qquad ...(3.12)$$

In vector notation, $U = -\vec{M} \cdot \vec{B}$ ...(3.13)

Special cases : Let us find the potential energy of the dipole in following cases :

(i) When $\theta = 0°$, $U = -M B \cos 0° = -M B$ (minimum)

(ii) When $\theta = 90°$, $U = -M B \cos 90° = 0$

iii) When $\theta = 180°$, $U = -M B \cos 180° = M B$ (maximum)

Thus, a magnetic dipole possesses minimum potential energy, when $\vec{M}$ and $\vec{B}$ like parallel and maximum potential energy, when $\vec{M}$ and $\vec{B}$ are antiparallel.

Key point

The energy possessed by a magnetic dipole placed in a magnetic field is minimum, when it is placed along the direction of the field and maximum, when placed anti-parallel to the field.

3.12. CURRENT LOOP AS A MAGNETIC DIPOLE

Consider a circular coil carrying current I. Suppose that the current flows in i-clockwise direction, when seen from above [Fig. 3.11]. The magnetic field lines e to each elementary portion of the circular coil will be of the shape of circular ps near that portion and almost straight near the centre of the circular coil. From t-Savart's law (or right hand thumb rule), it follows that the magnetic field lines m to enter at the lower face of the coil and leave at its upper face. Thus, the lower e of the coil, through which magnetic field lines enter, behaves as the south pole ; ile the upper face, through which the field lines leave, behaves as the north pole. nce, the current carrying circular coil behaves as a magnetic dipole.

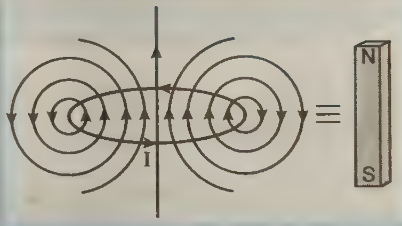

Fig. 3.11

It is found that magnetic dipole moment of the current loop

(i) *is directly proportional to strength of current through the loop i.e.*

$$M \propto I \qquad ...(3.14)$$

(ii) *is directly proportional to area of the current loop i.e.*

$$M \propto A \qquad ...(3.15)$$

Combining equations (3.14) and (3.15), we have

$$M \propto I A$$

or

$$M = k I A,$$

ere k is the constant of proportionality. The constant of proportionality k is found e equal to 1, when current is measured in ampere, area in metre^2 and magnetic ole moment in ampere metre^2. Thus,

$$M = I A \qquad ...(3.16)$$

Since the upper face of the current loop behaves as north pole and the lower e as south pole, the magnetic dipole moment vector $\vec{M}$ acts perpendicular to the ne of the current loop and in upward direction as shown in Fig. 3.12. If $\vec{A}$ is area ctor representing the area of the current loop, then equation (3.16) may be pressed as

$$\vec{M} = I \vec{A} \qquad ...(3.17)$$

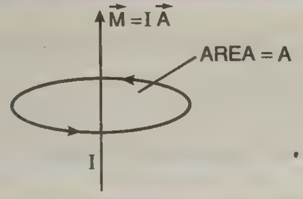

Fig. 3.12

Key point

A planar current loop (of any shape) behaves as a magnetic dipole.

In case the current carrying circular coil has n turns, then

$$M = n I A \qquad ...(3.18)$$

The factor n I is called ***ampere turns*** of the circular current loop. Thus, *magnetic dipole moment of current loop = ampere turns × area of the coil*

The equation (3.18) has been obtained for a circular current loop. In fact, it is e for planar current loop of any shape.

3.13. ATOM AS A MAGNETIC DIPOLE (Magnetic dipole moment of a revolving electron)

In an atom, electrons revolve around the nucleus and as such the circular orbits electrons may be considered as the small current loops. Due to this, an atom ssesses magnetic dipole moment and hence behaves as a magnetic dipole.

Expression for magnetic moment. Let us calculate the magnetic dipole moment an atom due to orbital motion of the electron. Suppose that an electron of mass

m_e and charge e revolves in a circular orbit of radius r around the positive nucleus in anticlockwise direction, as seen from above [Fig. 3.13]. The angular momentum of the electron due to its orbital motion is given by

$$L = m_e\, v\, r \qquad \text{...(3.19)}$$

For the sense of orbital motion of electron shown in the figure, the angular momentum vector $\vec{L}$ acts along normal to the plane of the electron orbit and in upward direction.

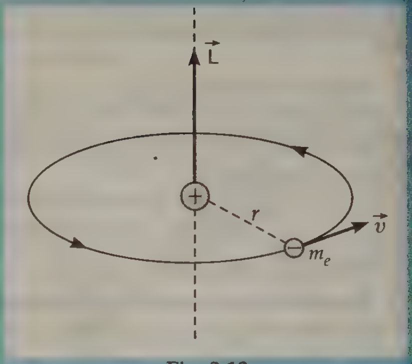

Fig. 3.13

Suppose that the period of orbital motion of the electron is T. Then, the electron crosses any point on its orbit after every T seconds or $\frac{1}{T}$ times in one second. Therefore, orbital motion of electron is equivalent to a current,

$$I = e\left(\frac{1}{T}\right)$$

Now, the period of revolution of the electron is given by

$$T = \frac{2\pi r}{v}$$

Therefore, $$I = e\left(\frac{1}{2\pi r/v}\right) = \frac{e\,v}{2\pi r}$$

The area of the electron orbit (area of current loop), $A = \pi r^2$

Therefore, the magnetic dipole moment of the atom,

$$M = \frac{e\,v}{2\pi r} \times \pi r^2 = \frac{e\,v\,r}{2}$$

Using equation (3.19), we have

$$M = \left(\frac{e}{2\,m_e}\right) L \qquad \text{...(3.20)}$$

In vector notation,

$$\vec{M} = -\left(\frac{e}{2\,m_e}\right)\vec{L} \qquad \text{...(3.21)}$$

The negative sign has been included for the reason that electron has negative charge. The equation (3.21) tells that the magnetic dipole moment vector is directed in a direction opposite to that of angular momentum vector.

According to Bohr's theory, angular momentum of electron in a stationary orbit can have only those values, which are integral multiples of $\frac{h}{2\pi}$ *i.e.*

$$L = n\frac{h}{2\pi},\ \text{where } n = 1, 2, 3... \qquad \text{...(3.22)}$$

From equations (3.20) and (3.22), we have

$$M = \left(\frac{e}{2\,m_e}\right)\frac{n\,h}{2\pi}$$

or $$M = n\left(\frac{e\,h}{4\pi\,m_e}\right) \qquad \text{...(3.23)}$$

The equation (3.23) gives the magnetic moment of an electron due to its orbital motion.

Bohr magneton. *It is defined as the magnetic dipole moment associated with an atom due to orbital motion of an electron in the first orbit of hydrogen atom.*

From equation (3.23), it follows that $\frac{e\,h}{4\pi\,m_e}$ is the least value of the magnetic moment. This natural unit of magnetic moment is called ***Bohr magneton***. It is denoted by μ_B. Its value is

$$\mu_B = \frac{(1{\cdot}6\times10^{-19}\ \text{C})\times(6{\cdot}62\times10^{-34}\ \text{J s})}{4\pi\times(9{\cdot}1\times10^{-31}\ \text{kg})} = 9{\cdot}27\times10^{-24}\ \text{A m}^2$$

We know that in an atom, in addition to orbital motion, an electron has got spin motion also. The electron possesses magnetic moment due to its spin motion also.

e total magnetic moment of the electron is the vector sum of its magnetic moments e to orbital and spin motion.

3.14. BAR MAGNET AS AN EQUIVALENT SOLENOID

Consider a straight solenoid of length L, area of cross-section A and carrying rrent I as shown in Fig. 3.14 (*a*). Each turn of the solenoid behaves as a small agnetic dipole having magnetic dipole moment I A. Therefore, a solenoid can be eated as the arrangement of small magnetic dipoles placed in line with each other shown in Fig. 3.14 (*b*). The number of such small magnetic dipoles is equal to the umber of turns in the solenoid. The south and north poles of these small magnetic poles neutralise each other except at the ends. Thus, a current carrying solenoid n be replaced by just a single south pole and a single north pole separated by a stance equal to the length of the solenoid [Fig. 3.14 (*c*)]. Since each turn of the lenoid behaves a s a small magnetic dipole having dipole moment I A, the uivalent magnetic dipole moment of the solenoid having n turns is n I A.

The magnetic field of a bar magnet or a current carrying solenoid can be plotted using a compass needle. Fig. 3.15 shows the magnetic field produced by a bar agnet, while Fig. 3.16 shows the magnetic field produced by a current carrying lenoid. It follows that the magnetic field produced by a bar magnet is identical that produced by a current carrying solenoid.

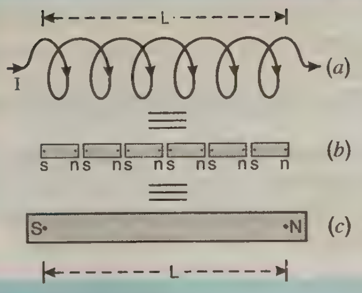

Fig. 3.14

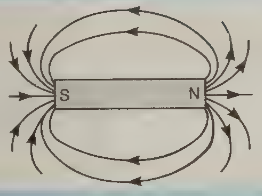

Fig. 3.15

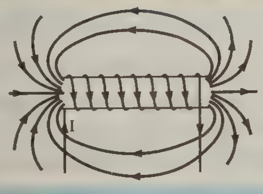

Fig. 3.16

3.15. GAUSS'S LAW IN MAGNETISM*

According to Gauss's law in electrostatic, the surface integral of electric eld $\vec{E}$ over a closed surface S is equal to $\frac{1}{\varepsilon_0}$ times the total charge q enclosed by the rface *i.e.*

$$\oint_S \vec{E}\,.\,d\vec{S} = \frac{q}{\varepsilon_0}$$

An isolated magnetic pole does not exist. In other words, a surface may enclose magnetic dipole *i.e.* a pair of equal and opposite magnetic poles so that net pole rength enclosed by the surface is zero. Therefore, the magnetic analogue of Gauss's w in electrostatic may be stated as

$$\oint_S \vec{B}\,.\,d\vec{S} = 0$$

. surface integral of magnetic field $\vec{B}$ over a closed surface S is always zero. It is called ***auss's law in magnetism.***

Following are a few direct consequences of Gauss's law in magnetism :

1. If a number of magnetic field lines are leaving a closed surface, an equal umber of field lines must also be entering the surface.

2. Isolated magnetic poles do not exist *i.e.* magnetic poles exist in unlike pairs f equal strengths.

Key point

The fact that a magnetic monopole does not exist is a direct consequence of Gauss's law in magnetism.

Key point

Due to the fact that magnetic poles exist in pairs of equal and opposite strengths or that a magnetic monopole does not exist, magnetic flux through a closed surface must always be zero.

SOLVED NUMERICAL PROBLEMS

ype A. On Force between Magnetic poles

Problem 3.01. Two equal magnetic poles placed 5 cm air attract each other with a force of 14·4 × 10^{-4} N. How r from each other should they be placed so that the force f attraction will be 1·6 × 10^{-4} N ?

Sol. Let m be the pole strength of each pole.

In first case : F = 14·4 × 10^{-4} N ; r = 5 cm = 0·05 m

Now, $F = \frac{\mu_0}{4\pi}\cdot\frac{m \times m}{r^2}$ or $14 \cdot 4 \times 10^{-4} = 10^{-7} \times \frac{m^2}{(0 \cdot 05)^2}$

or $m = \pm 6$ A m

In second case : Let r' be the distance between the poles, hen force of attraction becomes F′ = 1·6 × 10^{-4} N.

Now, $F' = \frac{\mu_0}{4\pi}\cdot\frac{m \times m}{r'^2}$ or $1 \cdot 6 \times 10^{-4} = 10^{-7} \times \frac{6 \times 6}{r'^2}$

or r' = **0·15 m**

Problem. 3.02. Two poles, one of which is 5 times as strong as the other, exert on each other a force equal to 0·8 × 10^{-3} kgf, when placed 10 cm apart in air. Find the strength of each pole.

Sol. Let m and 5 m be pole-strengths of the two poles.

Here, F = 0·8 × 10^{-3} kgf = 0·8 × 10^{-3} × 9·8 N,

r = 10 cm = 0·1 m

Now, $F = \frac{\mu_0}{4\pi}\cdot\frac{m_1\, m_2}{r^2}$

or $0 \cdot 8 \times 10^{-3} \times 9 \cdot 8 = \frac{10^{-7} \times m \times 5\,m}{(0 \cdot 1)^2}$

or m = **12·52 A m**

and 5 m = 5 × 12·52 = **62·6 A m**

---

*For additional knowledge only.

Type B. On Magnetic moment

Problem 3.03. Two identical thin bar magnets, each of length L and pole-strength *m* are placed at right angles to each other, with the N-pole of one touching the south pole of the other. Find the magnetic moment of the system.

(I.I.T. 1967)

Sol. When the magnets $N_1 S_1$ and $N_2 S_2$, each of pole strength *m* and length L, are placed at right angles to each other [Fig. 3.17], the system behaves as a magnet, whose pole strength is *m* and length is $N_1 S_2$.

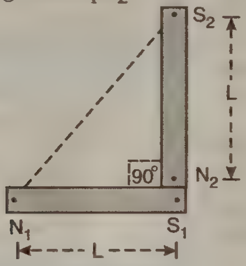

Fig. 3.17

Now, $N_1 S_2 = \sqrt{N_1 S_1^2 + N_2 S_2^2} = \sqrt{L^2 + L^2} = \sqrt{2}\,L$

Therefore, magnetic moment of the system,

$$M = \text{pole strength} \times N_1 S_2 = m \times \sqrt{2}\,L = \sqrt{2}\,m\,L$$

Type C. On Magnetic field due to a bar magnet

Problem 3.04. A bar magnet of length 0 · 1 m has a pole strength of 50 A m. Calculate the magnetic field at distance of 0 · 2 m from its centre on (*i*) its axial line and (*ii*) its equitorial line.

Sol. Here, $m = 50$ A m ; $r = 0{\cdot}2$ m ; $2l = 0{\cdot}1$ m or $l = 0{\cdot}05$ m

Therefore, $M = m\,(2\,l) = 50 \times 0{\cdot}1 = 5$ A m^2

$$(i)\ B_{axial} = \frac{\mu_0}{4\pi} \cdot \frac{2\,M\,r}{(r^2 - l^2)^2}$$

$$= \frac{10^{-7} \times 2 \times 5 \times 0{\cdot}2}{(0{\cdot}2^2 - 0{\cdot}05^2)^2} = \frac{10^{-7} \times 2 \times 5 \times 0{\cdot}2}{(0{\cdot}0375)^2}$$

$$= 1 \cdot 42 \times 10^{-4}\ T$$

$$(ii)\ B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{M}{(r^2 + l^2)^{3/2}}$$

$$= \frac{10^{-7} \times 5}{(0{\cdot}2^2 + 0{\cdot}05^2)^{3/2}} = \frac{10^{-7} \times 5}{(0{\cdot}0425)^{3/2}} = \frac{5 \times 10^{-7}}{0{\cdot}00876}$$

$$= 5 \cdot 708 \times 10^{-5}\ T$$

Problem 3.05. Two identical short bar magnets each of magnetic moment 12·5 A m^2 are placed at a separation of 10 cm between their centres, such that their axes are perpendicular to each other. Find the magnetic field at a point midway between the two magnets.

Sol. Suppose that the two identical magnets $N_1 S_1$ and $N_2 S_2$ are placed as shown in Fig. 3.18. Let P be the point midway between the two magnets.

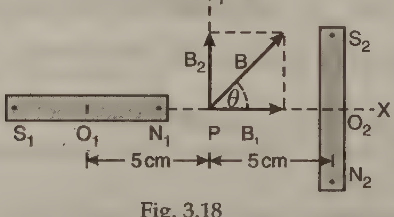

Fig. 3.18

Here, $M_1 = M_2 = 12{\cdot}5$ A m^2

and $O_1P = O_2P = 5$ cm $= 0{\cdot}05$ m

The point P lies on axial line of magnet $N_1 S_1$. If B_1 magnetic field due to magnet $N_1 S_1$ at point P, then

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2\,M_1}{(O_1\,P)^3} = \frac{10^{-7} \times 2 \times 12{\cdot}5}{(0{\cdot}05)^3}$$

$= 0{\cdot}02$ T (along P

The point P lies on equitorial line of magnet $N_2 S_2$. If is magnetic field due to magnet $N_2 S_2$ at point P, then

$$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{M_2}{(O_2\,P)^3} = \frac{10^{-7} \times 12{\cdot}5}{(0{\cdot}05)^3}$$

$= 0{\cdot}01$ T (along P

The resultant magnetic field at point P,

$$B = \sqrt{B_1^2 + B_2^2} = \sqrt{(0{\cdot}02)^2 + (0{\cdot}01)^2}$$

$$= \mathbf{2{\cdot}237 \times 10^{-2}\ T}$$

If θ is the angle which the resultant field makes wi X-axis, then

$$\tan\theta = \frac{B_2}{B_1} = \frac{0{\cdot}01}{0{\cdot}02} = 0{\cdot}5 \text{ or } \theta = \mathbf{26{\cdot}57°}$$

Type D. On Torque on a Bar magnet

Problem 3.06. A bar magnet placed in a unifor magnetic field of strength 0·3 T, with its axis at 30° to th field, experiences a torque of 0·06 N m. What is the magnet mo-ment of the bar magnet ? *(I.S.C.E. 199*

Sol. Here, $B = 0{\cdot}3$ T; $\theta = 30°$; $\tau = 0{\cdot}06$ N m

Now, $\tau = M\,B\sin\theta$

$$\therefore \quad M = \frac{\tau}{B\sin\theta} = \frac{0{\cdot}06}{0{\cdot}3 \times \sin 30°} = \mathbf{0{\cdot}4\ A\ m^2}$$

Problem 3.07. A bar magnet has poles of strength 48 A which are 25 cm apart. (*i*) What is the magnetic moment the magnet ? (*ii*) What torque is required to hold th magnet at an angle 30° with a uniform field of flux densi 0·15 T ?

Sol. Here, $m = 48$ A m ; $2\,l = 25$ cm $= 0{\cdot}25$ m

(*i*) Magnetic moment, $M = m \times 2\,l = 48 \times 0{\cdot}25 =$ **12 A n**

(*ii*) Here, $\theta = 30°$; $B = 0{\cdot}15$ T

Now, $\tau = M\,B\sin\theta = 12 \times 0{\cdot}15 \sin 30° =$ **0·9 N m**

Problem 3.08. A short bar magnet placed with its ax at 30° to a uniform magnetic field of 0·2 T experiences torque of 0·06 N m. (*a*) Calculate the magnetic moment the magnet and (*b*) find out what orientation of the magn corresponds to the stable equilibrium in the magnetic fiel

(C.B.S.E. 200

Sol. Here, $B = 0{\cdot}2$ T ; $\theta = 30°$ and $\tau = 0{\cdot}06$ N m

(*a*) Now, $\tau = M\,B\sin\theta$

$$\therefore \quad M = \frac{\tau}{B\sin\theta} = \frac{0{\cdot}06}{0{\cdot}2 \times \sin 30°} = \mathbf{0{\cdot}6\ A\ m^2}$$

(*b*) The magnet will be in stable equilibrium in th magnetic field, if it experiences no torque due to magnet field *i.e.*

$M\,B\sin\theta = 0$ or $\sin\theta = 0$

or $\theta = 0°$

i.e. when the magnet aligns itself parallel to the magnet field.

Type E. On Potential energy of a Bar magnet

Problem 3.09. A bar magnet of moment 1·5 J T^{-1} li aligned with the direction of a uniform magnetic field

22 T. What is the amount of work required to turn the agnet, so as to align its magnetic moment normal to the eld direction ? What is the torque on the magnet now ? *(Pre-degree Kerala, 1991 ; Text Problem)*

Sol. Here, $M = 1{\cdot}5\ J\ T^{-1}$; $B = 0{\cdot}22\ T$; $\theta_1 = 0°$; $\theta_2 = 90°$

Now, work done to rotate magnet from position θ_1 to , is given by

$$W = M\,B\,(\cos\theta_1 - \cos\theta_2)$$

$$\therefore \quad W = 1{\cdot}5 \times 0{\cdot}22\,(\cos 0° - \cos 90°)$$

$$= 1{\cdot}5 \times 0{\cdot}22\,(1 - 0) = 1{\cdot}5 \times 0{\cdot}22 = \mathbf{0{\cdot}33\ J}$$

Now, $\tau = M\,B \sin\theta$

Therefore, torque on the magnet, when it is normal to e field,

$$\tau = 1{\cdot}5 \times 0{\cdot}22 \sin 90° = 1{\cdot}5 \times 0{\cdot}22 \times 1$$

$$= \mathbf{0{\cdot}33\ N\ m}$$

ype F. On Magnetic moment of a current loop

Problem 3.10. A circular coil of 50 turns and radius 2 m carries a current of 12 A. Find (*a*) magnetic field at e centre of the coil and (*b*) magnetic moment associated ith it.

Sol. Here, $n = 50$; $a = 0{\cdot}2$ m and $I = 12$ A

(*a*) Now,
$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} = \frac{10^{-7} \times 2\pi \times 50 \times 12}{0{\cdot}2}$$

$$= 1{\cdot}885 \times 10^{-3}\ T$$

(*b*) Magnetic moment associated with the current carrying coil,

$$M = n\,I\,A = n\,I \times \pi a^2$$

$$= 50 \times 12 \times \pi \times (0{\cdot}2)^2 = \mathbf{75{\cdot}4\ A\ m^2}$$

Type G. On Magnetic moment of revolving electron

Problem 3.11. An electron in an atom revolves around the nucleus in an orbit of radius 0·53 Å. Calculate the equivalent magnetic moment, if the frequency of revolution of electron is $6{\cdot}8 \times 10^9$ MHz. *(C.B.S.E. 1998)*

Sol. Here, radius of the orbit of electron,

$$r = 0{\cdot}53\ Å = 0{\cdot}53 \times 10^{-10}\ m$$

Frequency of revolution of electron,

$$\nu = 6{\cdot}8 \times 10^9\ MHz = 6{\cdot}8 \times 10^{15}\ Hz$$

If *e* is the charge on electron and T is the time taken to complete one revolution, then the motion of electron equivalent to the current I given by

$$I = \frac{e}{T} = e\,\nu \qquad \left(\because \text{frequency} = \frac{1}{\text{time period}}\right)$$

The electron revolving in circular orbit behaves as a current loop and hence possesses magnetic moment given by

$$M = I\,A = e\,\nu \times \pi r^2 = \pi\,e\,\nu\,r^2$$

Since $e = 1{\cdot}6 \times 10^{-19}$ C,

$$M = \pi \times 1{\cdot}6 \times 10^{-19} \times 6{\cdot}8 \times 10^{15} \times (0{\cdot}53 \times 10^{-10})^2$$

$$= \mathbf{9{\cdot}6 \times 10^{-24}\ A\ m^2}$$

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & Curious Students

Problem 3.12. Each atom of an iron bar (having dimensions 5 cm × 1 cm × 1 cm) has a magnetic dipole oment of $1{\cdot}8 \times 10^{-23}$ Am². (*a*) What will be the magnetic oment of bar in the state of magnetic saturation ? (*b*) What ill be torque required to place this magnetised bar erpendicular to magnetic field of 15,000 G ? Given, density f iron = $7{\cdot}8 \times 10^3$ kg m^{-3}, atomic weight of iron = 56 and vogadro number, N = $6{\cdot}02 \times 10^{26}$ kg mol^{-1}.

Sol. Here, magnetic moment of one atom of iron,

$$M' = 1{\cdot}8 \times 10^{-23}\ A\ m^2$$

Volume of iron bar, $V = 5 \times 1 \times 1 = 5\ cm^3 = 5 \times 10^{-6}\ m^3$

Mass of iron bar, $m = V\rho = 5 \times 10^{-6} \times 7{\cdot}8 \times 10^3$

$$= 3{\cdot}9 \times 10^{-2}\ kg$$

Therefore, number of atoms in the iron bar,

$$n = \frac{N}{A} \times m = \frac{6{\cdot}02 \times 10^{26}}{56} \times 3{\cdot}9 \times 10^{-2}$$

$$= 4{\cdot}19 \times 10^{23}$$

(*a*) In the state of magnetic saturation, all the atomic agnets will align themselves in the same direction and then, e magnetic moment of iron bar will become

$$M = M' \times n = 1{\cdot}8 \times 10^{-23} \times 4{\cdot}19 \times 10^{23}$$

$$= 7{\cdot}54\ A\ m^2$$

(*b*) Here, $B = 15{,}000\ G = 1{\cdot}5\ T$ and $\theta = 90°$

The required torque,

$$\tau = M\,B \sin\theta = 7{\cdot}54 \times 1{\cdot}5 \sin 90°$$

$$= 11{\cdot}31\ N\ m$$

Problem 3.13. A magnetic dipole is under the influence of two magnetic fields B_1 and B_2 [Fig. 3.19]. The angle etween the field directions is 60° and one of the fields has magnitude of $1{\cdot}2 \times 10^{-2}$ T. If the dipole comes to stable equilibrium at an angle of 15° with this field, what is the magnitude of the other field ? *(Text Problem)*

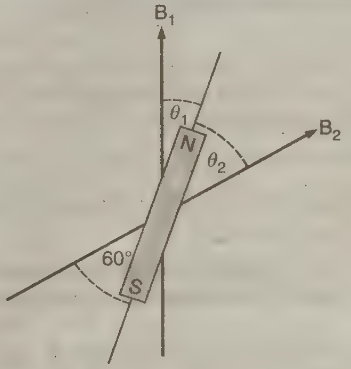

Fig. 3.19

Sol. Here, $B_1 = 1{\cdot}2 \times 10^{-2}$ T ;

Inclination of dipole with B_1, $\theta_1 = 15°$

Therefore, inclination of dipole with B_2,

$$\theta_2 = 60° - 15° = 45°$$

As the dipole is in equilibrium ; the torque on the dipole due to the field B_1 is equal and opposite to that due to B_2. If M is magnetic dipole moment of the dipole, then

$$M\,B_1 \sin\theta_1 = M\,B_2 \sin\theta_2$$

or
$$B_2 = \frac{B_1 \sin\theta_1}{\sin\theta_2} = \frac{1{\cdot}2 \times 10^{-2} \sin 15°}{\sin 45°}$$

$$= \frac{1{\cdot}2 \times 10^{-2} \times 0{\cdot}2588}{0{\cdot}707} = \mathbf{4{\cdot}39 \times 10^{-3}\ T}$$

Problem 3.14. A closely wound solenoid of 1000 turns and area of cross-section $2{\cdot}0 \times 10^{-4}$ m² carries a current

of 2·0 A. It is placed with its horizontal axis at 30°with the direction of a uniform horizontal magnetic field of 0·16 T as shown in Fig. 3.20.

(*a*) What is the torque experienced by the solenoid due to the field ?

(*b*) If the solenoid is free to turn about the vertical direction, specify its orientations of stable and unstable equilibrium. What is the amount of work needed to displace the solenoid from its stable orientation to its unstable orientation ? (*Text Problem*)

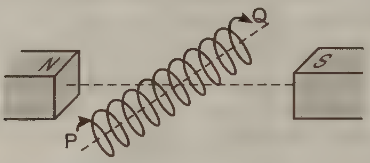

Fig. 3.20

Sol. Here, number of turns = 1000 ;

$$I = 2{\cdot}0\ \text{A} ; A = 2{\cdot}0 \times 10^{-4}\ \text{m}^2 ;$$

The magnetic moment of the solenoid,

$$M = (I\,A) \times \text{number of turns}$$
$$= 2{\cdot}0 \times 2{\cdot}0 \times 10^{-4} \times 1000$$
$$= 0{\cdot}4\ \text{A m}^2$$

(*a*) Now, $\tau = M\,B \sin\theta$

Here, $B = 0{\cdot}16$ T, $\theta = 30°$

$\therefore$ $\tau = 0{\cdot}4 \times 0{\cdot}16 \times \sin 30° = \mathbf{0{\cdot}032\ N\ m}$

(*b*) The solenoid will be in ***stable equilibrium***, when $\vec{M}$ *i* *parallel* $\vec{B}$ *(θ = 0°) and it will be in* ***unstable equilibrium***, *whe* $\vec{M}$ *is antiparallel* $\vec{B}$ (θ = 180°).

Now, $W = M\,B\,(\cos\theta_1 - \cos\theta_2)$

Therefore, work done to displace the solenoid fro stable orientation to unstable orientation,

$$W = M\,B\,(\cos 0° - \cos 180°) = 2\,M\,B = 2 \times 0{\cdot}4 \times 0{\cdot}1$$
$$= \mathbf{0{\cdot}128\ J}$$

FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 3.01. What is a magnet ? (*P.S.S.C.E. 2002*)

Ans. A magnet is an arrangement of two equal and opposite magnetic poles separated by certain distance. The attractive and directive are two main properties of a magnet.

Q. 3.02. What do you mean by directive property of a magnetic dipole ?

Ans. A freely suspended magnet always aligns itself along the N-S line.

Q. 3.03 What happens to dipole moment, if a bar magnet is cut into two equal pieces parallel to its length ? (*H.P.S.S.C.E. 2002*)

Ans. Let m and $2\,l$ be pole strength and length of the given bar magnet. When the magnet is cut into two equal pieces parallel to its length, each piece will be a magnet having length $2\,l$ (unchanged) and pole strength $\frac{m}{2}$. Therefore, magnetic moment of each piece will be $\frac{m}{2}(2\,l) = m\,l$ *i.e.* one half of that of original magnet.

Q. 3.04. A bar magnet is cut into two equal pieces transverse to its length. What happens to its dipole moment ? (*H.S.S.C.E. 2002*)

Ans. Let m and $2\,l$ be pole strength and length of the given bar magnet. When the magnet is cut into two equal pieces transverse to its length, each piece will be a magnet having pole strength m (unchanged) and length l. Therefore, magnetic moment of each piece will be $m\,l$ *i.e.* one half of that of original magnet.

Q. 3.05. Why ordinarily a piece of iron does not behave as a magnet ?

Ans. In an ordinary piece of iron, the molecular magnets are randomly oriented and form closed chains. Since the molecular magnets cancel the effect of each other, the ordinary iron piece does not behave as a magnet.

Q. 3.06. What is the source of magnetic field (magnetism) ? (*P.S.S.C.E. 1999 S*)

Ans. Magnetism is of electrical origin. The electrons revolving in an atom behave as tiny current loops and these current loops give rise to magnetism.

Q. 3.07. Does an isolate magnetic pole exist like an isolate electric charge ?

Ans. No, an isolate magnetic pole does not exist.

Q. 3.08. What is the unit of magnetic pole strength ?

Ans. Unit of magnetic pole strength : ampere metre (Am

Q. 3.09. Define the term magnetic dipole moment. (*H.S.S.C.E. 2002 ; C.B.S.E. 1995*

Ans. Refer to section 3.05.

Q. 3.10. What is the unit of magnetic dipole moment

Ans. Unit of magnetic dipole moment : ampere metre (A m^2).

Q. 3.11. What is the direction of magnetic dipol moment ? (*H.S.S.C.E. 2002*

Ans. It is from S-pole to N-pole of the magnetic dipole

Q. 3.12. What is the basic difference between magneti lines of force and electric lines of force ? (*H.S.S.C.E. 1994*

Ans. The electric lines of force originate from positiv charge and end at negative charge and are thus discontinuou curves. But as isolated magnetic poles do not exist, th magnetic field lines are closed loops.

Q.3.13. Why two magnetic lines of force donot cros each other ? (*P.S.S.C.E. 1999*

Ans. Two magnetic field lines can not intersect eac other. It is because, if they do so, then at the point o intersection, the magnetic field will have two directions alon the tangents to the two field lines.

Q. 3.14. What is the torque experienced by a magneti dipole of magnetic moment M placed with its axis at a angle ϑ with a uniform external magnetic field B ? (*I.S.C.E. 1993*

Ans. Torque on the dipole, $\tau = M\,B \sin\theta$

Q. 3.15. A short bar magnet placed with its axis makin an angle θ with a uniform external field B experiences torque. What is the magnetic moment of the magnet ? (*C.B.S.E. 1990*

Ans. Torque on a dipole, $\tau = M\,B \sin\theta$

$$\therefore \qquad M = \frac{\tau}{B \sin\theta}$$

Q. 3.16. Does a bar magnet exert a torque on itself due o its own field ? Does one element of a current-carrying vire exert a force on another element of the same wire ? *(Text Question)*

Ans. No, a bar magnet does not exert a force or torque n itself due to its own field.

But an element of a current carrying conductor xperiences force due to another element of the conductor.

Q. 3.17. A bar magnet is stationary in magnetic meriian. Another similar magnet is kept parallel to it, such that he centres lie on their perpendicular bisectors. If the econd magnet is free to move, then what type of motion t will have : translatory, rotatory or both ? *(I.I.T. 1977)*

Ans. There will be only translatory motion. It can be hown by finding the net forces on the two poles of the second nagnet due to the poles of the first by drawing a vector liagram.

Q. 3.18. When does a magnetic dipole possess maxinum potential energy inside a magnetic field ?

Ans. A magnetic dipole possesses maximum potential nergy, when its magnetic moment $\vec{M}$ and magnetic ield $\vec{B}$ are antiparallel.

Q. 3.19. Can a current loop be treated as magnetic lipole ?

Ans. A current loop can be treated as a magnetic dipole. f the current loop has area A and carries current I, then its magnetic dipole moment is given by

$$M = I A$$

Q. 3.20. Compare the magnetic fields due to a straight solenoid and a bar magnet. *(P.S.S.C.E. 1996 S, 1994)*

Ans. The magnetic field of a bar magnet and a straight solenoid are identical. The two ends of the straight solenoid behave as the north and south poles as in case of a bar magnet.

Q. 3.21. Define Bohr magneton and write its value. *(P.S.S.C.E. 1999 S)*

Ans. *Bohr magneton is defined as the magnetic dipole moment associated with an atom due to orbital motion of an electron in the first orbit of hydrogen atom.*

Bohr magneton, $\mu_B = 9{\cdot}27 \times 10^{-24}$ A m^2

Q. 3.22. What is the magnetic moment of an electron due to its orbital motion ?

Ans. Magnetic moment of electron due to its orbital motion,

$$M = n\left(\frac{e\,h}{4\,\pi\,m_e}\right),$$

where the letters have their usual meanings.

Q. 3.23. Find out the value of 1 Bohr magneton. Given $h = 6{\cdot}62 \times 10^{-34}$ J s, $e = 1{\cdot}6 \times 10^{-19}$ C and $m_e = 9{\cdot}1 \times 10^{-31}$ kg. *(H.S.S.C.E. 2001)*

Ans. 1 Bohr magneton

$$= \frac{e\,h}{4\,\pi\,m_e} = \frac{1{\cdot}6\times10^{-19}\times6{\cdot}62\times10^{-34}}{4\,\pi\times9{\cdot}1\times10^{-31}}$$

$$= 9{\cdot}27 \times 10^{-24} \text{ A m}^2$$

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 3.01. What happens, if a bar magnet is cut into wo equal pieces *(i)* transverse to its length *(ii)* along its ength ? *(Text Question)*

Ans. In both the cases, one will get two magnets. If the nagnet has a pole strength m, length $2\,l$ and magnetic noment M, then pole strength, length and magnetic moment n case *(i)* will be m, l and $\frac{M}{2}$; while in case *(ii)*, the orresponding values will be $\frac{m}{2}$, $2\,l$ and $\frac{M}{2}$.

Also refer to VSQ 3.03 and 3.04.

Q. 3.02. State four properties of bar magnet. *(P.S.S.C.E. 2002)*

Ans. Refer to section 3.04.

Q. 3.03. You are given two identical looking bars A and 3. One of these is a bar magnet and the other an ordinary piece of iron. Give an experiment to identify, which one of he two is a bar magnet. You are not to use any additional naterials for the experiment. *(H.P.S.S.C.E. 2001 ; C.B.S.E. 1998)*

Or

Two identical looking iron bars, A and B are given, one of which is definitely known to be magnetised. How would one ascertain, whether or not both are magnetised ? If only one is magnetised, how does one ascertain which one ? Using nothing else, but the two bars A and B). *(I.I.T. 1982 ; Text Question)*

Ans. If on bringing different ends of the two bars close o each other, they produce repulsion in some case, then both he iron bars are magnetised. Otherwise, one bar is nagnetised and the other is simply iron bar. To find out which one is magnetised, call one bar as A and the other as B. Place bar B on table. Bring one end of bar A close to the one end of bar B. The bar A will experience attraction. Now, move the bar A to the middle of bar B. If A experiences no force, then A is iron bar and B is magnetised. On the other hand, if bar A experiences force, then A is magnetised and B is iron bar.

Q. 3.04. A steel wire of length l has a magnetic moment M. It is then bent into a semicircular arc. What is the new magnetic moment ? *(N.C.E.R.T. 1975)*

Ans. If m is pole strength, then

$$m = \frac{M}{l}$$

When the wire is bent into a semicircular arc, the separation between the two poles changes from l to $2\,r$, where r is radius of the semicircular arc. Since $l = \pi\,r$ or $r = \frac{l}{\pi}$, the new magnetic moment of the steel wire,

$$M' = m \times 2\,r = \frac{M}{l} \times \frac{2\,l}{\pi} = \frac{2\,M}{\pi}$$

Q. 3.05. Magnetic lines of force should better be called as field lines. Explain.

Ans. It is misleading to call magnetic field lines as magnetic lines of force. To elaborate, consider the expression for magnetic Lorentz force :

$$\vec{F}_m = q\,(\vec{v} \times \vec{B})$$

The magnetic force $\vec{F}_m$ is perpendicular to magnetic field $\vec{B}$ *i.e.* magnetic force is not along the direction of magnetic field. Hence, magnetic lines of force should be called only as magnetic field lines.

Q. 3.06. Define magnetic dipole moment of a magnet and write its unit by taking into consideration the torque acting on it, when placed in magnetic field. *(H.P.S.S.C.E. 1998)*

Ans. We know, $\tau = M\,B \sin\theta$

If $B = 1$ and $\theta = 90°$, then $\tau = M \times 1 \sin 90° = M \times 1 \times 1$

or $M = \tau$

Hence, the magnetic moment of a magnet is numerically equal to the torque acting on the magnet, when placed perpendicular to the direction of a uniform magnetic field of unit strength.

Again, $M = \dfrac{\tau}{B \sin\theta}$

Therefore, unit of magnetic dipole moment

$$= \frac{\text{newton metre}}{\text{tesla}} = \mathbf{N\,m\,T^{-1}}$$

Q. 3.07. Define magnetic dipole moment of a magnet by taking into consideration the torque acting on it, when placed in magnetic field. Is it a vector or a scalar ? *(H.S.S.C.E. 1992)*

Ans. For definition of magnetic dipole moment, refer to section 3.10.

Magnetic dipole moment is a vector.

Q. 3.08. A magnetised needle in a uniform magnetic field experiences a torque but no net force. An iron nail near a bar magnet, however, experiences a force of attraction in addition to a torque. Why ? *(C.B.S.E. 2001 S ; Text Question)*

Ans. The force and torque act on the nail due to the induced magnetic moment acquired by it. The iron needle also will not experience any force, if magnetic field is uniform. The magnetic field due to a bar magnet is not uniform. Therefore, an iron nail experiences both a force and torque, when placed near a bar magnet.

It may be pointed that the nail experiences a net attractive force. It is because the attractive force on the near induced pole of the nail is greater than the repulsive force on the far induced pole.

Q. 3.09. Why does a magnetic dipole possess potential energy, when placed at some inclination with the direction of the field ?

Ans. In equilibrium, a magnetic dipole always align itself along the direction of magnetic field. When the magneti dipole is displaced from the equilibrium position, a restorin torque acts on the dipole to bring it back. Therefore, to plac the dipole at some inclination with the field, work has to b done against the restoring torque. This work done is store in the dipole as its potential energy.

Q. 3.10. A magnetic dipole is free to rotate in a uniforn magnetic field. For what orientation of the magnet w.r.t. th magnetic field, (*a*) torque is maximum, (*b*) potential energ is maximum (*c*) rate of change of torque with angle o orientation is maximum ?

Ans. (*a*) We know, $\tau = M\,B \sin\theta$

Therefore, torque on the dipole will be maximum, whe $\sin\theta$ is maximum *i.e.* equal to 1 or θ = **90°.**

(*b*) Also, $U = -M\,B \cos\theta$

The maximum value of potential energy of the dipole i equal to M B. Therefore, potential energy of the dipole wil be maximum, when $\cos\theta$ is equal to – 1. *i.e.* θ = **180°.**

Now, rate of change of torque with angle of orientation

$$\frac{d\tau}{d\theta} = \frac{d}{d\theta}(M\,B \sin\theta) = M\,B \cos\theta$$

Therefore, $\dfrac{d\tau}{d\theta}$ will be maximum, when $\cos\theta$ i maximum *i.e.* equal to 1 or $\theta = 0°$

Q. 3.11. A bar magnet of magnetic moment M i aligned parallel to the direction of a uniform magnetic fiel B. What is the work done to turn the magnet, so as to alig its magnetic moment (*i*) opposite to the field direction an (*ii*) normal to the field direction ? *(C.B.S.E. 2001*

Ans. The work done to rotate a bar magnet from it initial position $\theta = \theta_1$ to the final position $\theta = \theta_2$ is given by

$W = M\,B\,(\cos\theta_1 - \cos\theta_2)$,

where θ is angle, which magnet (or M) makes with th direction of magnetic field (B).

(*i*) Here, $\theta_1 = 0°$ and $\theta_2 = 180°$

$\therefore\ W = M\,B\,(\cos 0° - \cos 180°) = M\,B = [1 - (-1)] = \mathbf{2\,M}$

(*ii*) Here, $\theta_1 = 0°$ and $\theta_2 = 90°$

$\therefore\ W = M\,B\,(\cos 0° - \cos 90°) = M\,B\,[1 - 0] = \mathbf{M\,B}$

abc TECHIE STUFF – CONCEPTUAL SHORT ANSWER QUESTIONS

For ambitious, brilliant & curious Students

Q. 3.01. An unmagnetised piece of iron is attracted to a bar magnet. Explain the origin of this attractive force. *(Roorkee, 1980)*

Ans. An atom is equivalent to a current loop and hence behaves as a tiny magnet. In an unmagnetised piece of iron (or in the absence of an external magnetising field), these current loops are so oriented that the iron piece does not have any net magnetism.

When unmagnetised iron piece is brought near the bar magnet, the current loops located at the ends of the bar magnet and the iron piece facing each other align themselves. When they do so, the currents in the current loops happen to be in the same direction and as a consequence, the attractive force occurs between the two.

Q. 3.02. Must every magnetic field configuration have a north pole and a south pole ? What about the field due to a toroid ? *(Text Question)*

Ans. It is not necessary that every magnetic fiel configuration must have a north pole and a south pole. Th poles exist only, if the source has a net non-zero magneti moment.

A toroid and infinite straight conductor do not hav north and south poles.

Q. 3.03. Can you think of a magnetic field configu ration with three poles ? *(Text Question*

Ans. Magnetic poles always occur in pairs. However, tw bar magnets can be arranged to produce a magnetic fiel configuration of three poles. It can be done by putting nort poles or south poles of the two magnets together.

Q. 3.04. Magnetic field arises due to charges in motion Can a system have magnetic moment, even though it net charge is zero ? *(Text Question*

Ans. A system can have a magnetic moment eve though its net charge is zero. It is because, the average charg of a system may be zero, but it is not necessary that magnetic moments due to various current loops will also be zero. For example, a neutron has zero charge, but possesses non-zero magnetic moment.

Q. 3.05. An iron bar is magnetised with the help of another magnet or by subjecting it to a magnetising field. The magnetism acquired by the magnet is assumed due to the alignment of molecular magnets. Does the length of the iron bar undergo a change during the magnetisation process ?

Ans. Yes, the length of the iron bar increases in the direction of magnetisation. This effect is called ***magnetostriction*** and is used for producing ultrasonic waves.

Q. 3.06. Magnetic field lines show the direction (at every point), which a small magnetised needle takes up (at the point). Do the magnetic field lines also represent `the lines of force' on a moving charged particle at every point ? *(Text Question)*

Ans. Force on a charged particle moving in a magnetic field is given by

$$\vec{F}_m = e(\vec{v} \times \vec{B})$$

Therefore, force $\vec{F}$ is always normal to $\vec{B}$ *i.e.* lines of force on a moving charged particle are normal to the magnetic field lines. Hence, the lines of force do not represent magnetic field lines.

Q. 3.07. If a magnetic needle is secured to a cork and the cork is floated on water, the terrestrial magnetic field will cause the needle to turn and set itself along the magnetic meridian, but the needle will not move northwards or southwards. If a bar magnet is placed near the needle, the needle will set itself in the direction of the lines of force and will begin to move toward the magnet. What are the reasons for the different behaviour of the needle in the magnetic fields of the earth and the magnet ?

Ans. In the region of the dimensions of the magnetic needle, the magnetic field of earth is practically uniform *i.e.* its intensity remains constant both in magnitude and direction. For this reason, the magnetic field of earth produces only a torque and no net force on the magnetic needle. As a result, the magnetic needle sets itself along the magnetic meridian and does not move northwards or southwards.

In the region of the dimensions of the magnetic needle, the magnetic field of the magnet is heterogeneous. The intensity of the magnetic field of the magnet at one end of the magnetic needle is stronger than that at the other. As a result, the magnetic field of the magnet exerts a torque and a net resultant force on the magnetic needle. The torque on the needle makes it to set in magnetic meridian and the resultant force produces translational motion.

Q. 3.08. The poles of a magnet cannot be separated. How does this statement derive support from the magnetic dipole bahaviour of a current loop ?

Ans. A current loop behaves as a magnetic dipole. Its one face behaves as *n*-pole, while the other as *s*-pole. As the two faces of the current loop cannot be separated from each other, it follows that the magnetic poles developed on the two faces also cannot be separated from each other.

Q. 3.09. Magnetic field lines can be entirely confined within the core of a toroid, but not within a straight solenoid. Why ? *(Text Question)*

Ans. If the field lines were entirely confined between the two ends of a straight solenoid, the flux through the cross-section of the solenoid at each end would be non-zero. But the flux of a field through any closed surface must always be zero. Since toroid has no ends, it can entirely confine the field in its core.

Q. 3.10. An electron in the ground state of hydrogen atom is revolving in anticlockwise direction in a circular orbit. The atom is placed in uniform magnetic induction $\vec{B}$, such that the plane normal to the electron orbit makes an angle of 30° in the magnetic induction. Find the torque experienced by the orbiting electron.

(I.I.T. 1996)

Ans. The magnetic moment of the electron in an hydrogen atom is given by

$$M = \frac{e\,h}{4\pi m_e}$$

The magnetic moment vector of the electron is directed along normal to the plane of the electron orbit.

When the atom is placed in magnetic field $\vec{B}$, such that plane normal to the electron orbit *i.e.* magnetic moment vector of the electron makes an angle of 30° with the magnetic induction $\vec{B}$, the magnitude of the torque experienced by the orbiting electron is given by

$$\tau = |M\,B \sin 30°| = \frac{e\,h}{4\pi m_e} B \times \frac{1}{2} = \frac{e\,h}{8\pi m_e} B$$

Q. 3.11. Two particles, each of mass *m* and charge *q* are attached to the two ends of a light rigid rod of length 2 R. The rod is rotated at constant angular speed about a perpendicular axis passing through its centre. Find the ratio of the magnetic moment of the system and its angular momentum about the axis through the centre of the rod.

(I.I.T. 1998)

Ans. Suppose that the rod is rotated at constant angular speed ω about the perpendicular axis ZZ′ through its centre [Fig. 3.21].

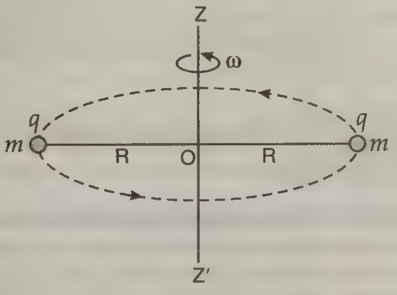

Fig. 3.21

Angular momentum of the system of two particles about ZZ′,

$$L = m R^2 \omega + m R^2 \omega = 2\,m R^2 \omega$$

When the rod is rotated, the two charged particles move along a circular path of radius R with linear speed R ω. If T is period of revolution of the rod, then a charge equal to q crosses any point on the circular path after a time,

$$t = \frac{T}{2} = \frac{1}{2}\left(\frac{2\pi}{\omega}\right) = \frac{\pi}{\omega}$$

Thus, rotational motion of the charged particles is equivalent to current,

$$I = \frac{q}{t} = \frac{q}{\pi / \omega} = \frac{q\,\omega}{\pi}$$

Therefore, magnetic moment of the system,

$$M = I\,A = \frac{q\,\omega}{\pi} \times \pi\,R^2 = q\,R^2\,\omega$$

Hence $$\frac{M}{L} = \frac{q\,R^2\,\omega}{2\,m\,R^2\,\omega} = \frac{q}{2\,m}$$

Q. 3.12. If magnetic monopoles existed, how would Gauss's law of magnetism be modified ?

(Text Question)

Ans. Gauss's law of magnetism states that the flux through any closed surface is always zero. If monopole existed, then $\oint_S \vec{B} \cdot d\vec{S}$ would not be zero but it would be equal to the magnetic flux due to monopole enclosed by the closed surface.

FAQs FREQUENTLY ASKED SHORT ANSWER QUESTIONS

Carrying 3 Marks

1. List the main properties of a magnet.
2. Explain the magnetism on the basis of atomic theory.
3. What is magnetic pole ? Express mathematically the force between two magnetic poles placed a finite distance apart. Hence, define unit magnetic pole strength.
4. What is a magnetic dipole ? Define magnetic dipole moment. Give its S.I. unit.
5. What are magnetic field lines ? Give their important properties. *(H.S.S.C.E. 1994)*
6. Derive an expression for the magnetic field due to a magnetic dipole in broad-side on position at a distance *r* from its centre. The length of the dipole is 2 *l* and its magnetic moment is M. *(I.S.C.E. 1998)*
7. Obtain an expression for the torque acting on a magnetic dipole placed in a magnetic field $\vec{B}$, making an angle θ with the field. *(H.P.S.S.C.E. 2000)*
8. Derive an expression for the torque experienced by a magnetic dipole in a uniform magnetic field and hence define magnetic dipole moment. *(H.P.S.S.C.E. 1996)*
9. Derive an expression for torque acting on a bar magnet held at an angle with the direction of the uniform magnetic field. *(H.S.S.C.E. 1992)*
10. Derive expression for potential energy of a bar magnet, when placed in a uniform magnetic field. *(P.S.S.C.E. 2001 ; H.P.S.S.C.E. 1998 S)*
11. A current loop behaves as a magnetic dipole. Obtain expression for magnetic dipole moment of a current loop.
12. In a hydrogen atom, an electron of charge *e* revolves in an orbit of radius *r* with a speed *v*. Prove that the magnetic moment associated with the electron is given by $\frac{e\,v\,r}{2}$. *(C.B.S.E. 2002)*
13. Derive an expression for the magnetic dipole moment of an atom. *(H.P.S.S.C.E. 1999 S)*
14. Explain how does an atom behave as magnetic dipole. Derive an expression for its magnetic dipole moment.

FAQs FREQUENTLY ASKED LONG ANSWER QUESTIONS

Carrying 5 Marks

1. What is a magnetic dipole ? Obtain expression for the strength of magnetic field at a point at distance *r* from its centre on (*i*) axial line and (*ii*) equitorial line. Find the strength of the field in special case, when the length of the magnet is very small as compared to the distance *r*.
2. (*a*) Derive an expression for the torque acting on a bar magnet, when placed at an angle θ with the direction of the uniform magnetic field. Hence define magnetic dipole moment of the magnet.
   (*b*) Find the amount of work done in rotating a magnet through angle θ against the torque acting due to uniform magnetic field. What happens to the work done ?
3. (*a*) Derive an expression for the torque acting on a bar magnet placed in the uniform magnetic field.
   (*b*) Compare the magnetic fields of a bar magnet and current carrying solenoid. *(P.S.S.C.E. 2001)*
4. Explain how does an atom behave as magnetic dipole. Derive an expression for the magnetic dipole moment of the atom. Also define Bohr magneton. *(P.S.S.C.E. 2001)*

FAQs FREQUENTLY ASKED NUMERICAL PROBLEMS

For Practice

Type A. On Force between Magnetic poles

1. Two magnetic poles, one of which is four times stronger than the other exert a force of 5 gf on each other, when placed at distance of 10 cm in air. Find the strength of each pole. **[Ans. 35 A m, 140 A m]**
2. Two like magnetic poles of strength 25 A m and 64 A m are situated 1·0 m apart in air. At what point on the line, joining the two poles, the magnetic field will be zero ?
   [Ans. Either at 0·385 m from pole of 25 A m (towards 64 A m) or at 1·667 m from pole of 25 A m (on the other side of 64 A m)]
3. Two identical magnets with a length 10 cm and weight 50 gf each are arranged freely wih their like poles facing in a vertical glass tube [Fig. 3.22]. The upper magnet hangs in the air above the lower one so that the distance between the nearest poles of the magnets is 3 mm. Determine the pole strength of the poles of these magnets. **[Ans. 6·64 A m]**

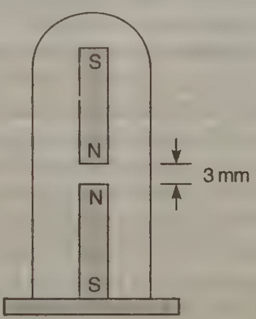

Fig. 3.22

Type B. On Magnetic moment of a Bar Magnet

4. A magnetised steel wire 31·4 cm long has a pole strength of 0·2 A m. It is then bent in the form of a semicircle. Calculate the magnetic moment of this needle.
[**Ans.** 0·04 A m^2]

5. Two thin bar magnets of pole strengths 4 A m and 7 A m respectively and lengths 0·21 m and 0·12 m respectively are placed at right angles to each other with the N-pole of the first touching the S-pole of the second. Find the magnetic moment of the system. [**Ans.** 1·19 A m^2]

Type C. On Magnetic field due to a Bar magnet

6. A bar magnet is 0·1 m long and has a pole strength of 10 A m. Calculate the magnetic field at a distance of 0·2 m from its centre at a point (*i*) on its axis and (*ii*) on its right bisector through the centre.
[**Ans.** (*a*) $2{\cdot}84 \times 10^{-5}$ T ; (*b*)$1{\cdot}14 \times 10^{-5}$ T]

7. A short bar magnet has a magnetic moment of 0·48 J T^{-1}. Give the direction and magnitude of the magnetic field produced by the magnet at a distance of 10 cm from the centre of the magnet on (*i*) the axis (*ii*) the equitorial line of the magnet. (*Text Problem*)
[**Ans.** $9{\cdot}6 \times 10^{-5}$ T (parallel to $\vec{M}$),
$4{\cdot}8 \times 10^{-5}$ T (opposite to $\vec{M}$)]

8. Two short bar magnets of magnetic moments 96 A m^2 and 81 A m^2 are placed along mutually perpendicular straight lines meeting at a point P. Find the magnetic field at point P, if it lies at distances of 0·4 m and 0·3 m respectively from the centres of the two magnets. [**Ans.** $6{\cdot}7 \times 10^{-4}$ T]

9. Two short bar magnets $N_1 S_1$ and $N_2 S_2$ of magnetic moments 32 A m^2 and 27 A m^2 are placed on the table as shown in Fig. 3.23. Find the magnitude and direction of the magnetic fields produced by these magnets at point P located on equitorial lines of both the magnets at distances of 0·4 m and 0·3 m respectively from their centres.
[**Ans.** $1{\cdot}12 \times 10^{-4}$ T (making an angle of 63·4° with N_1S_1)

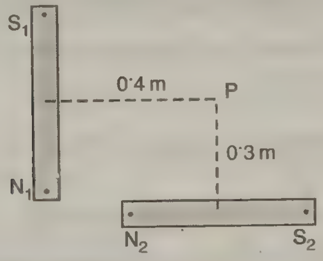

Fig. 3.23

Type D. On Torque on a Bar magnet

10. A short bar magnet placed with its axis at 30° with a uniform external magnetic field of 0·25 T experiences a torque of magnitude equal to $4{\cdot}5 \times 10^{-2}$ J. What is the magnitude of magnetic moment of the magnet?
(*Text Problem*) [**Ans.** 0·36A m^2]

11. A magnetised needle of magnetic moment $4{\cdot}8 \times 10^{-2}$ J T^{-1} is placed at 30° with the direction of uniform magnetic field of magnitude 3×10^{-2} T. Calculate the torque acting on the needle. (*C.B.S.E. 2001 S*) [**Ans.** $7{\cdot}2 \times 10^{-4}$ N m]

12. A short bar magnet of magnetic moment 0·9 J T^{-1} is placed with its axis at 60° to a uniform magnetic field. It experiences a torque of 0·063 N m. (*i*) Calculate the strength of the magnetic field and (*ii*) what orientation of the bar magnet corresponds to its equilibrium position in the magnetic field? (*C.B.S.E. 2000*)
[**Ans.** (*i*) 0·081 T (*ii*) when $\vec{M} \parallel \vec{B}$]

13. A closely wound solenoid of 2000 turns and area of cross-section $1{\cdot}6 \times 10^{-4}$ m^2, carrying a current of 4·0 A is suspended through its centre allowing it to turn in a horizontal plane.
(*a*) What is the magnetic moment associated with the solenoid?
(*b*) What is the force and torque on the solenoid, if a uniform horizontal magnetic field of $7{\cdot}5 \times 10^{-2}$ T is set up at an angle of 30° with the axis of the solenoid?
(*Text Problem*) [**Ans.** (*i*) 1·28 A m^2 (*ii*) 0, 0·048 N m]

14. A closely wound solenoid of 800 turns and area of cross-section $2{\cdot}5 \times 10^{-4}$ m^2 carries a current of 3·0 A. What is its associated magnetic moment? If the solenoid is free to turn about the vertical direction and a uniform horizontal magnetic field of 0·25 T is applied, what is the magnitude of torque on the solenoid, when its axis makes an angle of 30° with the direction of the applied field? (*Text Problem*)
[**Ans.** 0·6 A m^2 ; $7{\cdot}5 \times 10^{-2}$ N m]

Type E. On Potential energy of a Bar magnet

15. Calculate the work done in rotating a bar magnet of magnetic moment 3 J T^{-1} through an angle of 60° from its position along a magnetic field of strength $0{\cdot}34 \times 10^{-4}$ T.
[**Ans.** $5{\cdot}1 \times 10^{-5}$ J]

16. A circular coil of 100 turns and having an effective radius of 5 cm carries a current of 0·1 A. How much work is required to turn it in an external magnetic field of 1·5 Wb m^{-2} through 180° about an axis perpendicular to magnetic field. The plane of the coil is initially perpendicular to the magnetic field. (*Roorkee, 1986*)
[**Ans.** 0·2356 J]

17. A short bar magnet of magnetic moment 0·32 J T^{-1} is placed in a uniform external magnetic field of 0·15 T. If the bar is free to rotate in the plane of the field, which orientations would correspond to its (*i*) stable and (*ii*) unstable equilibrium? What is the potential energy of the magnet in each case? (*Text Problem*)
[**Ans.** (*i*) $\vec{M}$ parallel $\vec{B}$, $-4{\cdot}8 \times 10^{-2}$ J ;
(*ii*) $\vec{M}$ antiparallel $\vec{B}$, $4{\cdot}8 \times 10^{-2}$ J]

18. A short bar magnet placed with its axis at 30° with a uniform external magnetic field of 0·16T experiences a torque of magnitude 0·032 N m. (*a*) Estimate the magnetic moment of the magnet. (*b*) If the bar were free to rotate, which orientations would correspond to its (*i*) stable and (*ii*) unstable equilibrium? What is its potential energy in the field for cases (*i*) and (*ii*)?
[**Ans.** (*a*) 0·4 A m^2 ; (*b*) (*i*) $\vec{m}$ parallel $\vec{B}$, $-0{\cdot}064$ J
(*ii*) $\vec{m}$ antiparallel $\vec{B}$, $+0{\cdot}064$ J]

Type F. On Magnetic moment of a current loop

19. A planar loop of irregular shape enclosed an area of $7{\cdot}5 \times 10^{-4}$ m^2 and carries a current of 12 A. The sense of flow of current appears to be clockwise to an observer. What is the magnitude and direction of the magnetic moment vector associated with the current loop?
(*Text Problem*)
[**Ans.** 9×10^{-3} A m^2, normal to plane of loop and away from observer]

20. A circular coil of 300 turns and diameter 14 cm carries a current of 15 A. What is the magnitude of magnetic moment associated with the coil? (*Text Problem*)
[**Ans.** 69·3 A m^2]

Type C. On Magnetic moment of revolving electron

21. An electron in an atom revolves around the nucleus in an orbit of radius 0·5 Å. Calculate the equivalent magnetic moment, if the frequency of revolution of electron is 10^{10} MHz. *(C.B.S.E. 1998)* [**Ans.** $1\cdot26 \times 10^{-23}$ A m^2]

22. In a hydrogen atom, the electron moves in an orbit of radius 0·5 Å making 10^{16} r.p.s. Calculate the magnetic moment associated with the orbital motion of electron. *(I.I.T. 1988)* [**Ans.** $1\cdot26 \times 10^{-23}$ A m^2]

23. In hydrogen atom, an electron is making $6\cdot6 \times 10^{15}$ r.p.s. around the nucleus in an orbit of radius 0·523 Å. Calculate the equivalent magnetic dipole moment. *(C.B.S.E. 1992)* [**Ans.** $9\cdot07 \times 10^{-24}$ A m^2]

24. The electron in the hydrogen atom is moving with a speed of $2\cdot3 \times 10^6$ m s^{-1} in an orbit of radius 0·53 Å. Calculate the magnetic moment of the revolving electron. *(Roorkee, 1990)* [**Ans.** $9\cdot75 \times 10^{-24}$ A m^2]

MISCELLANEOUS PROBLEMS

25. Earth's magnetic field may be supposed to be due to a small bar magnet located at the centre of the earth. If the magnetic field at a point on the magnetic equator is 0·3 G, what is the magnetic moment of such a bar magnet? What is the magnetic field at the north pole? Given, radius of earth = $6\cdot4 \times 10^6$ m. *(I.I.T. 1973)* [**Ans.** $7\cdot864 \times 10^{22}$ A m^2, 0·6 G]

26. A short magnet of magnetic moment 2 A m^2 is lying in a horizontal plane with its north pole pointing 60° east of north. Find the net horizontal magnetic field at a point north of the magnet 0·2 m away from it. Horizontal component of earth's magnetic field = $0\cdot3 \times 10^{-4}$ T. *(Roorkee, 1991)* [**Ans.** $0\cdot59 \times 10^{-4}$ T, 21·48° west of north]

27. A bar magnet with poles 25 cm apart and pole strength 14·4 A m rests with its centre on a frictionless pivot. It is held in equilibrium at 60° to a uniform magnetic field of induction 0·25 T by applying a force F at right angle to its axis, 10 cm from its pivot. Calculate F? What will happen, if the force is removed? *(I.I.T. 1978)* [**Ans.** 6·24 N, the bar magnet will tend to align along the field]

28. Two small bar magnets each of magnetic moment 12·5 A m^2 are placed at the opposite corners A and C of the square ABCD as shown in Fig. 3.24. The length of the side of the square is 10 cm. Find the magnitude and direction of the magnetic field due to these magnets at the corners B and D.

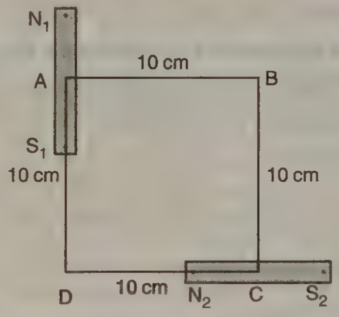

Fig. 3.24

[**Ans.** $1\cdot77 \times 10^{-3}$ T (making an angle of 45° with BC, $3\cdot54 \times 10^{-3}$ T making an angle of 45° with DA)

29. A small coil of radius 0·002 m is placed on the axis of a magnet of magnetic moment 10^5 J T^{-1} and length 0·1 m at a distance of 0·15 m from the centre of the magnet. The plane of the coil is perpendicular to the axis of the magnet. Find the force on the coil, when the current of 2·0 A is passed through it. *(Roorkee, 1989)* [**Ans.** $4\cdot4 \times 10^{-3}$ N]

SOLUTIONS/HINTS TO NUMERICAL PROBLEMS FOR PRACTICE

1. Here, F = 5 gf = 5×10^{-3} kgf = $5 \times 10^{-3} \times 9\cdot8$ N ;

r = 10 cm = 0·1 m

Let m and 4 m be strengths of two poles.

Now, $F = \dfrac{\mu_0}{4\pi} \cdot \dfrac{m \times 4m}{r^2}$

or $5 \times 10^{-3} \times 9\cdot8 = \dfrac{10^{-7} \times m \times 4m}{(0\cdot1)^2}$

or m = **35 A m** and $4m = 4 \times 35 =$ **140 A m**

2. Here, m_1 = 25 A m ; m_2 = 64 Am and r = 1·0 m

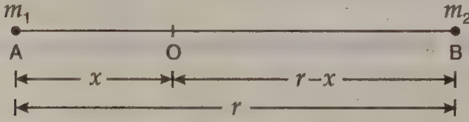

Fig. 3.25

Let magnetic field be zero at point O, such that AO = x.

Then, $\dfrac{\mu_0}{4\pi} \cdot \dfrac{m_1}{x^2} = \dfrac{\mu_0}{4\pi} \cdot \dfrac{m_2}{(r-x)^2}$ or $\dfrac{25}{x^2} = \dfrac{64}{(1\cdot0 - x)^2}$

or $64x^2 = 25(1\cdot0 - x)^2$ or $8x = \pm 5(1\cdot0 - x)$

or $8x = 5(1\cdot0 - x)$ or $-5(1\cdot0 - x)$

or x = **0·385 m** or **– 1·667 m**

3. Since length of the magnets is quite large as compared to separation between them, the interaction is effective only between their N-poles.

Let m be strength of the poles of the two magnets. Then,

$\dfrac{\mu_0}{4\pi} \cdot \dfrac{m \times m}{r^2}$ = weight of the magnet

Here, weight of the magnet = 50 gf = 50×10^{-3} kgf

$= 50 \times 10^{-3} \times 9\cdot8$ N

and r = 3 mm = 3×10^3 m

$\therefore \dfrac{10^{-7} \times m^2}{(3 \times 10^{-3})^2} = 50 \times 10^{-3} \times 9\cdot8$ or m = **6·64 A m**

4. Proceed as in SAQ 3.04.

5. $M_1 = 4 \times 0\cdot21 = 0\cdot84$ A m^2 and $M_2 = 7 \times 0\cdot12 = 0\cdot84$ A m^2

Let M be the magnetic moment of the combination of two magnets placed at right angles to each other. Then,

$M = \sqrt{M_1^2 + M_2^2} = \sqrt{(0\cdot84)^2 + (0\cdot84)^2} =$ **1·19 A m^2**

6. Proceed as in solved problem no. 3.04.

7. *(i)* $B_{axial} = \dfrac{\mu_0}{4\pi} \cdot \dfrac{2M}{r^3} = \dfrac{10^{-7} \times 2 \times 0\cdot48}{(10 \times 10^{-2})^3}$

$=$ **$9\cdot6 \times 10^{-5}$ T** **(parallel to $\vec{M}$)**

(ii) $B_{equi} = \dfrac{\mu_0}{4\pi} \cdot \dfrac{M}{r^3} = \dfrac{10^{-7} \times 0\cdot48}{(10 \times 10^{-2})^3}$

$=$ **$4\cdot8 \times 10^{-5}$ T** **(opposite to $\vec{M}$)**

8. The two magnets are placed as shown in Fig. 3.26 :

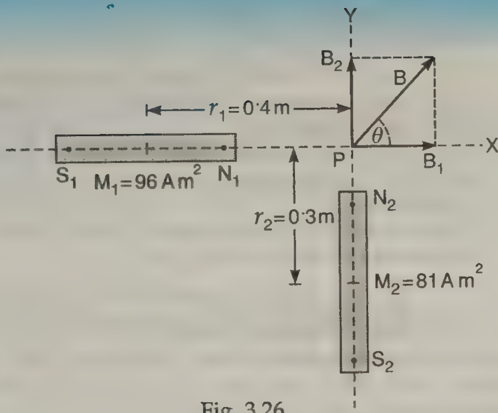

Fig. 3.26

The point P lies on axial line of both the magnets.

Let B_1 and B_2 be magnetic fields at point P due to the magnets $N_1 S_1$ and $N_2 S_2$ respectively. Then,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{2 M_1}{r_1^3} = \frac{10^{-7} \times 2 \times 96}{(0 \cdot 4)^3}$$

$$= 3 \times 10^{-4} \text{ T} \qquad \text{(along PX)}$$

and $$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2 M_2}{r_2^3} = \frac{10^{-7} \times 2 \times 81}{(0 \cdot 3)^3}$$

$$= 6 \times 10^{-4} \text{ T} \qquad \text{(along PY)}$$

Therefore, resultant magnetic field at point P,

$$B = \sqrt{B_1^2 + B_2^2} = \sqrt{(3 \times 10^{-4})^2 + (6 \times 10^{-4})^2} = \mathbf{6{\cdot}7 \times 10^{-4}\,T}$$

9. As shown in Fig. 3.27, the point P lies on the equitorial line of both the magnets.

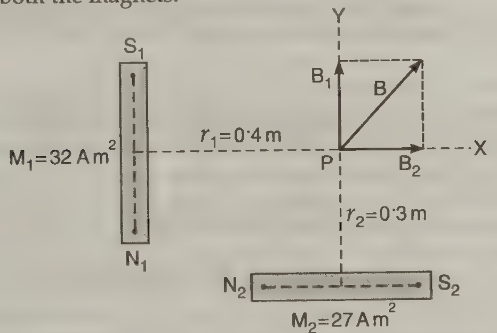

Fig. 3.27

Let B_1 and B_2 be magnetic fields at point P due to the magnets $N_1 S_1$ and $N_2 S_2$ respectively. Then,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{M_1}{r_1^3} = \frac{10^{-7} \times 32}{(0 \cdot 4)^3} = 0 \cdot 5 \times 10^{-4} \text{ T (along PY)}$$

and $$B_2 = \frac{\mu_0}{4\pi} \cdot \frac{M_2}{r_2^3} = \frac{10^{-7} \times 27}{(0 \cdot 3)^3} = 10^{-4} \text{ T (along PX)}$$

Therefore, resultant magnetic field at point P,

$$B = \sqrt{B_1^2 + B_2^2} = \sqrt{(0{\cdot}5 \times 10^{-4})^2 + (10^{-4})^2} = \mathbf{1{\cdot}12 \times 10^{-4}\,T}$$

If the direction of B makes an angle θ with the X-axis (or $N_1 S_1$), then

$$\tan\theta = \frac{B_2}{B_1} = \frac{10^{-4}}{0 \cdot 5 \times 10^{-4}} = 2 \qquad \text{or} \qquad \boldsymbol{\theta = 63{\cdot}4^\circ}$$

13. Proceed as in solved problem no. 3.14.
14. Proceed as in solved problem no. 3.14.
15. Proceed as in solved problem no. 3.09.
16. $M = n I A = 100 \times 0{\cdot}1 \times \pi \times (0{\cdot}05)^2 = 7{\cdot}854 \times 10^{-2}$ A m²

$W = M B (\cos\theta_1 - \cos\theta_2)$

$= 7{\cdot}854 \times 10^{-2} \times 1{\cdot}5 (\cos 0^\circ - \cos 180^\circ)$

$= 7{\cdot}854 \times 10^{-2} \times 1{\cdot}5 [1 - (-1)] = \mathbf{0{\cdot}2356\ J}$

17. (*i*) When $\vec{M}$ is parallel to $\vec{B}$, the magnet is in stable equilibrium.

$U = - M B = - 0{\cdot}32 \times 0{\cdot}15 = \mathbf{- 4{\cdot}8 \times 10^{-2}\ J}$

(*ii*) When $\vec{M}$ is antiparallel to $\vec{B}$, the magnet is in unstable equilibrium.

$U = M B = 0{\cdot}32 \times 0{\cdot}15 = \mathbf{4{\cdot}8 \times 10^{-2}\ J}$

18. (*a*) Proceed as in solved problem no. 3.06.
(*b*) Proceed as in problem no. 16.
19. $M = I A = 12 \times 7{\cdot}5 \times 10^{-4} = \mathbf{9 \times 10^{-3} A\ m^2}$

The direction of magnetic moment is perpendicular to the plane of the loop and away from the observer.

20. Proceed as in solved problem 3.10 (*b*).
21. Proceed as in solved problem 3.11.
22. Proceed as in solved problem 3.11.
23. Proceed as in solved problem 3.11.
24. Period of revolution of electron,

$$T = \frac{2\pi r}{v} = \frac{2\pi \times 0 \cdot 53 \times 10^{-10}}{2 \cdot 3 \times 10^6} = 1 \cdot 448 \times 10^{-16} \text{ s}$$

The orbital motion of electron is equivalent to current,

$$I = \frac{e}{T} = \frac{1 \cdot 6 \times 10^{-19}}{1 \cdot 448 \times 10^{-16}} = 1 \cdot 105 \times 10^{-3} \text{ A}$$

Therefore, magnetic moment of the revolving electron,

$M = I A = I \times \pi r^2 = 1{\cdot}105 \times 10^{-3} \times \pi \times (0{\cdot}53 \times 10^{-10})^2$

$= \mathbf{9{\cdot}75 \times 10^{-24}\ Am^2}$

25. A point on equator lies on the equitorial line of magnet and at a distance equal to radius of the earth. Therefore,

$B_{equi} = 0{\cdot}3\ \text{G} = 0{\cdot}3 \times 10^{-4}\ \text{T}\ ; r = 6{\cdot}4 \times 10^6$ m

For a short bar magnet,

$$B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{M}{r^3} \qquad \text{or} \qquad 0 \cdot 3 \times 10^{-4} = \frac{10^{-7} \times M}{(6 \cdot 4 \times 10^6)^3}$$

or $\quad \mathbf{M = 7{\cdot}864 \times 10^{22}\ A\ m^2}$

The point at the north pole of the earth lies on its axial line at a distance equal to radius of the earth.

For a short bar magnet,

$B_{axial} = 2\ B_{equi}$ (at the same distance)

$= \mathbf{2 \times 0{\cdot}3 = 0{\cdot}6\ G}$

26. The magnet NS of magnetic moment M is placed with its north pole pointing 60° east of north as shown in Fig. 3.28.

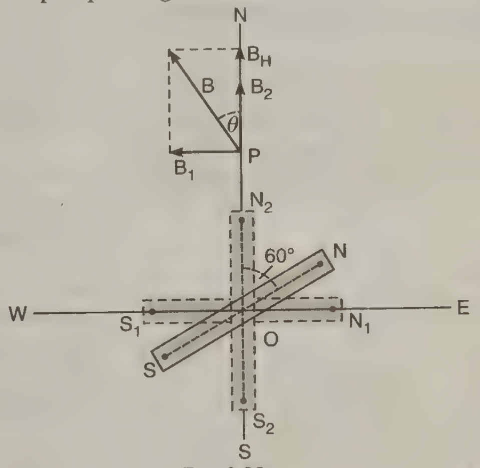

Fig. 3.28

The point P lies at a distance OP = 0·2 m north of the magnet.

Here, $M = 2\ A\ m^2$, $B_H = 0{\cdot}3 \times 10^{-4}\ T$

The magnetic moment M of the magnet NS can be resolved into two components :

(*i*) M sin 60° along EW-line and

(*ii*) M cos 60° along NS-line.

In other words, magnet NS of magnetic moment M placed 60° east of north can be replaced by two magnets N_1S_1 (of magnetic moment M sin 60° placed along EW-line) and N_2S_2 (of magnetic moment M cos 60° placed along NS-line). Let B_1 and B_2 be magnetic fields at point P due to magnets N_1S_1 and N_2S_2 respectively. Then,

$$B_1 = \frac{\mu_0}{4\pi} \cdot \frac{M \sin 60°}{(OP)^3} = \frac{10^{-7} \times 2 \times \sin 60°}{(0{\cdot}2)^3}$$

$$= 0{\cdot}2165 \times 10^{-4}\ T$$

$$\text{and } B_2 = \frac{\mu_0}{4\pi} \cdot \frac{2 M \cos 60°}{(OP)^3} = \frac{10^{-7} \times 2 \times 2 \times \cos 60°}{(0{\cdot}2)^3}$$

$$= 0{\cdot}25 \times 10^{-4}\ T$$

Resultant magnetic field at point P,

$$B = \sqrt{(B_1)^2 + (B_2 + B_H)^2}$$

$$= \sqrt{(0{\cdot}2165 \times 10^{-4})^2 + (0{\cdot}25 \times 10^{-4} + 0{\cdot}3 \times 10^{-4})^2}$$

$$= \mathbf{0{\cdot}59 \times 10^{-4}\ T}$$

Suppose that resultant magnetic field B is θ° west of north as shown in the figure. Then,

$$\tan\theta = \frac{B_1}{B_2 + B_H} = \frac{0{\cdot}2165 \times 10^{-4}}{0{\cdot}25 \times 10^{-4} + 0{\cdot}3 \times 10^{-4}} = 0{\cdot}3936$$

or $\theta = \mathbf{21{\cdot}48°}$ **(west of north)**

27. Here, $m = 14{\cdot}4$ A m ; $2\,l = 25$ cm $= 0{\cdot}25$ m, $B = 0{\cdot}25$ T

The magnet is held in equilibrium at 60° to the direction of magnetic field B by applying force F as shown in Fig. 3.29.

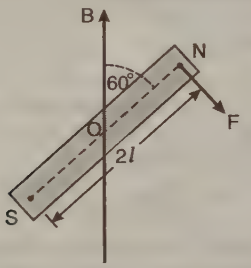

Fig. 3.29

For the equilibrium of the magnet,

$F \times ON = M\,B \sin\theta$ or $F \times l = (m \times 2\,l)\,B \sin 60°$

or $F = 2\,m\,B \sin 60° = 2 \times 14{\cdot}4 \times 0{\cdot}25 \times \sin 60° = \mathbf{6{\cdot}24\ N}$

If the force is removed, magnet will tend to align itsel along the magnetic field.

28. To find magnetic field at point B, proceed as in problem no. 9 and to find magnetic field at point B, proceed as in problem no. 8.

29. The circular coil carrying current is placed on the axis of the magnet as shown in Fig. 3.30.

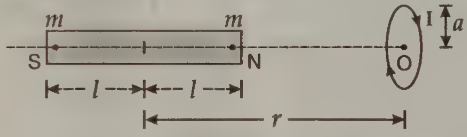

Fig. 3.30

Here, $a = 0{\cdot}002$ m, $I = 2$ A ; $2\,l = 0{\cdot}1$ m ; $r = 0{\cdot}15$ m and $M = 10^5\ J\ T^{-1}$

Therefore, pole strength of the magnet,

$$m = \frac{M}{2l} = \frac{10^5}{0{\cdot}1} = 10^6\ A\ m$$

Magnetic field at a distance *x* from the centre of a curren carrying coil of radius *a*,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi I a^2}{x^3} \qquad (a << x)$$

If B_1 and B_2 are magnetic fields due to the coil at north and south poles of the magnet, then force on the magnet due to coil,

$$F = m\,B_2 - m\,B_1$$

According to Newton's third law, magnet will exert an equal and opposite force on the coil. Therefore, force on the coil due to the magnet,

$$F = m\,B_1 - m\,B_2 = m\,(B_1 - B_2)$$

$$= m\left[\frac{\mu_0}{4\pi} \cdot \frac{2\pi I a^2}{(r-l)^3} - \frac{\mu_0}{4\pi} \cdot \frac{2\pi I a^2}{(r+l)^3}\right]$$

$$= \frac{\mu_0}{4\pi} \cdot 2\pi I a^2 m \left[\frac{1}{(r-l)^3} - \frac{1}{(r+l)^3}\right]$$

$$= 10^{-7} \times 2\pi \times 2 \times (0{\cdot}002)^2 \times 10^6$$

$$\times \left[\frac{1}{(0{\cdot}15 - 0{\cdot}05)^3} - \frac{1}{(0{\cdot}15 + 0{\cdot}05)^3}\right]$$

$$= 5{\cdot}026 \times 10^{-7}\,(1000 - 125) = \mathbf{4{\cdot}4 \times 10^{-3}\ N}$$

CHAPTER
4

Earth's magnetism

4.01. EARTH'S MAGNETISM

Whenever a bar magnet is suspended freely (near the equator), its N-pole points wards the geographical north and S-pole towards the geographical south of the rth. William Gilbert suggested that earth itself behaves as a huge magnet. It was ssumed that a huge magnet is lying deep inside the earth with its S-pole towards e geographical north and N- pole towards the south of the earth. It, then, easily xplains as to why the N-pole of a freely suspended bar magnet always points wards the geographical north of the earth. It may be pointed out that the line ining the geographic north and south of the earth, called geographic axis (or eographical N-S line) makes a small angle (≈ 20°)with the magnetic axis (or agnetic N-S line). Fig. 4.01 represents the magnetic field lines around the earth.

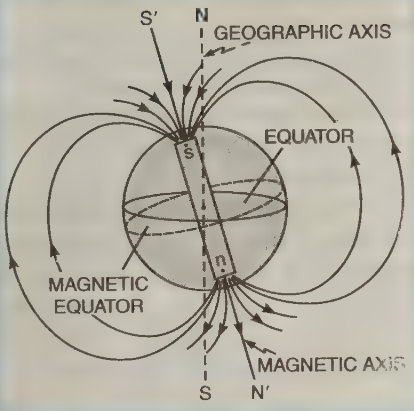

Fig. 4.01

The axis of rotation of earth is called ***geographic axis*** and the points, where it uts the surface of earth are called ***geographic poles***. The points N and S represent e geographic north and south poles. The great circle on the earth's surface erpendicular to the geographic axis is called ***equator***.

*A vertical plane passing through the geographic axis is called the **geographic meridian**.*

The axis of the huge magnet assumed to be lying inside the earth is called ***agnetic axis*** of the earth and the points, where the magnetic axis cuts the earth's urface are called ***earth's magnetic poles***. The points N′ and S′ indicate the magnetic orth and south of the earth. The great circle on the earth's surface perpendicular the magnetic axis is called ***magnetic equator***.

*A vertical plane passing through the magnetic axis of the earth is called **magnetic eridian**.*

The geographic and magnetic axis of the earth do not coincide with each other. he magnetic axis of earth makes an angle of about 20° with the geographic axis. It ollows that when a magnet is freely suspended, its north pole will point towards agnetic south (S′) and south pole towards magnetic north (N′). In other words, he poles of a freely suspended magnet only approximately point towards eographic north and south. The magnetic north and south poles are in fact at a quite arge distance from the geographic poles. At present, the magnetic south pole is ocated in Northern Canada and is about 1600 km from the geographic north at 73° orth lattitude and 96° west longitude. The north magnetic pole is at the iametrically opposite point *i.e.* at 75° south lattitude and 84° east longitude.

Cause of earth's magnetism. It may be pointed out that the source of earth's agnetism is not a large solid mass of magnetic material located inside the earth. t is guessed that earth's magnetism is due to molten charged metallic fluid. It ives rise to a current flowing inside the core of the earth. This core has a radius of bout 3500 km. Upto a distance of about 3×10^4 km (≈ five earth's radii), the agnetic field is entirely due to earth's magnetism. At larger distances, the motion f the ions influence the earth's magnetic field. The motion of the ions is affected by thin hot gas expelled by the sun, called ***solar wind***.

Prof. Blackett studied earth's magnetism in detail and suggested that since very substance is made up of charged particles (protons and electrons), hence a ubstance rotating about an axis will become magnetised. The earth's magnetism s also due to the rotation of the earth about its own axis.

There is another theory about the earth's magnetism. The gases in the tmosphere are in the ionised states. The high energy radiation coming from the un ionises the atoms in the upper part of the atmosphere. The radioactivity of the tmosphere and cosmic rays also ionise the gases in the atmosphere. Hence, due o rotation of the earth, strong electric currents flow. Due to action of these currents, he earth is magnetised.

Key point

The earth's magnetism cannot be due to the magnetisation of iron deposits inside the earth. It is because iron (if magnetised) can not retain magnetism at the high temperature inside the earth.

The third view regarding earth's magnetism is that the core of the earth is made of iron and **nickel**. Due to rotation, the earth behaves as a dynamo and becomes magnetised.

4.02. MAGNETIC ELEMENTS

The physical quantities, which determine the intensity of earth's total magnetic field completely (both in magnitude and direction), are called ***magnetic elements.***

Following are three magnetic elements of earth :

1. Magnetic declination. *Declination at a place is the angle between the geographic meridian and the magnetic meridian.* It is denoted by θ.

If ABCD and AB′C′D represent magnetic and geographical meridian, then $\angle$ BAB' = θ represents the magnetic declination [Fig. 4.02].

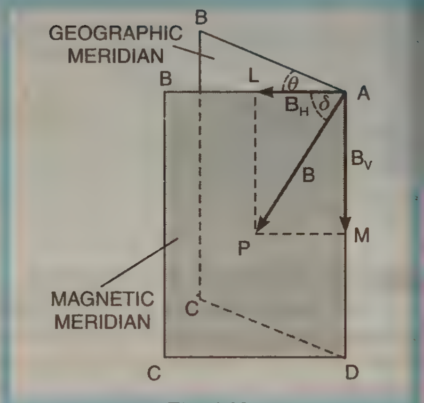

Fig. 4.02

2. Magnetic inclination or dip. *Dip at a place is defined as the angle made by the direction of the earth's total magnetic field with the horizontal direction.* It is denoted by δ.

Suppose that a small bar magnet is suspended freely at point A and it points in direction AP. Then, AP is the direction of the intensity of earth's total magnetic field (B). The line AP lies in magnetic meridian.

Consider that AB is a horizontal line in the magnetic meridian. Then, $\angle$ BAP = δ represents the dip at point A.

3. Horizontal component of earth's magnetic field. *It is the component of earth's magnetic field along the horizontal direction.*

It is denoted by B_H.

Drop PL perpendicular to AB and PM perpendicular to AD.

Then, AL and AM represent horizontal component (B_H) and vertical component (B_V) of earth's total magnetic field. In right angled triangle ALP,

$$\cos\delta = \frac{AL}{AP} = \frac{B_H}{B}$$

or

$$B_H = B\cos\delta \qquad ...(4.01)$$

Key point

The direction of horizontal component of earth's magnetic field is from geographic south to geographic north above the surface of earth.

Also,

$$\sin\delta = \frac{LP}{AP} = \frac{AM}{AP} = \frac{B_V}{B}$$

or

$$B_V = B\sin\delta \qquad ...(4.02)$$

Squaring and adding the equations (4.01) and (4.02), we have

$$B_H{}^2 + B_V{}^2 = B^2\cos^2\delta + B^2\sin^2\delta = B^2$$

or

$$B = \sqrt{B_H{}^2 + B_V{}^2} \qquad ...(4.03)$$

Dividing equation (4.02) by (4.01), we have

$$\frac{B\sin\delta}{B\cos\delta} = \frac{B_V}{B_H}$$

or

$$\tan\delta = \frac{B_V}{B_H} \qquad ...(4.04)$$

Watch out !

A magnet suspended freely at equator will orient itself parallel to the surface of earth, while one suspended at pole will stand vertically !

4.03. NEUTRAL POINT ANDTO FIND MAGNETIC MOMENT OF A BAR MAGNET

Neutral point. *A neutral point in the magnetic field of a bar magnet is that point, where the field due to the magnet is completely neutralised by the horizontal component of earth's magnetic field.*

Thus, at the neutral point, the magnetic field due to the bar magnet (B) is just equal and opposite to the horizontal component of earth's magnetic field (B_H) *i.e.*

$$B = B_H \qquad ...(4.05)$$

To find magnetic moment of a bar magnet. The magnetic moment of a bar magnet can be found by plotting magnetic field of the magnet, locating the neutral points and then using the equation (4.05).

(a) When magnet is placed with its north pole towards north of the earth. If we plot the magnetic field due to a small bar magnet by placing its north pole towards north of the earth, then plot of the magnetic field of the magnet (which is superposed by earth's magnetic field) will be as shown in Fig. 4.03.

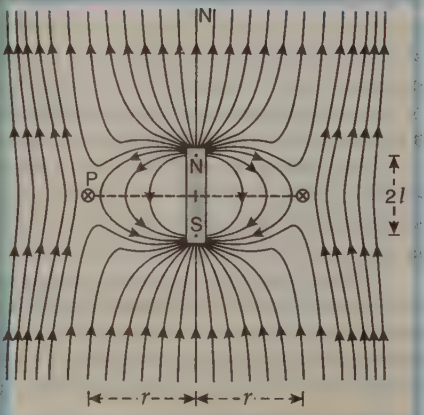

Fig. 4.03

The horizontal component of earth's magnetic field and the magnetic field due to the bar magnet cancel out at the two cross-marks on the equitorial line of the magnet (the normal bisector of the magnet) and these points are called *neutral points.* Let *r* be distance of a neutral point from the centre of the magnet. As the neutral nt lies on the equitorial line of the magnet, the magnetic field due to the magnet ne neutral point is given by

$$B_{equi} = \frac{\mu_0}{4\pi} \cdot \frac{M}{(r^2 + l^2)^{3/2}},$$

where M is magnetic dipole moment of the magnet.

Since at the neutral point, magnetic field due to the magnet is equal to B_H, we e

$$\frac{\mu_0}{4\pi} \cdot \frac{M}{(r^2 + l^2)^{3/2}} = B_H \qquad ...(4.06)$$

In case, if the magnet is so small that l^2 can be neglected as compared to r^2, then

$$\frac{\mu_0}{4\pi} \cdot \frac{M}{r^3} = B_H \qquad ....(4.07)$$

Knowing r and B_H, the magnetic dipole moment of the bar magnet can be ulated from the equations (4.06) and (4.07).

Key point

When a magnet is placed with its S-pole towards north of the earth, neutral points are obtained on its axial line. On the other hand, when magnet is placed with its N-pole towards north of the earth, neutral points lie on its equitorial line. Thus, neutral points are displaced through 90° on rotating the magnet through 180°. In general, when a magnet is rotated through an angle θ, neutral points turn through an angle $\theta/2$.

(b) When magnet is placed with its south pole towards north of the earth. The of the magnetic field of a bar magnet in this case will be as shown in Fig. 4.04.

In this case, the neutral points are found to be on axial line of the magnet. If tral point is at a distance r from the centre of the magnet, then magnetic field to the magnet at the neutral point (point on the axial line of the magnet) is given

$$B_{axial} = \frac{\mu_0}{4\pi} \cdot \frac{2Mr}{(r^2 - l^2)^2}$$

Since at the neutral point, the magnetic field due to the magnet is equal to B_H, have

$$\frac{\mu_0}{4\pi} \cdot \frac{2Mr}{(r^2 - l^2)^2} = B_H \qquad ...(4.08)$$

In case, if the magnet is so small that l^2 can be neglected as compared to r^2, then

$$\frac{\mu_0}{4\pi} \cdot \frac{2M}{r^3} = B_H \qquad ...(4.09)$$

Knowing r and B_H, the equations (4.08) and (4.09) can be used to find the gnetic dipole moment of the bar magnet.

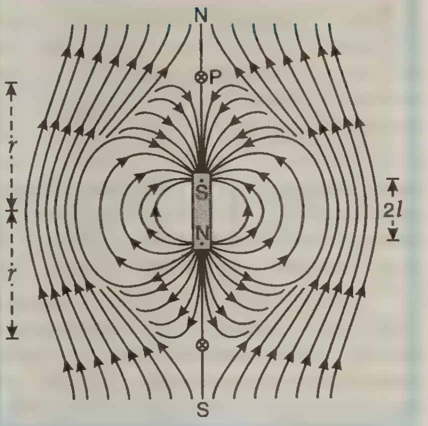

Fig. 4.04

Note. From the plot of magnetic field in the two cases *i.e.* when magnet is placed h its N-pole towards north of earth and when magnet is placed with its S-pole ards north of the earth, it follows that when magnet is turned through 180°, the tral points turn through 90°.

4.04. TANGENT LAW

Tangent law. *If a small bar magnet is suspended in two mutually perpendicular form magnetic fields $\vec{B}$ and $\vec{B}_H$, such that it comes to rest making an angle θ with the ction of field $\vec{B}_H$, then*

$$B = B_H \tan\theta \qquad ...(4.10)$$

Proof. Consider that a small bar magnet NS is placed in two uniform magnetic ds B and B_H acting at right angles to each other. Let m be the pole strength of h pole and $2\,l$ be the length of the magnet. The force on the north pole of the gnet due to the magnetic field will act along the direction of the field, while the ce on south-pole will be along a direction opposite to the direction of the field . 4.05]. Each magnetic field produces a torque on the magnet. The torque due he magnetic field B_H tends to rotate the magnet in anticlockwise direction, while t due to magnetic field B in clockwise direction. Suppose that the magnet comes he equilibrium position, where it makes an angle θ with the direction of magnetic d B_H.

Torque due to the magnetic field B_H,

$$\tau_1 = m\,B_H \times KN$$

Torque due to the magnetic field B,

$$\tau_2 = m\,B \times KS$$

In equilibrium, $\tau_1 = \tau_2$

i.e. $m\,B \times KS = m\,B_H \times KN$

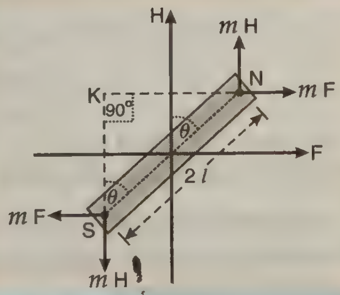

Fig. 4.05

or $$B = B_H \times \frac{KN}{KS}$$

But from the right angled triangle S K N,

$$\frac{KN}{KS} = \tan\theta$$

From the above two equations, we have

$$B = B_H \tan\theta$$

It proves the tangent law. The above result holds only, when the two magnetic fields are uniform over the entire length of the magnet.

4.05. TANGENT GALVANOMETER

A tangent galvanometer is an instrument used to measure very small currents. Further, it is a galvanometer of ***moving magnet and fixed coil type.***

Principle. It is based on tangent law in magnetism.

Construction. It consists of a non-magnetic circular frame mounted on a horizontal turn table provided with levelling screws [Fig. 4.06]. Three coils having 2 ; 50 and 500 turns are wound on the circular frame and their ends are connected to binary terminals provided over the base of the instrument. The coil can be rotated about a vertical axis passing through the centre of the instrument. A circular compass box made of non-magnetic material is mounted at the centre of the coil. The compass box has a small magnetic needle *n s* pivoted at its centre, which is free to move over the horizontal circular scale of the compass box. The circular scale is divided into four quadrants of 0° – 90° each. To note the position of the magnetic needle accurately, a long aluminium pointer is attached at right angle to the magnetic needle. Also, a plane mirror is fixed below the pointer to remove error due to parallax, while reading the position of the pointer. The reading of the pointer is taken in the position, where the image of the pointer coincides with the pointer itself.

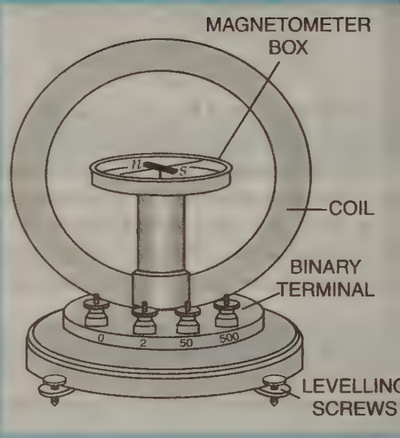

Fig. 4.06

Setting. The tangent galvanometer is levelled with the help of levelling screws and the coil is rotated, till its plane becomes parallel to the length of the magnetic needle. In this position, the plane of the coil lies along the magnetic meridian *i.e.* the horizontal component of earth's magnetic field is in the plane of the coil. Now, the compass box is rotated, so that the pointer comes along 0°- 0° line.

Theory. When current is passed through the coil, the magnetic field (B) is produced at the centre of the coil in a direction perpendicular to the plane of the coil. Since, galvanometer has been set in a position such that the horizontal component of earth's magnetic field (B_H) is in the plane of the coil ; the magnetic needle will be under the action of two mutually perpendicular magnetic fields. If θ is deflection of the needle, then according to tangent law,

$$B = B_H \tan\theta \qquad \text{...(4.11)}$$

If the coil has *n* turns and radius *a*, then magnetic field produced at the centre of the coil on passing current I is given by

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} \qquad \text{...(4.12)}$$

From equations (4.11) and (4.12), we have

$$\frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} = B_H \tan\theta$$

or $$I = \frac{2a}{n\mu_0} B_H \tan\theta \qquad \text{...(4.13)}$$

Knowing *a*, *n*, θ and B_H ($0{\cdot}32 \times 10^{-4}$ tesla approximately), the value of current I through the coil can be calculated.

In the above equation, the factor $\frac{n\mu_0}{2a}$ is a constant for the given galvanometer and likewise it is called ***galvanometer constant***. It is denoted by G. Therefore, equation (4.13) reduces to

$$I = \frac{B_H}{G} \tan\theta \qquad \text{...(4.14)}$$

Further, the factor $\frac{B_H}{G}$ is called ***reduction factor*** of the tangent galvanometer and is denoted by K. Therefore, equation (4.14) becomes

$$I = K \tan\theta \qquad \text{...(4.15)}$$

Key point

Reduction factor of a tangent galvano
meter depends upon the geometry of it
coil. It increases with increase of radiu
and decrease in number of turns of the coi
of the galvanometer.

If $\theta = 45°$, then $I = K \tan 45°$ or $K = I$

Thus, *reduction factor of a tangent galvanometer is numerically equal to the current* *mpere) through the galvanometer, which produces a deflection of 45°, when the plane* *s coil lies in the magnetic meridian.*

4.06. VIBRATION MAGNETOMETER

It is an instrument used to compare magnetic moments of two bar magnets or etermine the horizontal component of earth's magnetic field.

Principle. *It is based on the principle that when a bar magnet suspended freely in a* *orm magnetic field is displaced from its equilibrium position, it starts executing simple* *nonic motion about the equilibrium position.*

Construction. A vibration magnetometer consists of a wooden box with its es made of glass. A long brass or glass tube is fixed vertically at the top of the . At the upper end of tube, a screw is provided to suspend *an unspun silken thread* *air of a horse.* The lower end of the silken thread carries an arrangement, called rup (a hook of peculiar shape and made of non-magnetic substance), in which magnet can be placed. A plane mirror is fitted over the base of the instrument, he centre of which a line is drawn in a direction parallel to its length [Fig. 4.07]. s line is called the *index line.*

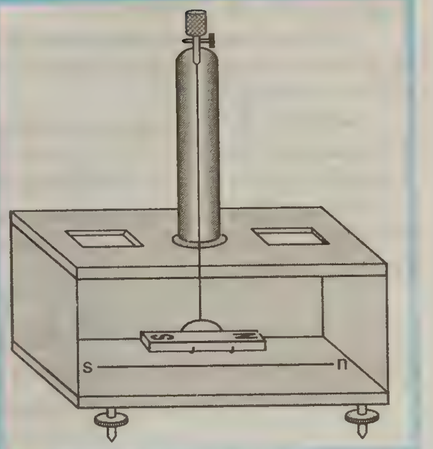

Fig. 4.07

The magnet placed in the stirrup suspends horizontally above the index line. en the magnet vibrates, its vibrations can be counted by observing its vibratory tion through the glass walls.

Setting. To set the vibration magnetometer, place the magnetic compass needle the index line. The magnetometer is rotated, till the compass needle becomes allel to the index line. The line now represents the magnetic N-S line. In order make the suspension fibre torsionless, a brass bar nearly of the size of the magnet laced in the stirrup. The screw is then adjusted to bring the brass bar in the gnetic meridian. The brass bar is then replaced by the magnet, with its north pole inting towards north of the earth.

Theory. Consider that a magnet having the magnetic dipole moment M is ely suspended in earth's magnetic field B_H. In equilibrium position, it will point the N-S direction. If the magnet is displaced through an angle θ, a torque equal $M B_H \sin\theta$ acts on it, which tends to bring it back to its equilibrium position. As magnet reaches the mean position, it acquires kinetic energy and overshoots the uilibrium position and thus executes oscillations.

If I is moment of inertia of the magnet about the suspension axis and α, the gular acceleration produced, then

$$I\alpha = -M B_H \sin\theta$$

If θ is small, then $\sin\theta \approx \theta$ and hence the angular acceleration (in magnitude) given by

$$\alpha = \frac{M B_H}{I}\theta \qquad \text{...(4.16)}$$

For a given magnet, the factor $\frac{M B_H}{I}$ is a constant and therefore, angular celeration (α) is directly proportional to angular displacement (θ). Hence, the riodic motion of the vibrating magnet is S.H.M. Therefore, time period of vibration the magnet is given by

$$T = 2\pi\sqrt{\frac{\text{angular displacement}}{\text{angular acceleration}}} = 2\pi\sqrt{\frac{\theta}{\alpha}}$$

Using equation (4.16), we have

$$T = 2\pi\sqrt{\frac{I}{M B_H}} \qquad \text{...(4.17)}$$

For a rectangular bar magnet, the moment of inertia of the magnet about the is of oscillation through its C.G. is given by

$$I = \text{mass} \times \frac{a^2 + b^2}{12},$$

here a and b are the geometrical length and breadth of the bar magnet.

The relation (4.17) may be used to find the magnetic dipole moment of a bar magnet by noting the period of vibration. In case B_H is not known, the relation can be used to compare magnetic dipole moments of two bar magnets.

4.57. USES OF A VIBRATION MAGNETOMETER

A vibration magnetometer can be used to compare the magnetic moments of two bar magnets, to compare horizontal components of earth's magnetic field at two different places ; and together with a deflection magnetometer, it can be used to find the magnetic moment of a magnet and the horizontal component of earth's magnetic field at a given place.

1. To compare magnetic moments of two bar magnets. Let us study the use of vibration magnetometer, when the two given bar magnets are of (*a*) equal sizes and (*b*) of unequal sizes.

(a) When the bar magnets are of equal sizes. Consider two bar magnets A and B of same size and mass. Let M_1 and M_2 be the magnetic moments of the magnets A and B respectively and I be the moment of inertia of each magnet.

Set the vibration magnetometer, so that the suspension fibre is torsionless and the stirrup rests along N-S line. Place the magnet A in the stirrup and find its time period T_1. Then,

$$T_1 = 2\pi\sqrt{\frac{I}{M_1 B_H}}, \qquad \text{...(4.18)}$$

where B_H is horizontal component of the earth's magnetic field.

By proceeding in the same manner, find the time period T_2 of magnet B. Then,

$$T_2 = 2\pi\sqrt{\frac{I}{M_2 B_H}} \qquad \text{...(4.19)}$$

Dividing equation (4.19) by (4.18), we have

$$\frac{T_2}{T_1} = \sqrt{\frac{I}{M_2 B_H}} \times \sqrt{\frac{M_1 B_H}{I}} = \sqrt{\frac{M_1}{M_2}}$$

or $$\frac{M_1}{M_2} = \frac{T_2^2}{T_1^2} \qquad \text{...(4.20)}$$

Knowing T_1 and T_2, the ratio M_1/M_2 can be found.

(b) When the bar magnets are of unequal sizes. Consider two unequal magnets A and B having moment of inertia I_1 and I_2 and magnetic moments M_1 and M_2 respectively.

Set the vibration magnetometer, so that the suspension fibre is torsionless and the stirrup rests along the N-S line. By placing the two magnets A and B together in the stirrup, so that their like poles are in the same direction [Fig. 4.08], the time period T_1 of the combination is found. Then,

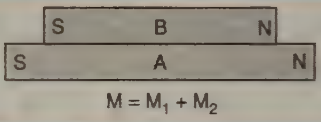

Fig. 4.08

$$T_1 = 2\pi\sqrt{\frac{I}{M B_H}},$$

where I and M are the vlaues of moment of inertia and magnetic moment of the combination of the two magnets. Since the like poles of the two magnets are in same direction,

$$M = M_1 + M_2$$

$$\therefore \qquad T_1 = 2\pi\sqrt{\frac{I}{(M_1 + M_2) B_H}} \qquad \text{...(4.21)}$$

Now, the two magnets are placed in the stirrup, so that their opposite poles are in same direction [Fig. 4.09]. If T_2 is time period of the combination in this case, then

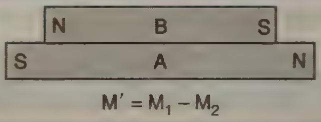

Fig. 4.09

$$T_2 = 2\pi\sqrt{\frac{I}{M' B_H}}$$

Here, M′ is magnetic moment of the combination of the two magnets in this case. Since, the like poles of the two magnets are in opposite direction,

$$M' = M_1 - M_2$$

$$\therefore \qquad T_2 = 2\pi\sqrt{\frac{I}{(M_1 - M_2)\,B_H}} \qquad \text{...(4.22)}$$

Dividing equation (4.21) by (4.22), we have

$$\frac{T_2}{T_1} = \sqrt{\frac{I}{(M_1 - M_2)\,B_H}} \times \sqrt{\frac{(M_1 + M_2)\,B_H}{I}} = \sqrt{\frac{M_1 + M_2}{M_1 - M_2}}$$

$$\text{or} \qquad \frac{M_1 + M_2}{M_1 - M_2} = \frac{T_2^2}{T_1^2}$$

Applying componendo and dividendo, we have

$$\text{or} \qquad \frac{(M_1 + M_2) + (M_1 - M_2)}{(M_1 + M_2) - (M_1 - M_2)} = \frac{T_2^2 + T_1^2}{T_2^2 - T_1^2}$$

$$\text{or} \qquad \frac{M_1}{M_2} = \frac{T_2^2 + T_1^2}{T_2^2 - T_1^2} \qquad \text{...(4.23)}$$

Knowing T_1 and T_2, the ratio M_1/M_2 can be found.

2. To compare horizontal components of earth's magnetic field at two places. Consider a magnet having moment of inertia I and magnetic moment M. Let B_H and B_H' be the values of horizontal components of earth's magnetic field at two places A and B respectively.

If T and T′ are the values of time period of the magnet at the place A and B respectively, then

$$T = 2\pi\sqrt{\frac{I}{M\,B_H}} \qquad \text{...(4.24)}$$

$$\text{and} \qquad T' = 2\pi\sqrt{\frac{I}{M\,B_H'}} \qquad \text{...(4.25)}$$

Dividing equation (4.25) by (4.24), we have

$$\frac{T'}{T} = \sqrt{\frac{I}{M\,B_H'}} \times \sqrt{\frac{M\,B_H}{I}} = \sqrt{\frac{B_H}{B_H'}}$$

$$\text{or} \qquad \frac{B_H}{B_H'} = \frac{T'^2}{T^2} \qquad \text{...(4.26)}$$

Knowing T and T′, the ratio B_H/B_H' can be found.

SOLVED NUMERICAL PROBLEMS

Type A. On Magnetic elements

Problem 4.01. The declination at a place is 12°west of north. Find in what direction, a ship should stear so that it reaches a place due east ?

Sol. The dotted N-S line represents geographical N S-line and the compass needle *n s* points 12° west of geographical north [Fig. 4.10]. Therefore, the ship would reach a place due east, if it stears 12° + 90° *i.e.* **102°** ***with the direction of the compass needle.***

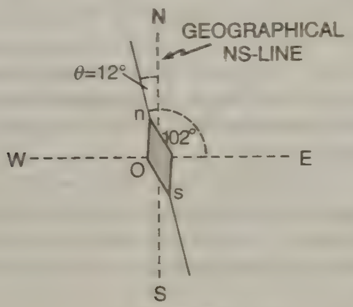

Fig. 4.10

Problem 4.02. A ship is sailing due east according to Mariner's compass. If the declination of that place is 18° east of north, what is the true direction of the ship ?

Sol. The compass needle *n s* points along magnetic N S-line and the ship is sailing along OP *i.e.* towards east (as indicated by compass needle). As the declination of that place is 18° east of north, the geographical N-S line is as shown by dotted N-S line [Fig. 4.11]. Thus, true direction of ship is 18° ***south of east.***

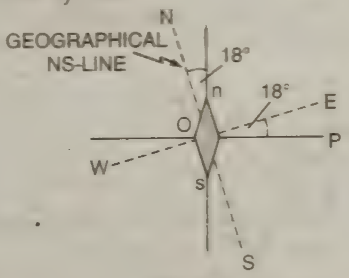

Fig. 4.11

Problem 4.03. At a certain location in Africa, a compass points 12° west of the geographic north. The north tip of the

magnetic needle of a dip circle placed in the plane of magnetic meridian points 60° above the horizontal. The horizontal component of the earth's field is measured to be 0·16 G. Specify the direction and magnitude of the earth's field at the location. *(Text Problem)*

Sol. Here, angle of dip, $\delta = 60°$

horizontal component of earth field, $B_H = 0{\cdot}16$ G

Let earth's magnetic field be equal to B.

Then $\qquad B_H = B \cos \delta$

$$\text{or} \qquad B = \frac{B_H}{\cos \delta} = \frac{0 \cdot 16}{\cos 60°} = \frac{0 \cdot 16}{0 \cdot 5} = 0 \cdot 32 \text{ G}$$

Thus, earth's magnetic field has a magnitude of 0·32 G and lies in a vertical plane 12° *west of geographic meridian making an angle of* 60° *(upwards) with the horizontal.*

Problem 4.04. The true value of dip at a place is 45°. If the plane of the dip circle is turned through 60° from the magnetic meridian, what will be the apparent value of the dip ?

Sol. On turning the dip circle through 60°, the apparent value of the horizontal component of earth's magnetic field becomes

$$BH' = B_H \cos 60°$$

However, vertical component of earth's field remains unchanged. If δ' is apparent value of dip, then

$$\tan \delta' = \frac{B_V'}{B_H'} = \frac{B_V}{B_H \cos 60°} \qquad (\because B_V' = B_V)$$

$$\text{Now} \qquad \frac{B_V}{B_H} = \tan \delta,$$

where δ is true dip at that place.

$$\text{Therefore, } \tan \delta' = \frac{\tan \delta}{\cos 60°} = \frac{1}{0 \cdot 5} = 2 \cdot 0$$

$$\text{or} \qquad \delta' = 63{\cdot}4°$$

Problem 4.05. If δ_1 and δ_2 be the angles of dip observed in two planes at right angles to each other and δ is the true angle of dip, prove that *(P.S.S.C.E. 1996)*

$$\cot^2 \delta_1 + \cot^2 \delta_2 = \cot^2 \delta$$

Sol. Let B_H and B_V be the horizontal and vertical components of the earth's magnetic field. As δ is true angle of dip,

$$\tan \delta = \frac{B_V}{B_H} \qquad \text{...}(i)$$

Planes 1 and 2 are at right angles to each other. If plane 1 makes an angle θ with the magnetic meridian, then plane 2 will make angle $(90° - \theta)$ with the magnetic meridian as shown in Fig. 4.12.

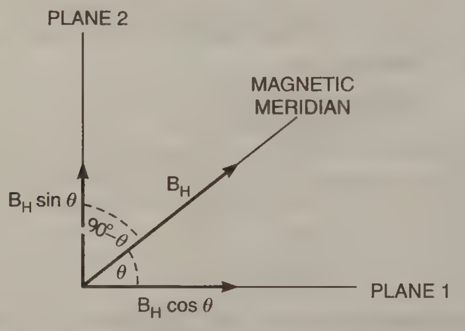

Fig. 4.12

Whereas the vertical component of earth's magnetic field remains unaffected in the two planes, the effective horizontal components of earth's magnetic field in plane 1 and 2 a $B_H \cos \theta$ and $B_H \sin \theta$ respectively. Therefore, angle of d δ_1 in plane 1 is given by

$$\tan \delta_1 = \frac{B_V}{B_H \cos \theta} \qquad \text{or} \qquad \cos \theta = \frac{B_V}{B_H \tan}$$

Using equation (*i*), we have

$$\cos \theta = \frac{\tan \delta}{\tan \delta_1} \qquad \text{...(}$$

Further, angle of dip δ_2 in plane 2 is given by

$$\tan \delta_2 = \frac{B_V}{B_H \sin \theta}$$

Again using equation (*i*), we obtain

$$\sin \theta = \frac{\tan \delta}{\tan \delta_2} \qquad \text{...(}$$

Squaring and adding equations (*ii*) and (*iii*), we hav

$$\frac{\tan^2 \delta}{\tan^2 \delta_1} + \frac{\tan^2 \delta}{\tan^2 \delta_2} = \cos^2 \theta + \sin^2 \theta = 1$$

$$\text{or} \qquad \frac{1}{\tan^2 \delta_1} + \frac{1}{\tan^2 \delta_2} = \frac{1}{\tan^2 \delta}$$

$$\text{or} \qquad \cot^2 \delta_1 + \cot^2 \delta_2 = \cot^2 \delta$$

Type B. On Neutral points

Problem 4.06. A bar magnet 30 cm long is placed in t magnetic meridian with its north pole pointing south. T neutral point is observed at a distance of 30 cm from its o end. Calculate the pole strength of the magnet. Give horizontal component of earth's field = 0·34 G.

Sol. Here, $2\,l = 30$ cm or $l = 15$ cm $= 0{\cdot}15$ m ;

$r = 30$ cm $= 0{\cdot}30$ m,

$B_H = 0{\cdot}34 \text{ G} = 0{\cdot}34 \times 10^{-4}$ T

When magnet is placed with its north pole pointi south, neutral point is obtained on its axial line. Therefo at the neutral point,

$$B_{axial} = B_H$$

$$\text{or} \qquad \frac{\mu_0}{4\pi} \times \frac{2\,M\,r}{(r^2 - l^2)^2} = B_H$$

$$\text{or} \qquad M = \frac{4\pi}{\mu_0} \times \frac{B_H (r^2 - l^2)^2}{2r}$$

$$= \frac{1}{10^{-7}} \times \frac{0 \cdot 34 \times 10^{-4} \times (0 \cdot 30^2 - 0 \cdot 15^2)^2}{2 \times 0 \cdot 30}$$

$$= \frac{0 \cdot 34 \times 10^{-4} \times (0 \cdot 0675)^2}{10^{-7} \times 2 \times 0 \cdot 30} = 2 \cdot 582 \text{ A m}^2$$

The pole strength of the magnet,

$$m = \frac{M}{2\,l} = \frac{2 \cdot 582}{0 \cdot 30} = 8 \cdot 606 \text{ A m}$$

Problem 4.07. A bar magnet is 10 cm long. Its magne moment is 0·4 A m^2. It is placed in magnetic meridian wi its north pole towards north. If the neutral point is obtain at a distance of 10 cm from the centre of the magnet, fi the horizontal component of earth's magnetic field.

Sol. Here, $M = 0{\cdot}4 \text{ A m}^2$; $r = 10$ cm $= 0{\cdot}1$ m ;

$2\,l = 10$ cm or $l = 5$ cm $= 0{\cdot}05$ m

When magnet is placed with its north pole towards no of earth, the neutral point is obtained on the equitorial li If B_H is horizontal component of earth's field, then at t neutral point

$$B_{equi} = B_H$$

$$\text{or } B_H = \frac{\mu_0}{4\pi} \times \frac{M}{(r^2 + l^2)^{3/2}}$$

$$= \frac{10^{-7} \times 0 \cdot 4}{(0 \cdot 1^2 + 0 \cdot 05^2)^{3/2}} = \frac{10^{-7} \times 0 \cdot 4}{(0 \cdot 0125)^{3/2}} = \frac{10^{-7} \times 0 \cdot 4}{0 \cdot 0014}$$

$$= \mathbf{0 \cdot 286 \times 10^{-4}\ T}$$

Problem 4.08. A long straight horizontal cable carries current of 2·5 A in the direction 10° north of east. The agnetic meridian of the place happens to be 10° west of e geographic meridian. The earth's magnetic field at the cation is 0·33 G and the angle of dip is zero. Locate the ne of neutral point. (Ignore the thickness of the ble). *(Text Problem)*

Sol. The magnetic $n - s$ line is 10° west of geographical –S line as shown in Fig. 4.13. The straight horizontal cable Y is 10° north of east.

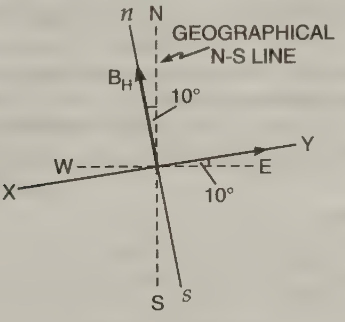

Fig. 4.13

Here, $\delta = 0°$ and $B = 0 \cdot 33$ G

The horizontal component of earth's field,

$$B_H = \frac{B}{\cos \delta} = \frac{0 \cdot 33}{\cos 0°} = 0 \cdot 33\ G = 0 \cdot 33 \times 10^{-4}\ T$$

At a point below the cable, the direction of the magnetic eld produced is same as that of B_H, while at a point above ne cable, the direction of the field produced is opposite to that f B_H. Therefore, neutral point will lie above the cable. If the istance of the neutral point from the wire is a, then,

$$\frac{\mu_0}{4\pi} \cdot \frac{2I}{a} = B_H \qquad \text{or} \qquad a = \frac{\mu_0}{4\pi} \times \frac{2I}{B_H}$$

Here $\quad I = 2 \cdot 5$ A

$$\therefore \quad a = 10^{-7} \times \frac{2 \times 2 \cdot 5}{0 \cdot 33 \times 10^{-4}} = 1 \cdot 5 \times 10^{-2}\ m = \mathbf{1 \cdot 5\ cm}$$

ype C. On Tangent law and Tangent Galvanometer

Problem 4.09. A current carrying planar loop suspen-ed in a vertical plane normal to the magnetic meridian is n stable equilibrium. The horizontal component of earth's agnetic field is 0·32 G. Another horizontal magnetic field of magnitude 0·48 G parallel to the plane of the loop is set up along magnetic west to east. Specify the new stable equilibrium. *(Text Problem)*

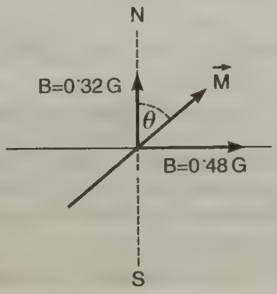

Fig. 4.14

Sol. Suppose that the current loop behaves as a magnetic dipole of magnetic moment $\vec{M}$. It will come to equilibrium in a position making angle θ with B_H [Fig. 4.14], such that

$$\frac{B}{B_H} = \tan \theta \qquad \text{(tangent law)}$$

Here, $\quad B_H = 0 \cdot 32$ G ; $B = 0 \cdot 48$ G

$$\therefore \quad \tan \theta = \frac{0 \cdot 48}{0 \cdot 32} = 1 \cdot 5$$

$$\text{or} \quad \theta = \mathbf{56 \cdot 3°} \quad \textbf{(east of north)}$$

Problem 4.10. A tangent galvanometer has a coil of 22 turns and mean radius 0·1 m. Find the reduction factor at a place, where $B_H = 0 \cdot 3 \times 10^{-4}$ T. *(Karnataka, 1986 S)*

Sol. Here, $\quad n = 22$; $a = 0 \cdot 1$ m ; $B_H = 0 \cdot 3 \times 10^{-4}$ T

We know that $\mu_0 = 4\pi \times 10^{-7}$ T m A^{-1}

Reduction factor,

$$K = \frac{2a}{n\mu_0} B_H = \frac{2 \times 0 \cdot 1}{22 \times 4\pi \times 10^{-7}} \times 0 \cdot 3 \times 10^{-4}$$

$$= \mathbf{0 \cdot 217\ A}$$

Problem 4.11. A tangent galvanometer has a coil of 40 turns and of radius 12 cm. A steady current of 0·15 A, when passed through the coil, produces a deflection of 45° in the galvanometer. Calculate the strength of the horizontal component of the earth's magnetic field at the centre of the coil of the galvanometer. *(H.S.S.C.E. 1998)*

Sol. Here, $n = 40$; $a = 12$ cm $= 0 \cdot 12$ m ; $I = 0 \cdot 15$ A ; $\theta = 45°$

Also, $\quad \mu_0 = 4\pi \times 10^{-7}$ T m A^{-1}

$$\text{Now,} \quad I = \frac{2a}{n\mu_0} B_H \tan \theta$$

$$\text{or} \quad B_H = \frac{n\mu_0}{2a} \cdot \frac{I}{\tan \theta}$$

$$= \frac{40 \times 4\pi \times 10^{-7}}{2 \times 0 \cdot 12} \times \frac{0 \cdot 15}{\tan 45°} = \mathbf{0 \cdot 314 \times 10^{-4}\ T}$$

Problem 4.12. Two tangent galvanometers having equal radius of coils are connected in parallel to an electric cell. The ratio of the currents in the galvanometers are 1 : 2 and respective mean deflections are 30° and 45°. Compare the ratio of the number of turns of the tangent galvano-meters. *(C.B.S.E. 2002)*

Sol. The current passing through a tangent galvano-meter is given by

$$I = \frac{2a}{n\mu_0} B_H \tan \theta$$

Let n_1 and n_2 be number of turns of the two tangent galvanometers. Since the two galvanometers have coils of equal radii,

$$\frac{I_1}{I_2} = \frac{n_2}{n_1} \cdot \frac{\tan \theta_1}{\tan \theta_2} \qquad \text{or} \qquad \frac{n_1}{n_2} = \frac{I_2}{I_1} \cdot \frac{\tan \theta_1}{\tan \theta_2}$$

$$\text{or} \quad \frac{n_1}{n_2} = \frac{1}{I_1 / I_2} \cdot \frac{\tan \theta_1}{\tan \theta_2}$$

$$\text{Here,} \quad \frac{I_1}{I_2} = \frac{1}{2} ; \theta_1 = 30° \qquad \text{and} \qquad \theta_2 = 45°$$

$$\therefore \quad \frac{n_1}{n_2} = \frac{1}{1/2} \cdot \frac{\tan 30°}{\tan 45°} = \frac{2 \times 0 \cdot 5774}{1} = \mathbf{1 \cdot 155}$$

Type D. On Vibration Magnetometer

Problem 4.13. A circular coil of 16 turns and radius 10 cm carrying a current of 0·75 A rests with its plane normal to an external field of magnitude $5{\cdot}0 \times 10^{-2}$ T. The coil is free to turn about an axis in its plane perpendicular to the field direction. When the coil is turned slightly and released, it oscillates about its stable equilibrium with a frequency of $2{\cdot}0\ \text{s}^{-1}$. What is the moment of inertia of the coil about its axis of rotation ?

Sol. Here, $n = 16$; $a = 10$ cm = 0·1 m ;

current* through the coil, $i = 0{\cdot}75$ A

The magnetic dipole moment of the coil,

$$M = n\,i\,A = n\,i \times \pi a^2$$
$$= 16 \times 0{\cdot}75 \times \pi \times (0{\cdot}1)^2 = 0{\cdot}377\ \text{A m}^2$$

The time period of oscillation is given by

$$T = 2\pi\sqrt{\frac{I}{M B_H}}$$

$$\therefore \quad I = \frac{T^2 M B_H}{4\pi^2} = \frac{M B_H}{4\pi^2 \nu^2},$$

where $\nu = \frac{I}{T}$ is frequency of oscillation.

Here, $B_H = 5{\cdot}0 \times 10^{-2}$ T ; $\nu = 2{\cdot}0\ \text{s}^{-1}$

$$\therefore \quad I = \frac{0{\cdot}377 \times 5{\cdot}0 \times 10^{-2}}{4\pi^2 \times (2{\cdot}0)^2}$$
$$= \mathbf{1{\cdot}194 \times 10^{-4}\ kg\ m^2}$$

Problem 4.14. Two bar magnets having their momer of inertia in the ratio 1 : 1·5 oscillate in a horizontal plar with time periods of 2·5 s and 4·5 s respectively. Compar their magnetic moments. (*C.B.S.E. 200*

Sol. The time period of a bar magnet is given by

$$T = 2\pi\sqrt{\frac{I}{M B_H}}$$

Let M_1 and M_2 be the magnetic moments of the tw magnets ; and I_1 and I_2 be their moment of inertia. If T_1 ar T_2 are their respective time periods, then

$$\frac{T_1}{T_2} = \sqrt{\frac{I_1 M_2}{M_1 I_2}} \quad \text{or} \quad \frac{M_1}{M_2} = \frac{I_1}{I_2} \times \frac{T_2^2}{T_1^2}$$

Here, $\frac{I_1}{I_2} = \frac{1}{1{\cdot}5}$, $T_1 = 2{\cdot}5$ s and $T_2 = 4{\cdot}5$

$$\therefore \quad \frac{M_1}{M_2} = \frac{1}{1{\cdot}5} \times \frac{(4{\cdot}5)^2}{(2{\cdot}5)^2} = \mathbf{2{\cdot}16}$$

Problem 4.15. Two bar magnets placed together in vibration magnetometer take 3 s for 1 vibration. If or magnet is reversed, the combination takes 4 s for vibration. Find the ratio of their magnetic moments. (*H.S.S.C.E. 1998*

Sol. Here, $T_1 = 3$ s ; $T_2 = 4$ s

We know, $$\frac{M_1}{M_2} = \frac{T_2^2 + T_1^2}{T_2^2 - T_1^2} = \frac{4^2 + 3^2}{4^2 - 3^2} = \frac{16+9}{16-9} = \frac{25}{7}$$
$$= 3{\cdot}57$$

abc TECHIE STUFF – CONCEPTUAL NUMERICAL PROBLEMS

For ambitious, brilliant & curious Students

Problem 4.16. A telephone cable at a place has four long straight horizontal wires carrying a current of 1·0 A from east to west (in the same direction in all the wires). The earth's magnetic field at the place is 0·39 G and angle of dip is 35º. The magnetic declination is nearly zero. What are the resultant magnetic fields at points 4·0 cm below and above the cable ? (*Text Problem*)

Sol. Here, earth's magnetic field, $B = 0{\cdot}39$ G ; $\delta = 35°$

Therefore, horizontal component of earth's magnetic field,

$$B_H = B\cos\delta$$
or $$B_H = 0{\cdot}39\cos 35° = 0{\cdot}3195\ \text{G}$$

Vertical component of earth's magnetic field,

$$B_V = B\sin\delta$$
or $$B_V = 0{\cdot}39\sin 35° = 0{\cdot}2237\ \text{G}$$

Magnetic field produced by telephone cable having four wires,

$$B' = \left(\frac{\mu_0}{4\pi}\cdot\frac{2I}{a}\right) \times 4$$

Here, $I = 1{\cdot}0$ A, $a = 4{\cdot}0$ cm $= 4 \times 10^{-2}$ m

$$\therefore \quad B' = 10^{-7} \times \frac{2 \times 1{\cdot}0 \times 4}{4 \times 10^{-2}} = 0{\cdot}2 \times 10^{-4}\ \text{T} = 0{\cdot}2\ \text{G}$$

Resultant field below the cable : According to right har thumb rule, the direction of B′ at a point below the cable w be opposite to B_H.

Therefore, at a point 4 cm below the cable, resultar horizontal component of earth's field,

$$R_H = B_H - B' = 0{\cdot}3195 - 0{\cdot}2 = 0{\cdot}1195\ \text{G}$$

Resultant vertical component of earth's field,

$$R_V = B_V = 0{\cdot}2237\ \text{G (unchanged)}$$

Therefore, resultant earth's field,

$$R = \sqrt{R_H^2 + R_V^2} = \sqrt{0{\cdot}1195^2 + 0{\cdot}2237^2}$$
$$= \sqrt{0{\cdot}0143 + 0{\cdot}0500} = \sqrt{0{\cdot}0643} = \mathbf{0{\cdot}254\ G}$$

Resultant field above the cable : According to right har thumb rule, at a point above the cable, B′ will be in the sam direction as B_H. Therefore, at a point 4 cm above the cable

$$R_H = B_H + B' = 0{\cdot}3195 + 0{\cdot}2 = 0{\cdot}5195\ \text{G},$$
$$R_V = B_V = 0{\cdot}2237\ \text{G}$$

$$\therefore \quad R = \sqrt{R_H^2 + R_V^2} = \sqrt{0{\cdot}5195^2 + 0{\cdot}2237^2}$$
$$= \mathbf{0{\cdot}566\ G}$$

Problem 4.17. A short magnet of magnetic momer $5{\cdot}25 \times 10^{-2}\ \text{J T}^{-1}$ is placed with its axis perpendicul to the earth's field direction. At what distance from th centre of the magnet on (*i*) its normal bisector, (*ii*) its axi is the resultant field inclined at 45° with the earth's fiel Magnitude of the earth's field at the place is given to be 0· G. Ignore length of the magnet in comparison to th distances involved. (*Text Problen*

---

*In order to distinguish between the symbols for current and moment of inertia, current has been denoted by *i* (in place of I) in this problem.

Sol. Here, $M = 5{\cdot}25 \times 10^{-2}\ \text{J T}^{-1}$; $B_H = 0{\cdot}42\ \text{G} = 0{\cdot}42 \times 10^{-4}\ \text{T}$

(i) On its normal bisector : Fig. 4.15 shows the point P n the normal bisector of the magnet, where the resultant field is inclined at 45° with the earth's field.

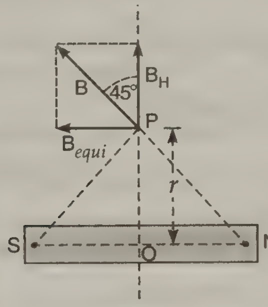

Fig. 4.15

It can happen only, if B_{equi} is equal to the horizontal omponent of the earth's field (B_H) *i.e.*

$$B_{equi} = B_H$$

For a short magnet, $B_{equi} = \dfrac{\mu_0}{4\pi} \cdot \dfrac{M}{r^3}$

$$\therefore \quad \frac{\mu_0}{4\pi} \cdot \frac{M}{r^3} = B_H$$

or $$r = \left(\frac{\mu_0}{4\pi} \cdot \frac{M}{B_H}\right)^{1/3} = \left(\frac{10^{-7} \times 5{\cdot}25 \times 10^{-2}}{0{\cdot}42 \times 10^{-4}}\right)^{1/3}$$

$$= (125 \times 10^{-6})^{1/3} = 5 \times 10^{-2}\ \text{m} = \mathbf{5{\cdot}0\ cm}$$

(ii) On its axis : Fig. 4.16 shows the point P on the axis f the magnet, where the resultant field is inclined at 45° with he earth's magnetic field.

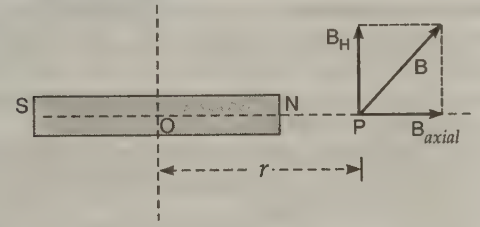

Fig. 4.16

It will be so, if

$$B_{axial} = B_H$$

For a short magnet, $B_{axial} = \dfrac{\mu_0}{4\pi} \cdot \dfrac{2M}{r^3}$

$$\therefore \quad \frac{\mu_0}{4\pi} \cdot \frac{2M}{r^3} = B_H$$

or $$r = \left(\frac{\mu_0}{4\pi} \cdot \frac{2M}{B_H}\right)^{1/3} = \left(\frac{10^{-7} \times 5{\cdot}25 \times 10^{-2}}{0{\cdot}42 \times 10^{-4}}\right)^{1/3}$$

$$= (250 \times 10^{-6})^{1/3} = 6{\cdot}3 \times 10^{-2}\ \text{m} = \mathbf{6{\cdot}3\ cm}$$

Problem 4.18. A compass needle free to turn in a horizontal plane is placed at the centre of a circular coil f 30 turns and radius 12 cm. The coil is in a vertical plane aking an angle of 45° with the magnetic meridian. When he current in the coil is 0·35 A, the needle points west to ast.

***(a)* Determine the horizontal component of the earth's agnetic field at the location.**

***(b)* The current in the coil is reversed and the coil is rotated about its vertical axis by an angle of 90° in the anticlockwise sense looking from the above. Predict the direction of the needle. Take the magnetic declination at the place to be zero.** *(Text Problem)*

Sol. *(a)* Horizontal component of earth's magnetic field (B_H) acts along magnetic N-S line. As the coil is placed in a vertical plane making angle 45° with magnetic meridian, the magnetic field B produced by the coil on passing current through it, will be along normal to the plane of the coil *i.e.* in a direction making angle of 45° with W-E line [Fig. 4.17].

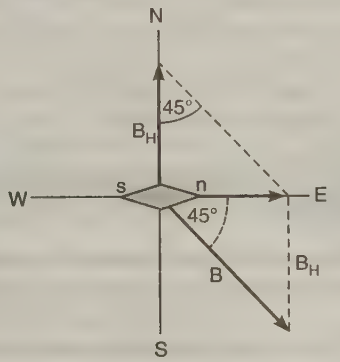

Fig. 4.17

The compass needle placed at the centre of the coil points west to east. Therefore, from the figure, it follows that

$$B_H = B \sin 45°$$

But magnetic field produced by the coil,

$$B = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a}$$

$$\therefore \quad B_H = \frac{\mu_0}{4\pi} \cdot \frac{2\pi n I}{a} \sin 45°$$

Here, $I = 0{\cdot}35\ \text{A}$; $n = 30$; $a = 12\ \text{cm} = 12 \times 10^{-2}\ \text{m}$

$$\therefore \quad B_H = 10^{-7} \times \frac{2\pi \times 30 \times 0{\cdot}35 \times 0{\cdot}707}{12 \times 10^{-2}}$$

$$= 3{\cdot}9 \times 10^{-5}\ \text{T} = 0{\cdot}39\ \text{G}$$

(b) The needle will reverse its original direction *i.e.* it will point *east to west.*

Problem 4.19. A small magnet A makes 10 vibrations in 90 seconds in earth's field. When another magnet B of short length is placed 0·1 m due south of the direction of earth's field, the magnet A makes 10 vibrations in 45 seconds. Calculate the magnetic moment of magnet B. Given that $B_H = 0{\cdot}34 \times 10^{-4}$ T.

Sol. *In earth's magnetic field* : Suppose I_1 and M_1 are values of moment of inertia and magnetic moment of the magnet A. Its time period of vibration in earth's magnetic field is given by

$$t_1 = 2\pi \sqrt{\frac{I_1}{M_1 B_H}} \qquad \text{...(i)}$$

In combined magnetic field of magnet B and B_H : Suppose time period of magnet A becomes t_2, when magnet B is placed due south. Since, magnet A lies on axial line of the magnet B, the magnet A vibrates in magnetic field

$$B_H' = B_H + B_{axial}$$

Here, B_{axial} is magnetic field on the axial line of the magnet B at the point, where magnet A vibrates.

$$\therefore \quad t_2 = 2\pi\sqrt{\frac{I_1}{M_1 B_H'}} \qquad ...(ii)$$

Dividing equation (*i*) by (*ii*), we have

$$\frac{t_1}{t_2} = \sqrt{\frac{B_H'}{B_H}} \quad \text{or} \quad B_H' = B_H\frac{t_1^2}{t_2^2}$$

$$\text{or} \quad B_H + B_{axial} = B_H\frac{t_1^2}{t_2^2}$$

$$\text{or} \quad B_{axial} = B_H\left(\frac{t_1^2}{t_2^2} - 1\right)$$

Here, $t_1 = \frac{90}{10} = 9\text{ s}; t_2 = \frac{45}{10} = 4.5\text{ s}$

and $B_H = 0.34 \times 10^{-4}$ T

$$\therefore \quad B_{axial} = 0.34\times10^{-4}\left(\frac{9^2}{4.5^2} - 1\right) = 1.02\times10^{-4}\text{ T}$$

If M_2 is magnetic moment of the magnet B (a short ba magnet), then

$$B_{axial} = \frac{\mu_0}{4\pi}\cdot\frac{2M_2}{r^3}$$

$$\therefore \quad \frac{\mu_0}{4\pi}\cdot\frac{2M_2}{r^3} = 1.02\times10^{-4}$$

Here, $\frac{\mu_0}{4\pi} = 10^{-7}\text{ T A}^{-1}\text{ m}$ and $r = 0.1$ m

$$\therefore \quad 10^{-7}\times\frac{2M_2}{(0.1)^3} = 1.02\times10^{-4}$$

or $\mathbf{M_2 = 0.51\ A\ m^2}$

FAQs FREQUENTLY ASKED VERY SHORT ANSWER QUESTIONS

With Answers/Hints

Q. 4.01. The earth's core is known to contain iron, but geologists do not regard this as a source of magnetic field. Why ? *(H.P.S.S.C.E. 2002)*

Ans. The temperature inside the earth is so high that it is impossible for the iron core to remain as a magnet and act as a source of magnetic field. The magnetic field due to earth is considered to be due to circulating electric currents induced in the iron in molten state and other conducting materials inside the earth.

Q. 4.02. Why does a bar magnet always stand in NS-direction, when suspended freely ? *(P.S.S.C.E. 2002)*

Ans. It is assumed that a huge magnet is lying deep inside the earth with its S-pole towards the geographical north and N-pole towards the geographical south.

Q. 4.03. What is geographic meridian ?

Ans. A vertical plane passing through the geographical N-S line is called geographical meridian.

Q. 4.04. What is magnetic meridian ? What is geomagnetic equator ? *(C.B.S.E. 1992)*

Ans. A vertical plane passing through the magnetic axis of the earth is called magnetic meridian.

The great circle on the earth's surface, whose plane is perpendicular to the magnetic axis is called magnetic equator.

Q. 4.05. Name the elements of earth's magnetic field. *(H.S.S.C.E. 2002, P.S.S.C.E. 1994)*

Or

Write the names of parameters of earth's magnetic field. *(P.S.S.C.E. 1999 S)*

Ans. Magnetic elements : declination, dip and horizontal component of earth's magnetic field.

Q. 4.06. Name the parameters needed to completely specify the earth's magnetic field at a point on the earth's surface. *(C.B.S.E. 1991)*

Ans. The parameters needed to completely specify the earth's magnetic field are declination, dip and horizontal component of earth's magnetic field.

Q. 4.07. A vector needs three quantities for its specification. Name the three independent quantities conventionally used to specify the earth's magnetic field. *(Text Question)*
